Sealing-wax. Before the composition of ordinary sealing-wax was known in Europe coloured beeswax was used for sealing letters and for attaching the impressions of seals to documents. Sealing-wax with Lac (q.v.) as the principal ingredient was probably first made in India or China, since it is only in these and neighbouring countries that the lac insect is found. Beckmann states that the use of sealing-wax made of lac was apparently very common among the Portuguese about the middle of the 16th century. The best red sealing-wax consists of shellac from 5 to 6 parts, Venice turpentine 3 to 4 parts, vermilion 3 to 4 parts, to which is frequently added 1½ part of magnesia, chalk, or gypsum, or a mixture of some of these. Inferior but still fairly good kinds have a considerably less amount of shellac and vermilion in their composition. Parcel-wax is made of shellac 3 parts, common resin 7 parts, turpentine 5¼ parts, chalk and gypsum together 3½ parts, and either vermilion 3 parts, or red-lead 6 parts. Bottle-wax is often made of pine-resin, turpentine, chalk, and some colouring matter; but it is very brittle unless about 10 per cent. of shellac is added.

In making sealing-wax the shellac and other materials are carefully melted in metal pans, and quickly stirred to prevent heavy colouring matter such as vermilion from falling to the bottom. The melted sealing-wax is then poured into metal moulds to form it into sticks, which are removed when cold. By one method the sticks are polished by spreading them on a table and passing a red-hot bar of iron over them. Another way is to hold them into a stove, and in either case till the surface just begins to melt. Sealing-wax is made in various colours, the finer qualities, however, being most largely in red. White, until recently, was chiefly coloured by subnitrate of bismuth, but a special kind of white-lead is now employed. Black is made by the addition of lampblack or vine-black to the other materials. For brown, umber is added; for blue, artificial ultramarine or Berlin blue; for green, Berlin blue and chrome-yellow; for yellow, either chrome-yellow (which will not stand a high heat) or ochre. For common wax some cheaper colouring materials are used, such as baryta for a white. Aniline colours have been tried for sealing-wax with some promise of success.

Sea-lion. See SEAL.

Seal Islands, a name for Lobos Islands (q.v.).

Sealkote. See SIALKOT.

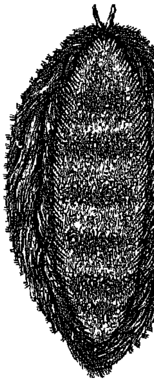
Sea-margins. See BEACHES.

Sea-mat (*Flustra*), a very common genus of Polyzoa (q.v.), various species of which are among the commonest objects in the wrack of the seashore. The colonies are somewhat seaweed-like, but all over the flat leaf-like growth may be seen the minute chambers in which the individuals lived. The texture is horny, whence another common name—hornwrack. Those found on shore are usually dead, having been torn from their natural moorings on rocks, seaweed, or marine animals. Fresh specimens have a characteristic musky odour.

Seamen are technically those persons, below the rank of officer, who are employed in navigating decked vessels on the high seas. See CREW, CRIMP, DESERTION, NAVY.

Sea-mew. See GULL.

Sea-mouse (*Aphrodite*), a genus of Chætopod worms, well represented by *A. aculeata*, the common British species. This worm has a compact oval body, 4 to 6 inches in length by 1 to 2 in breadth, and is thickly covered with silky hairs, whose structure is such as to produce brilliant iridescence. Along the back these hairs form a matted feltwork, protecting a double row of flat plates, in part respiratory. The ventral appendages, by means of which the sea-mouse creeps along the floor of the sea, bear bundles of very strong bristles. The head bears tentacles and eyes. Internally the animal is remarkable on account of the very much branched character of the gut. The home of the sea-mouse is at the bottom of fairly deep water, but storms often throw them ashore.



Sea-mouse (*Aphrodite aculeata*).

Sea-nettle. See ACALEPHÆ.

Sea-owl, a name for the Lumpsucker (q.v.).

Sea-pen, a name sometimes applied to Pennatula (q.v.), sometimes to the chitinous, quill-like structure which lies along the posterior surface of the squid and some related cuttle-fish.

Sea-pie. See OYSTER-CATCHER.

Sea-pike (*Centropomus undecimalis*), an edible American fish, occurring on the Florida and Texas coasts. The genus includes several somewhat pike-like fishes, at home in the warm American seas, though often thriving in fresh water. In reality they are allied to the perches, not to the pikes. On British coasts the term sea-pike is sometimes applied to the garfish or Belone.

Sea-pink. See THRIFT.

Sea-porcupine. See DIODON.

Search-light. See NAVY, Vol. VII. p. 421.

Search-warrant, an authority granted to an officer of police, empowering him to enter premises and to search for and seize property. In England such warrants seem to have been illegal at common law; they were first permitted by statute for seizing stolen goods in 1782. Under acts now in force a justice of the peace may grant warrants to search for stolen goods, false coin, forged bank-notes, &c.; he may also give a warrant to search any place where there is reasonable cause to suspect that an explosive substance or machine is concealed for a felonious purpose.

The right of searching ships on the high seas indisputably belongs to belligerents (see ENEMY, CONTRABAND, NEUTRALITY). The right claimed by England to search United States ships for British subjects on board, with a view to impress them into the British naval service, was one of the causes of war in 1812; and the right of search for slaves on board suspected slave-traders was repeatedly a source of difficulty. The case of the *Trent* (q.v.) in 1861 nearly led to war between Britain and the United States.

The proper officers have a right to search the persons of apprehended thieves, &c.; and custom-house officers are entitled to search for smuggled goods, not merely ships but all persons on board them or who land from them. But any person may insist, before being searched, on being taken before a magistrate or superior custom-house officer and raise the question whether there is reasonable suspicion that he has smuggled goods about him.

Sea-robin, a common American name for fishes of the genus Prionotus, which represents in America the European gurnards (Trigla).

Sea-scorpion. See FATHER-LASHER.

Sea-serpent, the name given to gigantic animals, presumedly of serpentine form, which have been frequently described by sailors and others, and which are believed by many naturalists to exist in the sea-depths, especially in tropical oceans. The question of the existence of a sea-serpent has long formed one of the knotty problems of zoological science. But it seems reasonable to conclude that there exists a certain basis for the supposition that huge undescribed marine forms do exist in the sea-depths, and that the most reliable tales of sea-serpents take origin from appearances of such animals. Of such tales possessing a warrantable basis of fact, and emanating from authoritative sources, that of Captain M'Quhae is one of the best known. This account was published in 1848. Captain M'Quhae commanded H.M.S. *Dædalus*, and encountered the serpentine form in 24° 44′ S. lat. and 9° 20′ E. long., and therefore in the South Atlantic Ocean, near the Tropic of Capricorn, and not very far from the coast of Africa. It was not, as in other cases, in bright and fine weather, but in dark and cloudy weather, and with a long ocean swell. The animal was swimming rapidly, and with its head and neck above water. Captain M'Quhae in his report to the Admiralty describes it with confidence as 'an enormous serpent, with head and shoulders kept about 4 feet constantly above the surface of the sea;' and he adds: 'As nearly as we could approximate by comparing it with the length of what our maintopsail-yard would show in the water, there was at the very least 60 feet of the animal *à fleur d'eau*, no portion of which was, to our perception, used in propelling it through the water, either by vertical or horizontal undulation. It passed rapidly, but so close under our lee-quarter that had it been a man of my acquaintance I should have easily recognised his features with the naked eye; and it did not, either in approaching the ship or after it had passed our wake, deviate in the slightest degree from its course to the south-west, which it held on at the pace of from 12 to 15 miles per hour, apparently on some determined purpose. The diameter of the serpent was about 15 or 16 inches behind the head, which was without any doubt that of a snake; and it was never during the twenty minutes that it continued in sight of our glasses once below the surface of the water; its colour a dark brown, with yellowish white about the throat. It had no fins, but something like the mane of a horse, or rather a bunch of seaweed, washed about its back.' Regret has been very naturally expressed that Captain M'Quhae did not bestow a shot on it. Figures prepared from a sketch by him were published in the *Illustrated London News* of 28th October 1848. About the same time the testimony of another witness, Lieutenant Drummond, appeared, and was found to differ in some important points from the account of the animal given by Captain M'Quhae and the figures published with his approbation, particularly in ascribing a more elongated form to the head, in the mention of a back-fin, whereas Captain M'Quhae expressly says that no fins were seen, and in a lower estimate of the length of the portion of the animal visible. Lieutenant Drummond's words are: 'The appearance of its head, which with the back-fin was the only portion of the animal visible, was long, pointed, and flattened at the top, perhaps 10 feet in length; the upper jaw projecting considerably; the fin was perhaps 20 feet in the rear of the head, and visible occasionally; the captain also asserted that he saw the tail, or another fin about the same distance behind it; the upper part of the head and shoulders appeared of a dark-brown colour, and beneath the under jaw a brownish white. It pursued a steady and undeviating course, keeping its head horizontal with the water, and in rather a raised position, disappearing occasionally beneath a wave for a very brief interval, and not apparently for the purposes of respiration. It was going at the rate of perhaps from 12 to 14 miles an hour, and when nearest was perhaps 100 yards distant. In fact, it gave one quite the idea of a large snake or eel.' Lieutenant Drummond's account is the more worthy of regard, as it is derived from his log-book, and so gives the exact impressions of the hour, whilst Captain M'Quhae's was written from memory after his arrival in England. Sir Richard Owen thought the animal was a gigantic seal; a supposition, however, which does not at all agree with the description given.

In 1875 a battle between a sea-serpent and a whale was viewed from the deck of the *Pauline* of London, Captain Drevar, when proceeding with a cargo of coals from Shields to Zanzibar. When the *Pauline* reached the region of the trade-winds and equatorial currents she was carried out of her course, and after a severe storm found herself off Cape San Roque, where several sperm-whales were seen playing about her. While the crew were watching them they suddenly beheld a sight that filled every man on board with terror. Starting straight from the bosom of the deep, a gigantic serpent rose and wound itself twice in two mighty coils round the largest of the whales, which it proceeded to crush in genuine boa-constrictor fashion. In vain did the hapless whale struggle, lash the water into foam, and even bellow, for all its efforts were as nothing against the supernatural powers of its dreadful adversary; whose strength may be further imagined from the fact that the ribs of the ill-fated cetacean were distinctly heard cracking one after the other with a report like that of a small cannon.

Of no less a ship than H.M. yacht *Osborne* the captain and officers in June 1877 forwarded an official report to the Admiralty containing an account of a sea-serpent's appearance off the coast of Sicily on the 2d of that month. 'The time was five o'clock in the afternoon. The sea was exceptionally smooth, and the officers were provided with good telescopes. The monster had a smooth skin, devoid of scales, a bullet-shaped head, and a face like an alligator. It was of immense length, and along the back was a ridge of fins about *fifteen* feet in length and *six* feet apart. It moved slowly, and was seen by all the ship's officers.' This account was further supplemented by a sketch from the pencil of Lieutenant W. P. Hynes of the *Osborne*, who to the above description adds that the fins were of irregular height, and about 40 feet in extent; but, 'as we were passing through the water at 10½ knots, I could only get a view of it "end on."' It was about 15 or 20 feet broad at the shoulders, with flappers or fins that seemed to have a semi-revolving motion. 'From the top of the head to the part of the back where it became immersed I should consider about 50 feet, and that seemed about a third of the whole length. All this part was smooth, resembling a seal.' These instances are but examples of the many cases in which narratives of the most circumstantial character have been recorded regarding the appearance of serpentine animals, usually in tropical seas.

As will readily be admitted, the chief point at issue is that of the zoological determination of the forms reported to have been seen. Gigantic cuttle-fishes, now proved to have a veritable existence, might in many cases imitate an elongated marine form, swimming near the surface of the sea. It is by far the most plausible theory of sea-serpent existence to suppose that most of the animals described are really giant cuttle-fishes of the Loligo or squid type. These creatures may attain a length of 40 feet or more inclusive of their tentacles, and as they swim along the surface of the sea backwards the tail-fin might well be mistaken for a serpentine head and its fin or ridge, while the tentacles and wash produced by the animal's movements would impart an exaggerated length to the body. Even the incident already described in the case of the *Pauline* might be explicable on the theory that giant cuttle-fishes attacked the whales, and that the so-called serpents were really the arms or tentacles of the squids. As regards the *Pauline* case, it may be remarked that the latitude in which the incident occurred was one most unlikely for any sea-snakes to be found. Certain fishes, too, such as the Basking Shark (*Selache maxima*), would also under certain circumstances appear as unusual marine forms; and, as the present writer has pointed out, the well-known Tape-fishes (*Gymnetrus banksii*) and other Ribbon-fishes would very accurately reproduce the features of a marine snake, especially when these fishes, as sometimes happens, have grown to an immense size. The marine snakes or Hydrophidæ of the Indian Ocean would also serve to personate the 'great unknown' if unusually large. It seems certain that in the immense development of ordinary marine animals may be found a probable clue to the sea-serpent mystery. Mr P. H. Gosse entertained the notion that it might be possible to explain certain sea-serpent stories on the theory that some of the gigantic marine reptiles with whose fossils we are well acquainted might still be in existence in the sea-depths, and occasionally make their appearance at the surface of the ocean. Cases of mere serpentine appearances assumed by certain animals are not to be confused with cases in which a single animal has presented a serpentine aspect. Flocks of the birds known as shags swimming close to the water's edge might personate a sea-serpent swimming along the top of the water; but a flock of birds would have been readily detected by Captain M'Quhae, and by many other observers who have beheld the unknown form from a relatively near distance.

Apart altogether from these historical or semi-historical examples, the sea-serpent has had continuous existence in folklore everywhere, whether among the Eskimo, Fijians, Japanese, Icelanders, Basques, Red Indians, or Chinese. The notion is natural and easy of belief, and the human desire for wonders is sufficient to account for any belief.

See C. Gould, *Mythical Monsters* (1886); F. S. Bassett, *Legends and Superstitions of the Sea* (Chicago, 1886); J. Gibson, *Monsters of the Sea* (1886); and a paper on 'The Sea-serpents of Science,' in the present writer's *Leisure-time Studies* (1884).

Seashore, or land bordering on the sea, belongs partly to the crown, and the public have certain rights in relation thereto. The soil or property in the foreshore (land between high and low water mark) is vested in the crown, and the limit on the land side is defined to be the medium line of high-water of all the tides in the course of the year, or the height of the medium tides in each quarter of a lunar revolution during the whole year. But though the crown is *primâ facie* the owner of the seashore, the owner of the adjoining manor has sometimes a grant of it, and he may prove this grant by ancient use—such as gathering seaweed, &c. The public have a right to walk on that part of the shore vested in the crown, but they have no right to trespass on the adjacent lands in order to get at the shore, so that it is only where a highway leads to the shore, or the public land from seaward, that the right can be made available. Thus it has been decided that the public have no legal right to trespass on the adjoining lands in order to get to the shore for the purpose of bathing. The public have a right to fish on the seashore if they get legal access to it, and may take all floating fish, but not oysters or mussels which adhere to the rock, if the soil belongs to an individual. The public have no right to gather seaweed or shells, though, as regards the latter, it is of so little consequence that nobody prevents them. Nor have fishermen a right to go on that part of the seashore which is private property to dig sand for ballast, or to dry their nets, or similar purposes, though in a few cases local customs permitting a limited class of persons (e.g. the fishermen of a township) to exercise such rights have been held valid. In Scotland the right to the seashore is also vested in the crown; when a crown grant gives land bounded by the seashore, this is held to give to the grantee the foreshore also. See Stuart A. Moore, *History and Law of the Foreshore* (3d ed. 1888); and BEACHES (RAISED), DENUDATION, DERELICT, DRIFT, SAND, UPHEAVAL.

Sea-sickness is a variety of vomiting deserving of special notice. It is often preceded by premonitory symptoms, which appear almost immediately after a susceptible person is exposed to the motion of rolling water in a vessel or boat, and are as distressing as the vomiting itself. Amongst these symptoms may be mentioned vertigo and headache, with a peculiar feeling of sinking and distress about the pit of the stomach. Vomiting, however, in general, soon comes on, accompanied with convulsive heaving of the stomach, and such an indescribable feeling of prostration as to render the patient utterly regardless of what is going on around him, and almost indifferent to life. Moreover, pallor and cold sweat are commonly present, with disturbance of the action of the bowels, usually constipation, but occasionally diarrhœa. The susceptibility to this troublesome affection varies extremely in different persons. Some never suffer from it, others only on their first voyage, and others, again, like Nelson, in every fresh voyage they take; with some it continues but a few hours, while others suffer almost continuously throughout a long voyage. In the great majority of cases the sickness disappears in a few days, unless the weather be very boisterous. It almost always ceases on landing, although more or less giddiness may prevail for some hours. Though a very distressing malady it is rarely serious, but sometimes is so severe and prolonged as to prove fatal. Infants and aged persons are supposed to possess a comparative immunity from sea-sickness, while as a general rule women suffer more than men. According to Dr Althaus, persons with a strong heart and a slow pulse generally suffer little from sea-sickness, while irritable people, with a quick pulse and a tendency to palpitation, are more liable to be affected; and he thus accounts for different liability of different nations to this affection; 'for, as a rule, the French and Italians being of a more irritable temper suffer most from the disorder, the Germans less, and the English least.'

The primary cause (or rather condition) of sea-sickness is the motion of the ship; and the *pitching* of a vessel, or alternate rising and falling of the bow and stern, is especially apt to produce it. It is less felt in large and heavily ballasted vessels, because the movements referred to are least perceptible in them. Other more or less regularly repeated oscillatory movements produce a precisely similar condition in some people; the motion of a swing or a toboggan in particular. Some suffer in a railway journey, especially when sitting with their backs to the engine; while a few individuals are so intensely susceptible that even a short drive in a carriage or omnibus is enough to induce nausea and vomiting.

The mode in which such causes produce sea-sickness has been much discussed; but it is now generally believed to be by a reflex disturbance of the nervous system, induced by the unusual and violent stimulation of the sensory organs concerned in the maintenance of the equilibrium of the body, particularly the semicircular canals (see EAR) and the eyes, and also of the viscera, particularly the stomach. This is not inconsistent with the view of Dr Chapman, who gave much attention to the subject, and held that the motions of the vessel cause the accumulation of an undue amount of 'blood in the nervous centres along the back, and especially in those segments of the spinal cord related to the stomach, and the muscles concerned in vomiting.' He accordingly believed that the only scientific and really effective remedy for this disorder must be one which has the power of lessening the amount of blood in the whole of the nervous centres along the back, and this can be done by lowering the temperature of the spinal region by the local application of ice. For a description of Dr Chapman's 'spinal ice-bags' (which may be obtained from any respectable surgical instrument-maker), and for the method of applying them, we must refer to his work *On Sea-sickness* (1864). They have undoubtedly proved of great value in many cases. Another method of treatment, which is less difficult to employ and sometimes gives good results, is to make the sufferer breathe deeply and regularly, timing the respirations by the watch at about fifteen to the minute.

Those who are susceptible to this distressing affection and have not the opportunity of trying the ice-bags, may, at all events, diminish the severity of the vomiting by assuming, and as long as possible retaining, the horizontal position as nearly as possible in the centre of the ship's movement, and keeping the eyes closed. Compression of the abdomen by means of a broad tight belt sometimes gives relief. Fresh air and light diet are undoubtedly of great importance. A little arrowroot, flavoured with brandy or sherry, is usually a kind of food that will most easily remain on the stomach, when the severity of the symptoms is abating. The maintenance of the surface temperature, by warm blankets and hot bottles if necessary, should be attended to. The application of a mustard poultice or stimulating liniment to the epigastrium is often useful. Sucking or swallowing small lumps of ice also tends to diminish the tendency to vomiting. As soon as possible the sufferer should go on deck, and try to move about; if this can be done the nervous system undoubtedly becomes more quickly accustomed to the unwonted conditions under which it is placed.

With regard to drugs, no specific has been discovered, nor is it likely that there ever will be. But something can often be done by medication both before and during a voyage. First in importance are purgatives. The bowels should be freely relieved the day before the voyage begins, and should never be allowed to become constipated. The administration of a tonic (e.g. Easton's syrup) for a few days before starting is also useful; and regular doses of the bromides, commenced just before going on board, sometimes diminish the intensity of the malady. When it has set in, chloroform (a few drops on a piece of sugar), opium, chloral may do good; and cocaine, nitrite of amyl, nitroglycerine, and antipyrin, drugs more recently introduced, have all been strongly recommended. But with all such remedies disappointment is only too common.

See Dr T. Dutton, *Sea-sickness* (2d ed. 1891); and a small monograph by Rosenbach (Berlin, 1891).

Seaside Grape (*Coccoloba uvifera*), a small tree of the natural order *Polygoneæ*, a native of the West Indies. It grows on the seacoasts, and receives its name from the bunches of its violet-coloured fleshy calyx which envelop the nuts or seeds. The fleshy part is pleasantly acid, and is eaten with or without sugar; it is esteemed astringent and antidysenteric; is used in making refreshing drinks. The extract of the wood is extremely astringent, and is sometimes called Jamaica Kino. The wood itself is heavy, hard, durable, beautifully veined, and capable of taking a fine polish.

Sea Slug. See HOLOTHURIANS.

Sea-snakes (Hydrophidæ), very venomous marine snakes, inhabiting the tropical parts of the Indian and Pacific Oceans, especially about the East Indian Archipelago, and between China and Australia. The body is compressed behind, and the tail is often markedly paddle-shaped; the ventral scales are very slightly if at all specialised; the nostrils are valved, and lie on the tip of the snout; the eyes are small, and most of the sea-snakes are very blind and helpless when taken out of the water; the fangs are like those of cobras, and the venom is very virulent. The sea-snakes feed on fishes, which they kill almost instantly with their poison and swallow head foremost. They are themselves preyed upon by sharks and rays. They not unfrequently attain a length of eight feet, but are not large enough to be mistaken for 'sea-serpents.' All are viviparous. Among the common forms are species of *Hydrophis* and the yellow-bellied *Pelamys bicolor*, while the genus Platurus is in several ways half-way between the typical Hydrophidæ and the terrestrial Elapidæ.

Seasons. In the article EARTH the motions of the earth on which the changes of the seasons ultimately depend are explained. The chief cause of the greater heat of summer and cold of winter is that the rays of the sun fall more obliquely on the earth's surface in the latter season than in the former (see CLIMATE). Another concurrent cause is the greater length of the day in summer, and of the night in winter. Within the tropics the sun's rays have at no time so much obliquity as to make one part of the year very sensibly colder than another. But the zone of equatorial calms in which rainfall is practically continuous is shifted northward when the sun moves northward in the northern summer, and is similarly shifted southward in the southern summer. As the wet-zone swings to and fro, following the sun, the regions it traverses experience alternate wet and dry seasons. Those regions lying near the mean position of the wet-zone have thus two wet and two dry seasons in the year, the regions near its extreme positions having one wet and one dry season. Wet and dry seasons are also produced by the Monsoons (q.v.), themselves due to the relative seasonal change of temperature between land and sea (see also RAIN). In the temperate regions of the globe the year is naturally divided into four seasons—*Spring*, *Summer*, *Autumn*, and *Winter*. In the arctic and antarctic regions spring and autumn are very brief, and the natural division of the year is simply into summer and winter, the winter being long, and the summer short; and this is very much the case also in regions of the temperate zones lying near the arctic and antarctic circles. In subtropical regions the distinction of four seasons is, in like manner, very imperfectly marked. Conventionally (as in almanacs) it is assumed that each season commences at the equinox or solstice—e.g. that in the northern hemisphere spring commences at the vernal equinox about March 20, and summer at the summer solstice on June 21, although this is popularly spoken of as 'Midsummer Day;' and the 'summer months' in common English parlance include May, June, and July, winter being November, December, and January, and spring and autumn accordingly. Practically our division of the seasons depends more on seedtime and harvest than on the extremes of annual heat and cold. The greatest heat of summer is reached a considerable time after the summer solstice, the period when the sun's rays are most nearly vertical, and the day is longest. The greatest cold of winter in like manner occurs after the winter solstice—the period when the day is shortest, and the sun's rays are most oblique. The reason in the former case is that as summer advances the earth itself becomes more heated by the continued action of the sun's rays; in the latter, that it retains a portion of the heat which it has imbibed during summer, just as the warmest part of the day is somewhat after mid-day, and the coldest part of the night is towards morning. The four seasons of temperate regions are distinguished by the phenomena of plant-life, such as the budding, blossoming, fruit-bearing, and leafless repose of deciduous trees. Associated with these annual changes there are modifications of structure and function adapted to the seasonal variation of climate in different localities. Similar habits of Hibernation (q.v.) or of change in the thickness and colour of fur or feathers are found in the animals of regions where the seasons are sharply contrasted in climate. The intellectual superiority of the races inhabiting temperate regions is in part traceable to the constant necessity for forethought in providing for the regularly recurring season of winter when natural resources cease to be available.

Sea-spider. See PYCNOGONIDÆ; and for the Spider-crab, CRAB.

Sea-squirt, a popular name for any of the Ascidians (q.v.); also called Sea-perch, Sea-pear, Sea-pork, &c.

Sea-surgeons (Acronuridæ), a family of spiny-rayed Teleostean fishes, living in tropical seas, especially near coral-reefs. The name refers especially to the members of the genus *Acanthurus*—characterised by a lancet-like spine which lies ensheathed on each side of the tail, but can be erected as a formidable weapon.

Sea-swallow. See TERN.

Seathwaite, a valley and hamlet at the head of Borrowdale (q.v.) in Cumberland, remarkable for its heavy rainfall. See RAIN.

Sea-trout, a popular name for various species of the genus Salmo, but especially for the common *Salmo trutta* (see SALMON).

Seattle (pron. *Se at'tel*), capital of King county, Washington, is on Elliott Bay, an arm of Puget Sound, 18 miles by rail N. of Tacoma. The residence streets run up the slope of a hill, with the business portion built on the level ground at the foot, stretching along the excellent harbour, with its many wharves. Seattle owes its phenomenal growth to the development of the state lumber trade, of which it is the chief seat. Over 1000 vessels of about 1,000,000 tons enter and clear the port annually, carrying away coal and timber. Shipbuilding and a busy fishery are also carried on. There are cable and electric tramways, and the town possesses a university. In 1889 a terrible fire destroyed the whole business portion—sixty blocks—with the wharves, and cost nearly $10,000,000; but within a year 265 new buildings, mostly of iron and stone, besides sixty wharves, with a frontage of 2 miles, were erected. Pop. (1880) 3533; (1890) 42,837.

Sea-unicorn. See NARWHAL.

Sea-urchins (*Echinoidea*), a class of Echinoderms. In the more typical genera, such as Echinus, the body is symmetrical and nearly globular; others, such as Spatangus, are heart-shaped; and others, such as Clypeaster, are shield-shaped and flattened. In all cases the body is walled in by continuous plates of lime, which, though capable of independent growth, are rigidly connected, except in Echinothuridæ, which have plastic shells, as the extinct Palæo-echinoidea seem also to have had.

In a typical sea-urchin, such as *Echinus esculentus* or *Strongylocentrotus lividus*, the body is a slightly flattened sphere, covered with movable spines. The food-canal begins in the middle of the lower surface, and ends at the opposite pole in the

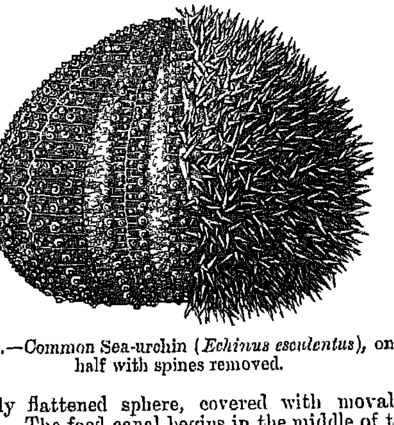


Fig. 1.—Common Sea-urchin (*Echinus esculentus*), one-half with spines removed.

middle of an 'apical disc,' which consists of a central plate surrounded by five 'ocular' and five 'genital' plates. The ocular plates bear eye-specks; the genital plates bear the openings of the genital ducts, but one of the five is modified as a madreporic plate through which fluid enters and leaves the water-vascular system. From pole to pole extend ten meridians—each a double row of calcareous plates which fit one another firmly. Five of these meridians—in line with the ocular plates—are known as ambulacral areas, for through holes in their plates the locomotor tube-feet are extruded; the other five meridians, alternating with the former and in line with the genital plates, are called inter-ambulacral areas, and bear spines, not tube-feet. The bases of the spines fit over ball-like knobs, on which they are moved by muscles. There are also two peculiarly modified forms of spines—the minute pedicellariæ, with three snapping-blades mounted on a soft stalk, and small globular sphæridia which seem to be sensitive to chemical changes in the water. The pedicellariæ have been seen removing pieces of seaweed and the like from the surface of the shell. In front of the mouth project the tips of five teeth which work against one another, grasping and grinding small particles. They are fixed in five large sockets, and along with fifteen other pieces form 'Aristotle's lantern,' a complex, somewhat lantern-like masticating mill, of which Aristotle took notice. The limy skeleton is formed in the mesoderm, and outside of it there is a delicate ciliated ectoderm with a network of nerve-fibres and some ganglion cells. Inside the shell, lining the spacious body cavity, there is again ciliated epithelium.

The nervous system consists of a ring around the mouth, with a radial branch up each ambulacral area, and of the superficial network. The tube-feet, pedicellariæ, and spines are all under nervous control, while the eye-specks, the sphæridia, and the tube-feet adjoining the mouth are especially sensitive. The alimentary canal passes through Aristotle's lantern, coils round the inside of the shell, and ends in the apical disc. The body-cavity contains a fluid with floating brown cells apparently of some significance in respiration.

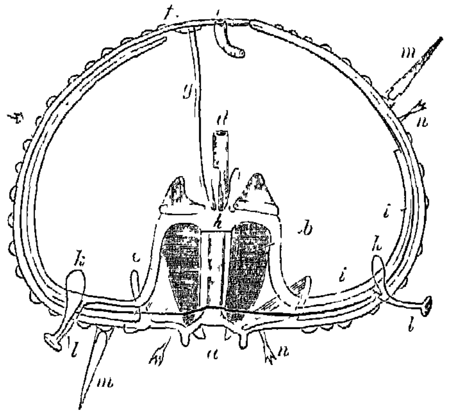

Fig. 2.—Diagram showing the Anatomy of Sea-urchin (after Huxley):
a, mouth; *b*, teeth of Aristotle's lantern; *c*, muscles which work the lantern; *d*, food-canal; *e*, end of food-canal; *f*, madreporic plate; *g*, stone-canal; *h*, circular water-vessel; *i*, radial water-vessel; *k*, ampulla; *l*, tube-foot; *m*, spine; *n*, pedicellaria.

The water-vascular system is of use in locomotion, and perhaps also in excretion. From the apical madreporic plate a 'stone-canal' extends through the body to a circular vessel round the upper end of the lantern; this circular vessel gives off five radial vessels, from which the tube-feet are supplied. When filled with fluid the tube-feet become tense and are pressed against the surface of the rock; when the fluid flows back they adhere firmly, and the sea-urchin drags itself towards the attachment. There is a blood vascular system, but it is difficult to trace. Respiration seems to be discharged in part by the body-cavity fluid, in part by ten hollow outgrowths on the area round about the mouth.

The sexes are separate and resemble one another. The reproductive organs are five spongy masses lying beneath the apical disc. The eggs are fertilised externally by spermatozoa wafted from another sea-urchin; and the free-swimming larva out of which the adult develops, as in other Echinoderms, by a remarkable indirect metamorphosis, is called a Pluteus, and has a quaint form, a little suggestive of a many-legged painter's easel. A few sea-urchins—e.g. Hemiaster—carry their young about with them among their spines.

Most sea-urchins live off rocky coasts; not a few shelter themselves in holes in the rocks; many deep-sea forms are known. Most are very sluggish, moving slowly by means of their tube-feet, in some cases slightly helped by their spines, in other cases perhaps hindered. They feed in part on seaweeds, mostly on organisms and organic matter found in mud and other deposits. Many look as if they were falling victims to their constitutional tendency towards the deposition of lime, for there is hardly any part of the body which may not become limy, and in some of the flattened forms the body-cavity is much restricted by cross beams of lime.

Among other Echinoderms, the Echinoids may be placed near Asteroids (starfishes) on the one hand, and near Holothuroids (sea-cucumbers) on the other, while they have without doubt affinities with the extinct Cystoids, which occupy a central position among the classes. The sea-urchins are often classified as follows:

1. PALÆO-ECHINOIDEA.—Extinct forms, apparently with plastic shells, occurring first in Lower Silurian rocks.
2. DESMOSTICHA.—Regular and symmetrical forms, such as Echinus, Strongylocentrotus, Cidaris (with very long spines), Diadema (with numerous diffuse eyes), *Cyanosoma urens* (with poisonous spines), Echinothuridæ (with flexible shells).
3. CLYPEASTROIDEA.—Shield-shaped and often flattened forms, with the end of the food-canal outside the apical disc—e.g. Clypeaster.
4. PETALOSTICHA.—Heart-shaped forms, with excentric mouth, without masticating organs, with the end of the food-canal away from the apical disc, with irregular ambulacral areas—e.g. Spatangus.

The ovaries of *Echinus esculentus* are sometimes eaten, but otherwise the sea-urchins hardly come into touch with human life.

Seaweeds, a general and popular term applied to a vast collection of lower plant-forms growing on the seacoast from high-water mark (or a little above that limit) to a depth of from 50 to 100 fathoms (rarely deeper), and all belonging to the sub-class of the Thallophyta, to which the name Algæ has been given (see ALGÆ). Any *detailed treatment of the organisms included under* the term would be impossible within the limits of a short article like the present. It must suffice, on the one hand, to indicate the chief variations in structure and life-history of typical representatives, and on the other to refer briefly to the more important points in the distribution and classification of the group. The short bibliography appended will supply a guide to the very extensive literature of the subject.

An examination of an average shore-belt exposed at ebb-tide reveals the fact that this area may be roughly divided into four regions: (*a*) a zone at and above high-water mark, characterised by the predominance of filamentous and encrusting, often inconspicuous, forms, exhibiting a bluish green colour when examined under the microscope; (*b*) a zone from near high-water mark to half-tide level, occupied chiefly by algæ of a bright grass-green tint; (*c*) from half-tide level to low tide mark, where the majority of the plants are olive-brown in colour; and finally (*d*) from near low-water mark to depths never exposed by the lowest ebb, where the preponderance of forms are of a distinctly red colour. Although not a few shores exhibit these zones fairly clearly, it must be remembered that, owing to the nature of the shore, the character of the tides, and the absence or presence of large influxes of fresh water, the zoning is not always clearly defined. For instance, the uppermost zone of blue-green forms is most likely to be met with on low-lying coast-lines where the seashore proper merges gradually into brackish marshes and muddy pools, such as, for example, the estuaries of the Dee and Mersey, or of the Clyde near Dumbarton. Grass-green forms are most plentiful on shelving rocky shores; whilst on such steep rocky shores as those of the fjords of the west coast of Scotland olive-brown seaweeds form the prevailing vegetation right up to high-water mark. It must be also borne in mind that certain species of algæ are invariably found in regions of the littoral area not characteristically occupied by the majority of forms of a similar hue. Thus the common dwarf species, *Pelvetia canaliculata*, closely allied to the familiar bladder-wrack (*Fucus vesiculosus*), belongs to the olive division of seaweeds, and yet is invariably found at or even above high-water mark. Tangle (*Laminaria digitata*), also an olive seaweed, is, on the other hand, a deep-water form only exposed at low tides, whilst the genus Struvea, one of the pure-green algæ, may be dredged from 30 fathoms. Very many red algæ are found under cover of the olive forms between tide marks, whilst some have their habitat at or above high-water mark. For example, two species of the genus Rhodochorton form a crimson velvety pile on rocks from half-tide level to far above high-water mark, and another and easily recognisable form, *Catenella opuntia*, grows on the lee side of rocks which are seldom touched by the flood-tide.

It is worthy of note that the classification of seaweeds into four groups according to colour is strikingly supported by the morphology and life-history of the forms so brought together. This fact becomes all the more remarkable when it is remembered that colour among higher plants is in very few cases of even specific value in classification. The blue-green algæ are known as Cyanophyceæ, the pure-green as Chlorophyceæ, the olive as Phæophyceæ, and the red as Rhodophyceæ. (By some authors the lower members of the first two groups are classed together under the name of Protophyceæ.) All possess the green colouring matter chlorophyll, but in the blue, olive, and red forms additional colouring matters (phycocyanin, phycophæin, and phycoerythrin) are present to a greater or less extent, masking the pure-green tint so well seen in the Chlorophyceæ. It is impossible in the present state of our knowledge to dogmatise on the precise value of these additional pigments, but we cannot be far wrong in saying that they are associated with the modification of the intensity or quality of sunlight, and aid or protect the chlorophyll in the peculiar and vitally important duties which it performs in the nutrition of the organism (see CHLOROPHYLL). It has been ascertained that certain rays of the solar spectrum are more efficient than others in the work of assimilation, and it is worthy of note that these rays are precisely those which are first intercepted in the passage of sunlight into sea water. Our ignorance of the important physiological problems involved may be estimated when we place against this explanation the fact that Kjellman in his exploration of the flora of the Arctic Sea found that algæ grew and reproduced at a mean temperature of $-1°$ C. and during the long and dark arctic night of three months' duration.

Turning from the bathymetric distribution of seaweeds to their surface distribution, we find here also many interesting and difficult problems. In the first place the medium in which seaweeds live is of a more uniform temperature than that to which land plants are exposed, although against this we must place the fact that seaweeds are more susceptible to fluctuations of temperature. Whilst ocean currents are undoubtedly the chief agents in the transport of the marine flora, long tracts of deep ocean must prove serious barriers to the migration of littoral species. It is scarcely necessary to point out that continental areas, hotter and colder regions of the sea, and long stretches of sandy shore must also act as barriers to possible migration. The effects of such barriers are well seen in comparing the floras of the tropical Atlantic and of the Indian Ocean, the north and south temperate Atlantic, and the eastern and western shores of the same great ocean. From the following table (abstracted from Murray's paper on the 'Distribution of Marine Algæ,' *Trans. Biol. Soc. Liverpool*, vol. v. p. 164) it will be seen that, taking three principal regions into consideration, the Arctic marine flora consists of 259 species belonging to 111 genera, the West Indian region possesses 788 species and 150 genera, the Australian 1132 species in 255 genera, and that nevertheless only 17 genera and 5 species of Rhodophyceæ, 6 genera and 1 species of Phæophyceæ, 5 genera and 6 species of Chlorophyceæ, and 4 genera and no species of Protophyceæ are common to all.

The structure, life-history, and classification of the lower algæ (both fresh-water and marine) having been dealt with in the article Algæ (q.v.), there is left for treatment the two higher groups—viz. Phæophyceæ and Rhodophyceæ. It will be most in accordance with the aim of the present article to sketch very briefly the main lines of classification, and to select a few typical examples for more detailed notice.

The Phæophyceæ include all the olive-brown seaweeds found on our shores, and are subdivided according to their methods of reproduction into three chief series—viz. (*a*) the Phæosporeæ, represented by such forms as Ectocarpus, Cutleria, Sphacelaria, and the giants among seaweeds, Laminaria, Macrocystis, and Lessonia; (*b*) the Fucaceæ—e.g. Fucus, Ascophyllum, Pelvetia, &c.; and (*c*) the Dictyotaceæ—e.g. Dictyota and Padina. The members of the Phæosporeæ have a most varied vegetative form. Many are filamentous and branched, such as Ectocarpus and Sphacelaria, some are tubular and unbranched, as Asperococcus and Scytosiphon, or tubular and branched—Chordaria. Others are ribbon-shaped—e.g. Cutleria; not a few are membranous and encrusting—e.g. Ralfsia; whilst Laminaria forms large expanded leathery-stalked fronds. In histological differentiation several types may be distinguished. In Ectocarpus the fronds consist of branched filaments of cylindrical cells, whilst in other genera the fronds are composed of elongated central cells surrounded by smaller cortical cells. In the Laminariaceæ the medullary portion of the thallus contains elongated branched tubular cells which show a marked resemblance to the sieve tubes of Phanerogams, whilst the small cortical cells exhibit that intercommunication of protoplasm which is of so great physiological importance in the higher plants.

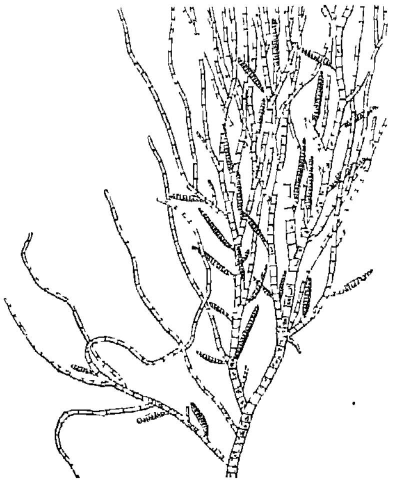

Fig. 1.—Ectocarpus confervoides:
A portion of the thallus with multilocular sporangia (× 10).

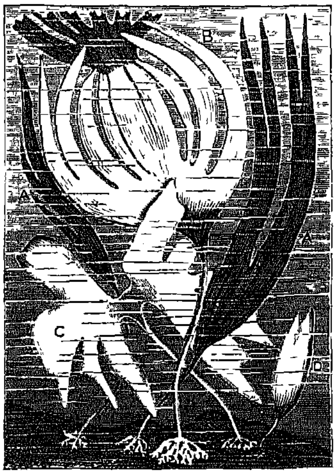

Fig. 2.—Laminariaceæ:
A, *Laminaria digitata*, var. stenophylla; B, C, *L. digitata*, var. cloustoni; D, young form of B (all much reduced). (After Luerssen.)

Both sexual and asexual methods of reproduction are known to occur, though not as yet in all genera. Vegetative propagation by gemmæ is also not uncommon. The asexual reproductive organs are in the form of unilocular sporangia, the contents of which are transformed into zoospores, small motile cells furnished with two flagella each, and capable after a period of activity of longer or shorter duration of settling down and forming new plants. The sporangia either are developed externally on the thallus or are the terminal cells of short branches. They are frequently collected in groups (*sori*), and are accompanied by sterile filaments. The sexual organs are multilocular sporangia (*gametangia*), of diverse form, each loculus giving rise to a single motile cell somewhat like a zoospore. These cells conjugate in pairs, the product (*zygote*) behaving in a precisely similar manner to the zoospore. Although in most of the Phæosporeæ the zoogametes are morphologically indistinguishable, interesting gradations may be observed in some genera where the zoogametes are differentiated into male and female cells. Cutleria is especially interesting in this respect, as the female gametes are much larger than the male gametes, and come to rest before conjugation with the still motile male cell.

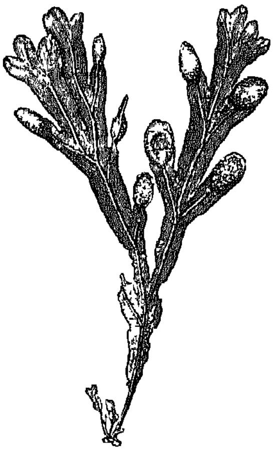

Fig. 3.—Fucus platycarpus:
A portion of the thallus showing receptacles (× ¼). (After Thuret.)

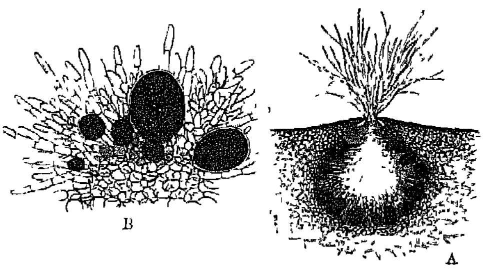

Fig. 4.—Fucus platycarpus:
A, vertical section through a conceptacle; B, portion of the wall of a conceptacle, showing oogonia in various stages of development, and antheridia. (A, × 20; B, × 150.) (After Thuret.)

The Fucaceæ are characterised by having distinctly differentiated sexual organs with non-motile ova and motile fertilising cells. The ova are formed within the swollen cells (*oogonia*) which arise from the wall of flask-shaped cavities (*conceptacles*), and are accompanied by unbranched hairs. The fertilising cells, antherozoids or sperms, are produced in ovoid terminal cells of branched hairs (*antheridia*), which likewise arise from the walls of similar conceptacles. In *Fucus platycarpus* both ova and sperms are formed in the same conceptacle; in most Fucaceæ, however, they are formed on different plants. Asexual multiplication is unknown. The group includes such well-known genera as Fucus, Halidrys, and Pelvetia, with branched leathery fronds, the tips of whose branches become transformed into receptacles for the reproductive organs, and Himanthalia, with a button-shaped thallus, from which arise the long strap-shaped reproductive branches characteristic of that genus.

The Dictyotaceæ are an aberrant group of Phæophyceæ with distinct affinities to the Rhodophyceæ. They resemble that group in having non-motile spores produced in fours in sporangia which are clustered in sori over the surface of the frond (Dictyota) or along the midrib. The sexual organs are in the form of antheridia and oogonia. The male organs produce non-motile fertilising cells resembling the pollinoids of the Rhodophyceæ, though Johnson (*Jour. Linn. Soc. Bot.*, vol. xxvii. p. 467) considers that possibly the pollinoids of Dictyopteris may be ciliated like those of Cutleria. The oogonia are arranged in sori, each containing one ovum. In both Fucaceæ and Dictyotaceæ fertilisation is external.

The Rhodophyceæ (*Florideæ*) form a very large assemblage of most varied vegetative form, and every possible shade of red from a purple black to brilliant pink. The root may be a branched mass, a plate, or a disc attached to mud, other algæ, or rock, whilst the fronds are filamentous, membranous, crustaceous, or calcareous. The asexual organs consist of sporangia whose entire contents in some genera escape as a single non-motile spore. In the majority, however, each sporangium contains four non-motile spores. The sporangia are solitary or grouped in sori, and often sunk in the tissue of the frond or in special branches. The sexual organs are antheridia and procarpia. The antheridia are generally modified terminal branches or special areas in the thallus (of the more succulent forms), from which are derived short rod-like fertilising cells, here called pollinoids. The female organ is a procarp, whose structure varies in complexity in the different orders of Rhodophyceæ. In the simplest condition it recalls the female organ of Coleochæte, and consists of a rounded cell with a long filamentous apical portion, the *trichogyne*. In higher members of the series the trichogyne is separated from that portion of the procarp from which the products of fertilisation (*carpospores*) are derived by one or more intermediate cells, the *trichophore*, and the basal part itself may become multicellular, all or only some of the cells of which produce the products of fertilisation. Fertilisation is effected by fusion of a pollinoid with the trichogyne, the immediate result being the formation of a cluster of cells, the carpospores, derived from the fertile cells of the base. These carpospores may form a mulberry-like mass (Nemalion), or be enclosed by a loose involucre of filaments (Griffithsia), or by an ovoid capsular investment with a terminal pore (Polysiphonia). In others again the collection of carpospores (cystocarp) is completely enclosed within a thick-walled spherical sac (Plocamium), or may be sunk in the tissue of the frond (Dumontia). The Rhodophyceæ embrace a large number of orders, the representatives of several of which form well-known objects of interest on the seashore. The best known of these perhaps are Carrageen (*Chondrus crispus*), Dulse (*Rhodymenia palmata*), and Laver (*Porphyra laciniata*). The genera Callithamnion, Delesseria, Nitophyllum, Plocamium, and Odonthalia are well known to collectors for the beauty of their fronds. In concluding this article it may be of interest to point out that the vast collection of feathery plant-like forms, popularly classed as 'seaweeds' by seaside visitors and sold as such after being fancifully tinted, are in no respect related to the forms we have been considering, but really belong to the zoophyte division (Hydrozoa) of the animal kingdom.

Sea-wolf. See WOLF-FISH.

Sebastian, king of Portugal (q.v.), a grandson of the Emperor Charles V., perished at the fight of Alcazar in Algeria, warring against the Moors, on 4th August 1578. Soon after the battle doubt was thrown upon his death, and impostors, pretending to be the chivalrous young king, began to crop up —first (in 1584) an adventurer, the son of a poor Portuguese potter, who was nicknamed, half in derision, half in raillery, the King of Penamacor; then came Matheus Alvares, a sort of brigand-insurgent; then in 1594 a Spanish cook of Madrigal in Castile. None of these people were taken seriously. A fourth impostor found more credence, one Marco Tullio Catizzone, a Calabrian, who first made his pretensions known at Venice in 1598. He was hanged at San Lucar in Spain in September 1603. The strongest support of these successive impostors was the undying belief of the common people of Portugal that their popular hero, Sebastian, would some day reappear. The belief grew particularly strong in 1807-8 during the French occupation of Portugal. And even so late as 1838 it was used as a rallying-cry by a party of insurrectionists amongst the Portuguese Brazilians. See M. D'Antas, *Les faux Don Sébastien* (1866).

Sebastian, St, a martyr of the early church, was a native of Narbonne. Under Diocletian he became a captain of the prætorian guard, and secretly a Christian. It coming to the ears of Diocletian how Sebastian personally encouraged those who were being led out to death for being Christians, the emperor had his captain tied to a stake and shot to death by archers. But they did not wholly kill him; a pious woman, Irene by name, took him away, and tended his wounds. As soon as he was recovered Sebastian boldly faced the tyrant, and upbraided him for his cruelty. Diocletian then ordered him to be beaten to death (288) with rods. He is a protector against plague and pestilence, and is specially honoured on 20th January. His first martyrdom—a young and handsome soldier bristling with arrows—was a favourite subject for the Italian religious painters, as Mantegna, Veronese, and Domenichino.

Sebastiani, François Horace Bastien, Count, marshal of France, was born November 10, 1772, at Porta d'Ampugnano, a village near Bastia, in Corsica. Entering the French army in 1789, he became one of Napoleon's most devoted partisans, and advanced rapidly. He fought at Marengo, executed some important diplomatic service in Turkey in 1802-3, after which he became general of brigade, and was wounded at Austerlitz. In 1806 he was again deputed to Turkey, this time to break the alliance of the Porte with Russia and England. His mission was successful, and Turkey declared war upon the allies. Thereupon the English fleet forced a passage through the Dardanelles, and cast anchor before Constantinople. Sebastiani, however, speedily put the coast batteries in a state fit for action, and got several small gunboats afloat. But the deposition of the sultan and the treaty of Tilsit put an end to the French intrigues in Turkey, and Sebastiani was recalled (June 1807). He subsequently commanded the fourth French army corps in Spain, and distinguished himself in the Russian campaign of 1812 and at Leipzig. On the exile of Napoleon to Elba he gave in his adherence to the Bourbon government, but joined his old master on his return. After the revolution of 1830 he held for brief periods the portfolios of naval and foreign affairs, and the embassies to Naples and London, but was more distinguished for his elegance and graceful demeanour in the Parisian salons than as a politician or administrator. He was made a marshal of France in 1840, and died at Paris, July 20, 1851.

Sebastiano del Piombo, Italian painter, whose family name was Luciani, and who got his nickname 'Of the Seal' (*Piombo*) because at the accession of his patron, Giulio de' Medici, as pope (Clement VII.) in 1523 he was given the office of sealer of papal briefs. He was born at Venice in 1485, and learned the art of painting from Giovanni Bellini and Giorgione. After painting a St Chrysostom for the church of that saint in Venice, Sebastiano was taken to Rome by Agostino Chigi (q.v.) about 1512. He helped to decorate Chigi's palace of Farnesina with frescoes illustrating classical mythology, and by his excellence as a colourist won the esteem and friendship of Michelangelo. The two seem then to have worked in conjunction, Sebastiano carrying out in colour designs and drawings made by Michelangelo. Amongst the fruits of this artistic partnership three pictures at least are of the highest rank—viz. 'The Raising of Lazarus' (in the London National Gallery), and a couple of scenes from the last days of Christ (in the church of St Peter in Montorio at Rome). Sebastiano, who possessed no great powers of invention, excelled also as a portrait-painter. The best specimens of his skill in this particular line embrace portraits of Pope Clement VII., Andrea Doria, two members of the Colonna family, Sebastiano himself, Cardinal Pole, and a lady as St Agatha. An indolent man and a dilatory, Sebastiano did little painting after his appointment as papal seal-keeper; yet he invented a method of painting on slate and stone. He died at Rome in 1547.

Sebastopol, or Sevastopol, a Russian seaport and fortress, is situated near the south-west extremity of the Crimea, on the southern side of one of the finest natural harbours in the world, 4½ miles long from east to west and ½ mile across. The place is celebrated for the long siege of the allies during the Crimean war of 1854-55. The town and harbour were defended by several forts and batteries, mounted by 700 guns in all, some of heavy calibre. The forts were of immense strength, built of limestone faced with granite, on which artillery was found to make but little impression. On the land side, with the exception of a slight loopholed wall extending partially round the western side, the town, previous to the siege, was entirely undefended; but the earthworks and fortifications then successively extemporised by the genius of General Todleben kept the armies of France and England at bay for eleven months, from October 1854 to September 1855. The place sustained repeated bombardments until the capture of the Malakoff and Redan works, on September 8, 1855, at length forced the Russians to evacuate the lines and retire to the north side. The town was completely ruined; the docks and forts still standing were blown up by French and English engineers, and by the treaty of Paris (1856) were not to be restored; but the restrictions were removed by the abrogation of the neutrality of the Black Sea by the Conference of London (1871). Since the siege the town has been in great part rebuilt, but at first grew slowly. However, since 1885 the Russian government have been actively restoring the fortifications and reconstructing the docks, it having been decided that Sebastopol was to be reserved entirely for the imperial navy, and a new commercial port to be built on a bay 2 miles south-west of the town or else at Theodosia. The trade fluctuates greatly, the imports between £134,660 (1890)—chiefly for cotton and coal—and £653,210 (1887), and the exports between £1,315,600 (1890) and £3,072,560 (1889), all for grain. Pop. (1890) 29,000, exclusive of a garrison of 12,000. Sebastopol was founded on the site of a Tartar village immediately after the Russian conquest of the

Crimea in 1783, under the orders of the Empress Catharine II. The promontory on which it stands was originally colonised by Greeks from Heraclea, in Asia Minor, and became known as the Heracleotic Chersonese.

See CRIMEAN WAR; Kinglake's *Invasion of the Crimea*, Hamley's *War in the Crimea* (1891), Todleben's *Vertheidigung von Sebastopol* (4 vols. Berlin, 1864-72), and Leo Tolstoi's vivid description of the siege in *Sebastopol* (Eng. trans. 1890).

Sebenico (Slav. *Sibenik*), a picturesque town of Austrian Dalmatia, stands on a landlocked bay of the Adriatic, 43 miles by a branch-line of railway NW. of Spalato. The chief ornament of the place is its cathedral, built all of stone, in 1430–1555. The style is Italian Gothic. Three forts and walls on the land side defend the city. Fishing is carried on, and there is some trade in wine and olive-oil. Pop. 6858. It was a favourite place of residence of the kings of Croatia, was made the seat of a bishopric in 1298, and repulsed a siege by the Turks in 1647. See Jackson's *Dalmatia* (vol. i. 1887).

Sebillot, PAUL, an eminent French folklorist, was born at Matignon, in the department of Côtes-du-Nord, February 6, 1843. After his studies at the communal college of Dinan, and a course of law at Rennes, he came to Paris to become a notary, but soon abandoned the pen for the pencil. The pursuit of his art carried him to Saint-Brieuc and Pont-Aven, and many an out-of-the-way corner of Brittany, and opened up to him stores of old-world lore in which he was to find the main interest of his life. From 1870 to 1883 he exhibited in the Salon as many as twenty pictures, but he gradually abandoned art for folklore, and made his name widely known by a series of admirable books. He succeeded to Henri Martin's seat in the Commission for Megalithic Monuments, became *chef du cabinet* at the ministry of Public Works, and was nominated Chevalier of the Legion of Honour in July 1889. He edited the *Revue des Traditions Populaires* from its foundation (1885), and acted as general secretary to the Congrès International des Traditions Populaires at Paris in 1889.

Among his works are *Contes Populaires de la Haute-Bretagne* (3 series, 1880, 1881, 1882); *Littérature Orale de la Haute-Bretagne* (1881); *Traditions et Superstitions de la Haute-Bretagne* (2 vols. 1882); *Contes de Terre et de Mer* (1883); *Gargantua dans les Traditions Populaires* (1883); *Le Blason Populaire de la France* (with H. Gaidoz, 1884); *Contes des Provinces de France* (1884); *Coutumes Populaires de la Haute-Bretagne* (1885); *Légendes, Croyances, et Superstitions de la Mer* (2 vols. 1886, 1887); besides Bibliographies of the folklore of Brittany, Alsace, Poitou, Auvergne, and France d'Outremer, and a host of papers on Breton language and folklore.

Secale. See RYE.

Secant. See TRIGONOMETRY.

Secchi, ANGELO, astronomer, was born at Reggio, 29th June 1818, and trained as a Jesuit, became professor of Physics at Washington, United States, and in 1850 at the Collegio Romano, and director of the Roman observatory, where he laboured till his death, 26th February 1878. His chief discoveries were in the region of spectrum analysis and solar physics; and, besides some 300 papers, he published in French *Le Soleil* (1870), and in Italian *L' Unita delle Forze Fisiche* (1869) and *Le Stelle* (1877).

Secession. See UNITED PRESBYTERIANS; also UNITED STATES.

Seckendorff, VEIT LUDWIG VON, statesman and theologian (1626–92), studied at Strasburg, and served successively the princes of Saxony and Brandenburg, being chancellor of the university of Halle at his death. He is best known for a Latin compendium of church history (1664), and a work, *De Lutheranismo* (1688), in reply to Maimbourg.—His nephew, FRIEDRICH HEINRICH (1673-1763), was distinguished as a field-marshal and diplomatist in the Austrian service, and was made a Count of the Empire.

Secker, THOMAS, Archbishop of Canterbury (1758-68), was born at Sibthorpe, Nottinghamshire, in 1693, the son of a Dissenter of independent means, who wished him to enter the ministry of his own communion. In 1716, however, the son turned to medicine, which he studied at London and Paris, ultimately taking his doctorate in physic at Leyden in 1721. Meanwhile, urged by his old schoolfellow, Joseph Butler, he had decided to take Anglican orders; in 1722 he graduated B.A. at Oxford, and in that and the following year he was ordained deacon and priest. His preferments were Houghton-le-Spring (1724), Ryton and a prebend at Durham (1727), chaplain to the king (1732), St James's, London (1733), Bishop of Bristol (1735), of Oxford (1737), Dean of St Paul's, for which he resigned the living of St James's (1750), and the primacy (1758). He was a wise, kindly, hard-working bishop, and a notable preacher in his day. He died 3d August 1768. See the *Review of his Life*, by Beilby Porteous (5th ed. 1797; originally prefixed to a posthumous edition of his sermons, &c. 1770).

Second is the sixtieth part of a minute, whether of time or of angular magnitude; formerly seconds having been distinguished as *minutæ secundæ*, from minutes or *minutæ primæ*. See CIRCLE, DEGREE, DAY.

Second Advent. See ADVENTISTS, MILLENNIUM.

Secondary, in Geology. See PETROGRAPHY, MESOZOIC.

Second'ing is an arrangement by which officers of the British army, when extra-regimentally employed, become supernumeraries in their regiments, and have their places filled by others, so that the service may not suffer. Thus, a captain appointed adjutant of yeomanry, militia, or volunteers is placed upon the seconded list for the five years during which his appointment lasts. His place in the regiment is filled up, but his name (in italics) remains in its usual place in the *Army List*, his promotion goes on, and he is brought back at the end of his employment as soon as a vacancy occurs in his proper rank.

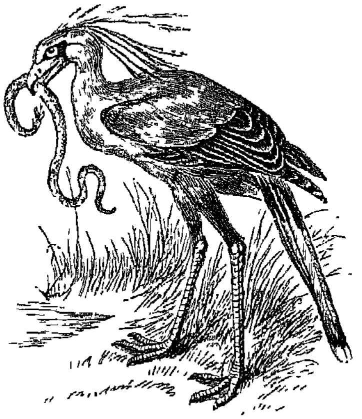
Second-sight, a gift of prophetic vision, long supposed in the Scottish Highlands and elsewhere to belong to particular persons. The most common form it took was to see the *wraith, fetch*, or shadowy second self of some person soon to die, often wrapped in a shroud, or attended with some other of the special circumstances of death or burial. Of course the prophetic character may easily enough have been a mere additional assumption, the time of occurrence of distant events being apt to be confused with the time of hearing of them. In the popular mind everywhere the mystery of death, and the instinctive human longing to believe in a continuity of conscious spiritual life and sympathy, have generated a belief in the probability of an appearance coinciding with, or soon succeeding, the death of an individual; and from this the step is easy to a belief in the possibility of similar appearances before death, in order to foreshadow or forewarn. For, if the appearance be admitted as a probability, it is not difficult to take a further step and attribute to it the function. For what more natural than to suppose that, just as the affection for a dead friend survives the separation of the grave, so the affections of the disembodied spirit or apparitional ghost-soul should continue to cling to the persons loved on earth, and that he should seek by every possible means to give them forewarnings of things soon to happen? And what agents more natural than those gifted souls that stand between the living and the dead, who have attained clearness of spiritual vision by rising above the bondage of sense, through lonely meditation and inner communion with things unseen? Such are the seers to whom the gift of second-sight was once attributed in the Highlands; and we find, as was to be expected, that most often they were reputed men of severe and virtuous life, who would gladly have lost their faculty if they could, and indeed were often sorely troubled in their minds as to whether it was not something that had come from the devil and not from God. In Aubrey's account we read of one who besought the presbytery to pray for him that he should be relieved from this burden, and how after special supplication and confession it was taken from him. Among the Covenanters too the gift of special foresight and prophecy was one vouchsafed to men like Peden, eminent for holiness and spiritual elevation. The gift seems not to have descended by succession, although this is stated to have been the case in Skye before the gospel reached it, and there was long a persistent belief that it belonged to the seventh son of a seventh son; according to some it appears in special cases to have been capable of being communicated from one person to another. Martin in his *Description of the Western Isles of Scotland* (1703) gives a full account of the second-sight, with a classification of the special visions usually seen, which is conveniently summarised in the seventh chapter of Defoe's well-known *Life and Adventures* of Duncan Campbell (*c.* 1680–1730), the deaf and dumb soothsayer, who inherited the faculty from his Lapland mother. With regard to the difficult question of the determination of the time between the sight and the fulfilment, we read here that if an object was seen early in the morning the event would be accomplished a few hours afterwards; if at noon, the same day; and if at night, the accomplishment would take place weeks, months, and sometimes years afterwards, according to the time of night the vision was beheld. The appearance of a shroud was an infallible prognostic of death, and the nearness or remoteness of the event was judged by the amount of the body that was covered by the ghastly sheet; if it was not seen above the middle, a delay of a twelvemonth might be hoped for; but if it ascended high towards the head, the mortal hour was close at hand. The reader will remember the splendid artistic use made of an analogous notion to this by Rossetti in *The King's Tragedy*. The vision makes such a lively impression upon the seers, continues Martin, that they neither see nor think of anything else except the vision, as long as it continues; the eyelids of the seer are rigidly fixed, and the eyes continue staring until the object vanishes. Sir Walter Scott has put the second-sight to fine use in *Waverley*, *The Legend of Montrose*, and elsewhere.

The gradation of symbolical appearances we have mentioned strikes the imagination and gives something like a system to the supernatural phenomena. But if we turn to the cases related we find no such regular order and exactness. The evidence is vague and confused, and the incidents are often of the most trivial character, the revelations, apparently mere subjective hallucinations, commonly made to poor illiterate men, predisposed from their conditions of life to melancholy and superstition. Moreover, one standing weakness is that such predictions may force their own fulfilment, and the indefiniteness of the time provides a convenient loophole of escape for the conscience. As we see in the popular notions about dreams, there is a besetting snare of a tendency unconsciously to antedate the later impression and to read back details into the dream. Even contradictory dreams are forced to the required interpretation on principles of implied symbolism or even of mere conventional and completely irrational explanation; and similarly we find unrecognised apparitions capable of symbolic explanation, as a black dog appearing before a death, phantasmal lights, and the like, as well as weeping, the screech of the *banshee*, &c., in the region of sounds. Again, coincidences, really due to pure accident, account for much; and still more the invariable leaning of the primitive mind to false analogies and to confound the *post hoc* with the *propter hoc*. The savage and the enthusiast alike think in the same vicious circle; what he believes he therefore sees, and what he sees he therefore believes.

Stories of second-sight meet us also in the actual world of history. We find it in the story of Wallace and Bruce; again in the famous vision that Thomas the Rhymer had of the death of Alexander III. at Kinghorn; associated with the tragic fate of James I.; and in the unheeded warning given to the Scottish nobles before going to find their fate at Flodden. A Scottish seer is said to have foretold the unhappy career of Charles I., and another the violent death of Villiers, Duke of Buckingham. In 1652 Sir George Mackenzie, afterwards Lord Tarbat, wrote a minute account of its manifestations, addressed to the celebrated Robert Boyle, which is published in the correspondence of Samuel Pepys. Aubrey throughout life had strong interest in the superstition, and has recorded not a few examples. Next came Martin's copious description, then the Rev. John Fraser's *Authentic Instances* (1707), and in 1763 the ambitious but poor and credulous *Treatise on the Second Sight* by Theophilus Insulanus. A fresh revival of interest in the subject took place after the publication of Dr Johnson's memorable *Journey to the Hebrides* (1775). Johnson was naturally superstitious, and would willingly have believed in the possibility of messages from the other world. But his love of truth was too strong to be satisfied with the evidence, and he confessed that he never could 'advance his curiosity to conviction, but came away at last only willing to believe.' On one occasion Boswell tells us he laid down a sound canon for such questions, incapable to be shaken: 'We could have no certainty of the truth of supernatural appearances unless something was told us which we could not know by ordinary means, or something done which could not be done but by supernatural power; that Pharaoh, in reason and justice, required such evidence from Moses; nay, that our Saviour said: "If I had not done among them the works which none other man did, they had not had sin."' As we have seen, spectral sights may be caused by dreams, and every night so many are dreamed that some must come true; morbid conditions of mind or body may account for many more; not to speak of accidental optical illusions, or the workings of an abnormally vivid imagination. And again, from the other side, we may say that it is hardly a compliment to the idea of a divine providence to suppose that special miracles are wrought to announce the marriage or death of a Highland peasant, the wreck of a boat, the winner of a race, or the arrival of a stranger in a remote island of the Hebrides. Nothing wiser on this question generally has been written than Mrs Henry Sidgwick's paper, 'On the Evidence for Premonitions,' in the *Proceedings of the Society for Psychical Research* for December 1888. She defines premonitions as predictions, foreshadowings, or warnings of coming events, which afford, if believed, a knowledge of the future greater than that which human beings could obtain by exercising their faculties on the facts before them; and her conclusion is that the evidence at present collected does not seem sufficient to warrant a conclusion in favour of these. The whole of the first-hand cases up till that time before the Psychical Society amounted to 240, about 66 per cent. of these being dreams, thus falling far short both in quantity and quality of the evidence for *telepathy*. Setting aside the two-thirds dreams, she classifies the remaining third as follows: (1) Visual hallucinations—persons or objects seen when nothing was really there; (2) auditory hallucinations—voices or other sounds heard when, according to the belief of the percipient, there was no real natural sound; (3) verbal predictions, as by fortune tellers; (4) non-externalised impressions of various kinds—namely, ideas of more or less definiteness, mental visions, mental voices, and motor impulses. See the articles ANIMISM, APPARITIONS, DIVINATION, DREAMS, and MAGIC.

Secret, DISCIPLINE OF THE. See DISCIPLINA ARCANI.

Secretary-bird, also called SECRETARY-FALCON, or SERPENT-EATER (*Serpentarius reptilivorus*), a genus of birds of prey, which has been variously placed by naturalists among the Falconidæ and the Vulturidæ, but must certainly be constituted into a distinct family, Gypogeranidæ. The legs are very long, as in the Grallæ, to some members of which group it shows other points of affinity. The tibiæ are completely feathered, but the tarsi and toes are destitute of feathers. The tarsi are covered in front with long, large scales. The toes are armed with sharp claws; but they are short, and the feet are not formed for grasping. The hind-toe is very short. The neck is much longer and the whole form of the bird more slender than in the Falconidæ. The tail is very long. The best-known species is an inhabitant of the arid plains of South Africa.



Secretary-bird (*Serpentarius reptilivorus*).

It is about three feet in length; the plumage bluish gray. It has an occipital crest of feathers without barbs at the base, which can be raised or depressed at pleasure, and the name 'Secretary' was given to it by the colonists at the Cape of Good Hope from their fancied resemblance to pens stuck behind the ear. It feeds chiefly on reptiles of all kinds, which it devours in great numbers, and is so highly valued on account of the constant war which it wages against serpents that a fine is inflicted in the Cape Colony for shooting it. It fearlessly attacks the most venomous serpents, stunning them with blows of its wing, or seizing and carrying them into the air to such a height that they are killed by the fall. It uses its feet also to overpower its prey, striking violent blows with them. Small serpents are swallowed entire; the larger ones are torn to pieces. The secretary-bird is most frequently seen in pairs, or solitary. It is tamed as a protector of poultry-yards, but if not sufficiently fed is apt to help itself to a chicken or duckling. An attempt has been made to introduce this bird into Martinique in order to reduce the number of venomous serpents in that island.

Secretary of State, an ancient and important office in the government of England. The oldest record of its existence is in the reign of Henry III., when John Maunsell is described as 'secretarius noster.' Prior to the Restoration the holder of this office was generally styled the 'king's chief (or 'principal') secretary;' he had the custody of the king's signet, and discharged his duties with the assistance of four clerks. Two secretaries are said to have been first appointed towards the close of the reign of Henry VIII. The office, always one of influence, gradually grew in importance. On the Union of 1707 Anne added a third secretary of state for Scotland, which office, however, was soon done away with. In the reign of George III. there were at first but two secretaries; for a time there was a third for America, but his office was abolished by statute in 1782. While the secretaries were two in number both equally directed home affairs; to the one were committed the foreign affairs of the northern, to the other of the southern department. Irish affairs belonged to the province of the elder secretary.

There are now five principal secretaries of state, who are respectively appointed for home affairs, foreign affairs, war, the colonies, and India. They are all appointed by the sovereign by delivery of the seals of office, followed by the issue of a patent under the great seal, and they are always members of the Privy-council and of the cabinet. Though each has his own department, he is considered capable of discharging the duties of the others; a member of the House of Commons if removed from one secretaryship to another does not thereby vacate his seat. Not more than four secretaries or under-secretaries of state may sit at one time in the House of Commons.

The Secretary of State for the Home Department has the charge of the maintenance of the internal peace of the United Kingdom, the security of the laws, and the administration of justice so far as the royal prerogative is involved in it. He provides for the suppression of riots. He has the ultimate supervision of all that relates to prisons and criminals; and numerous statutory powers have been given him regarding police, sanitary matters, the regulation of labour, &c. He is responsible for the exercise of the prerogative of mercy; application for pardon or commutation of sentence forms no small part of the work imposed on the Home Secretary. All patents, licenses, dispensations, charters of incorporation, commissions of the peace and of inquiry pass through his office. He recommends persons to the sovereign for civil knighthood, and is empowered to grant certificates of Naturalisation (q.v.) to foreigners. He is the organ of communication between the cabinet and the viceregal government of Ireland, for which he is responsible, and is informed of and advises all the graver measures adopted in that country. His patronage is very considerable, including the nomination to a large number of judicial offices. Among his powers is that of examining and committing for trial persons charged with offences against the state, a function which, though its legality has been called in question, has been often exercised.

The Secretary of State for Foreign Affairs is the responsible adviser of the crown in all communications between the government and foreign powers. He negotiates treaties, either directly with the foreign ministers resident in the country, or through the British ministers abroad. It is his duty to inquire into the complaints of British subjects residing in foreign countries, to afford them protection, and to demand redress for their grievances. The Foreign Secretary recommends to the sovereign all ambassadors, ministers, and consuls to represent this country abroad. He grants Passports (q.v.) to British subjects travelling abroad.

The Secretary for the Colonial Department has the supervision of the laws and customs of the colonies and dependencies (except India), watches over their interests, apportions the imperial troops necessary for their defence or police, appoints governors, and sanctions or disallows laws reserved for his consideration by colonial governors. The responsibilities of the colonial office in regard to the greater colonies have been much decreased by the extension of responsible government (see COLONY).

Each of these secretaries of state is assisted by two under-secretaries of state—one permanent, while the other is a political officer dependent on the administration in power.

The Secretary of State for India, whose office dates from the abolition in 1858 of the double government of India by the Court of East India Directors and Board of Control, has the same control over the government of India which was formerly exercised by these bodies, and countersigns all warrants and orders under the sign-manual relating to India. He is assisted by an under-secretary, who is also a member of the legislature and loses office with the cabinet, and by a permanent under-secretary and assistant-secretary, as also by a council of fifteen members, over whom he presides. Every order sent to India must be signed by the secretary, and all despatches from governments and presidencies in India must be addressed to the secretary.

The Secretary of State for War has the superintendence of all matters connected with the army, assisted by the commander-in-chief, and is responsible for the amount of the military establishment. He prepares for the royal signature and countersigns commissions in the army, and recommends to the sovereign for the order of Knighthood of the Bath. Down to the Crimean war there was also a Secretary-at-war, a high officer of the ministry, who had the control of the financial arrangements of the army, and was the responsible medium for parliamentary supervision in military affairs. He was quite independent of the Secretary of State and of the military authorities.

The Chief-secretary to the Lord-lieutenant of Ireland and the Secretary for Scotland do not rank as secretaries of state, though they may be members of the cabinet. For a full account of the secretarial departments, see Todd's *Parliamentary Government in England* (2d ed. 1889).

In the cabinet of the United States there is one Secretary of State, who is specially charged with foreign affairs.

Secretary of the Navy, now called the Secretary to the Admiralty, is the conventional title of the parliamentary secretary to the Board of Admiralty. This post is conferred on a ministerial supporter in the House of Commons, in which when the First Lord of the Admiralty is a peer he is the exponent of naval policy; and he is also mainly responsible for the financial administration of the service. He changes of course with the ministry, of which he is a subordinate member, and receives a salary of £2000 a year. There is also a permanent secretary, generally a naval officer, who holds office for life, and receives £1700 a year. He is responsible for the discipline of the Admiralty Office. This appointment is of long standing, and was held by the celebrated Samuel Pepys.

Secret Chambers were mostly of post-Reformation construction, designed as 'priest's holes,' or hiding-places for 'trafficking mass-priests,' in the days when to say mass was either high-treason or felony. They might also, of course, conceal Jacobite or other conspirators; and that of Danby Hall, the seat of the Scropes, was found, on its rediscovery about 1800, to contain arms and saddlery for forty or fifty troopers, stored up, it would seem, against some intended rising. Brother Nicholas Owen, S.J., *alias* 'Little John,' who with Father Garnet (q.v.) was arrested at Hindlip Hall, and who is termed 'that useful cunning joiner of those times,' was a chief contriver of these secret chambers, and after his capture 'was divers times hung upon a Topcliff rack in the Tower of London to compel him to betray the hiding-places he had made up and down the land.' They were oftenest formed in the thickness of a wall, and the entrance to them might be through a panel, behind a hinged picture, beneath a hearth-stone, up a chimney, &c. About a century since at Irnham Hall, Lincolnshire, it was noticed that one of the chimneys of a cluster was unblackened, and it proved to be really a shaft to give light and air to a priest's hole, the entrance to which was gained by removing a single step between two servants' bedrooms. You then come to a panel, with a very small iron tube let into it, through which any message could be conveyed to the occupant. This panel removed, a ladder of four steps leads down to the secret chamber, which is 8 feet long, 5 broad, and just high enough to stand upright in. Another at Ingatestone Hall, the old seat of the Petres, is 14 feet long and 10 high, but only 2 wide; this contains an old chest for vestments. How cunningly these chambers were contrived may be seen in the fact that at Hindlip the minutest search was made ten whole days in vain, till Garnet came forth himself, forced by want of fresh air, not of food, for marmalade and other sweetmeats were lying by him, and 'broths and warm drinks had been passed to him by a reed through a little hole in a chimney that backed another chimney into a gentlewoman's chamber.' Smugglers during the 18th century had sometimes secret chambers of a sort, for the storage of 'run' goods, at farm-houses a few miles inland; nay, so late as 1860 one such was used for illicit malting in a Suffolk village, till the excise officer detected its whereabouts by pouring water over the floor above. But for the last *historical* instance of their use we must look abroad, to Nantes, where in 1832 the Duchess de Berri (q.v.), a corpulent lady, was, with two gentlemen, roasted out of a secret chamber at the back of a fireplace, after sixteen hours' patient endurance.

The following is a list of some of the best-known secret chambers, arranged under counties in alphabetical order, with the date sometimes of the erection of the mansion (not necessarily, of course, of the priest's hole) or of its demolition, and with the names of traditional occupants: *Berkshire*, Lyford; Milton, near Abingdon; Watcomb. *Bucks*, Dinton (regicide Mayne). *Berwick*, Bemersyde. *Cambridge*, Sawston. *Cheshire*, Bollington; Lyme Hall, near Disley. *Cornwall*, Bochym. *Cumberland*, Netherhall, near Maryport. *Derby*, Bradshaw Hall, near Chapel-en-le-Frith; Hallam. *Durham*, Bishop Middleham (in which a 'teetotaller drank himself to death with brandy,' Southey's *Commonplace Book*, 4th series, 354). *Essex*, Ingatestone (*temp.* Henry VIII.). *Forfar*, Glamis Castle (the Toad-headed Monster). *Gloucester*, Bourton-on-the-Water (demolished 1834). *Hants*, Hinton-Ampner; Mapledurham, Moyles Court (Lady Lisle's house); Titchborne. *Hereford*, Treago. *Herts*, Knebworth (1553, demolished 1811). *Lancashire*, Ashes, at Goosnargh; Borwick; Lowstock Hall, in Bolton parish (demolished 1816); Lydiate; Mains Hall, in Kirkham parish (Cardinal Allen); Speke Hall; Widnes House, near Warrington; Stonyhurst (in great tower). *Leicester*, Long Clawson. *Lincoln*, Irnham Hall (c. 1500); Kingerby Hall; Upton. *Middlesex*, Canonbury Tower, Islington; Cromwell House, Highgate; White Welles House. *Monmouth*, Raglan Castle. *Norfolk*, Oxburgh House. *Northants*, Burghley House; Harrowden. *Northumberland*, Netherwitton (Lord Lovat?); Wallington Hall. *Notts*, Worksop Manor (burned 1761). *Oxford*, Broughton Castle; Chastleton; Minster Lovel (Lord Lovel, Simnel's adherent, starved to death here, 1487, and skeleton found in 18th century?). *Pembroke*, Carew Castle (*temp.* Henry I.). *Shropshire*, Boscobel (Charles II.); Pitchford; Plowden; White Ladies (Charles II.). *Somerset*, Trent Manor House (Charles II.). *Stafford*, Moseley Hall (Charles II.). *Suffolk*, 'Ancient House,' Ipswich (1567; Charles II.?); Coldham Hall; Melford Hall. *Surrey*, Benton; Ham House, at Weybridge (1610, hiding-places shown to Evelyn by Duke of Norfolk); Sanderstead Court; Sutton Place, near Guildford (*temp.* Henry VIII.). *Sussex*, Ashbourne Place (Bishop Juxon); Cowdray (Lord Montague); Parham; Pax Hill, near Cuckfield (built by Andrew Boorde, q.v.); Slindon; Street Place; West Grinstead. *Warwick*, Congleton Court; Compton-Wyniates (*c.* 1520). *Wilts*, Heale House, near Amesbury (Charles II.; visited by Dr Johnson, 1783). *Worcester*, Armscott Manor House, near Shipston-on Stour (George Fox the Quaker); Birtsmorton Court (14th century; Sir John Oldcastle); Harborough Hall; Harvington; Hindlip Hall (eleven hiding-places, now demolished; see above); Little Malvern Court. *Yorkshire*, Abbey House, Whitby; Danby Hall, near Bedale; Dinsdale; the Grove, Leyburn; the 'New Building,' near Kirkby Knowle; Red House (Henry Slingsby).

See *Notes and Queries* for 1855-56 and 1879-85, Chambers's *Book of Days* (i. 433, 1869), and two articles in *Chambers's Journal* for Dec. 1883 and Oct. 1886.

Secretion is a vital process in which certain cells of the body form within themselves definite products, which accumulate and are usually discharged. The cells specialised for secreting are called glandular, and many are often united to form a Gland (q.v.). The definite products formed by the activity of the glandular cells are called secretions, this term being applied both to process and products. All the digestive juices, the silk of silkworms, the webs of spiders, the wax of bees, the nectar of flowers, and the like, are secretions. They are formed by the activity of the living matter from materials derived from the blood, or, when there is no blood, from the supplies of food which otherwise reach the glandular cells. They are discharged sometimes by a slow outpouring comparable to filtration through the free surface of the cell, sometimes by the more or less complete rupture of the cell. The process of secretion is usually periodic, intervals of quiescence alternating with those of activity. See GLANDS, PHYSIOLOGY, DIGESTION. For the secretion of plants, see VEGETABLE PHYSIOLOGY.

Secret Service Moneys, in the widest sense of the term, include all funds placed at the disposal of ministers of state, to be expended at their discretion without giving an account. In the 18th century large sums were paid for secret service out of the king's civil list; these moneys were used chiefly for the purpose of bribing members of parliament. In 1782 Burke carried his scheme of financial reform; the amount to be paid from the civil list was limited to £10,000, and ministers expending secret service money were required to make a declaration that they had done so in accordance with the intentions of parliament. In 1886 the matter was further considered, and an act was passed under which the payment authorised by the law relating to the civil list was discontinued. All moneys required for secret service are now included in the estimates; a sum of £35,000 has been voted on this account for some years past. The declarations required by Burke's Act are sufficiently stringent to prevent any gross abuse; there is no ground for the suggestion, still occasionally made, that secret service moneys are used in paying the election expenses of ministers. Almost all governments have some fund of which no public account is given; and all secret expenditure is naturally viewed with suspicion by the representatives of the taxpayers.

Secret Societies, in some form or other, have existed in all ages of the world's history, not only amongst nations with well-organised systems of social and public life, but also amongst races that have never advanced beyond the elementary stages of social organisation. Religion and politics are the departments of human activity in which such societies have most prevailed; though they have also been formed for judiciary, scientific, civil, social, and even criminal purposes.

In the ancient world many of the more influential religions had their Mysteries (q.v.), the ceremonies connected with which were generally performed in secret, and only in the presence of those who had been duly initiated. These inner and more secret groups of priests and initiated worshippers existed in association with the worship of Mithras in Persia, of Orpheus and Dionysus in Greece, at Eleusis and elsewhere, of Osiris and Serapis in Egypt, and of the Great Mother (Cybele) in Phrygia. The main objects which these exclusive coteries had before them were of course various: in some cases the intention was to render the sacredness and binding force of religion all the stronger over the hearts and imaginations of men; in others to preserve the 'holy things' from the profanations and familiarities of the vulgar throng; in others to enrich the temple or shrine; and in yet others the ruling motive seems to have been solely the wish to keep in a few hands the power that invariably attaches itself to the priestly office. The followers of Pythagoras formed what was in many respects a secret religious society, though philosophy and political doctrine took a foremost place in their teachings. The Druids are often represented as practising secret rites, handed down through certain of the priests; but upon this matter the evidence is shadowy in the extreme. Amongst the Jews there proceeded from out of the Pharisees the puritanical Essenes (Chasidim), who for the purpose of living a holier life formed themselves into what were virtually religious clubs, characterised by many features common to exclusive religious societies. The Essenes were the forerunners of the Jewish Cabbalists (see CABBALA), who professed a secret system of theology and philosophy associated with mystic practices, and of the Christian Gnostics, who formed exclusive sects based on initiation and esoteric teaching (see GNOSTICISM). The lineal successors of these last were the various mediæval sects of Cathari (q.v.), most of whom invested their teaching and their worship with many features of mystery. In the Roman Catholic Church the office of the Inquisition deserves to be called a secret society, and so does the order of the Jesuits, especially in respect of its methods; though in both cases the secrecy was due to political rather than to strictly religious causes. The Knights Templars (q.v.) towards the close of their history as a distinct order seem in several cases to have lapsed into the practice of secret rites and belief in certain secret doctrines. The Druses hold a peculiar place as the inheritors of a national religion which is jealously exclusive both in doctrine and ritual.

The Rosicrucians (q.v.) and the Freemasons (q.v.) are perhaps the best known of the secret societies that have cultivated something like social aims. The former had their origin in the 17th century, and directed their attention to the discovery of such things as the philosopher's stone and the elixir of life, to the exorcism of spirits, and such-like pursuits. Speculative Freemasonry does not go further back than the 18th century; its professed objects are philanthropic and moral. There are associations similar in character to it in Tahiti and others of the Pacific Islands, and amongst the Foulah and the Negroes of Sierra Leone and the adjacent parts of Africa. The celebrated *Vehmgerichte* (q.v.) or secret courts of Westphalia arose in a time of great public confusion, and made it their business to maintain that order and respect for the law which it should have been the concern of the emperor and his associates to have secured and preserved. There existed in Sicily from the 12th to the 18th century an organisation (the Beati Paoli) very similar to the *Vehmgerichte.* On the other hand, there have been numerous associations of a secret kind formed for criminal purposes, and for mutual assistance against and in defiance of the laws of the land; the Assassins in Persia and Syria, the Thugs in India, the Camorra, the Maffia, and the Decisi (*c.* 1815) in Italy, the Chauffeurs in France (who arose during the religious wars and were not suppressed until the Revolution), and the Garduna in Spain (formed after the wars against the Moors; suppressed in 1822) may be instanced.

The Illuminati (q.v.), the authors of a movement that grew up in Germany in the end of the 18th century, united political and religious ends, and may be said, summarily, to have aimed at realising the ideals of the French Revolution. The following century was wonderfully prolific in political secret societies. Italy was literally honeycombed with them during the years she was struggling for her independence; the best known was that of the Carbonari (q.v.; see also MAZZINI). At the same time there were similar societies, with similar revolutionary or democratic or constitutional aims, in other countries of Europe, as the Burschenschaft and Landsmannschaft societies in Germany, the Associated Patriots in France, the Communeros in Spain, the Hetairia in Greece, the Society of United Slavonians and the Decabrists in Russia, the Polish Templars, and the associations known as Young Germany, Young Italy, Young Poland, Young Switzerland. The German Tugendbund (q.v.) was hardly a secret society in the proper sense of the term. Nearly all the political revolutions that took place in France during the course of the 19th century were greatly fomented by secret societies, especially the revolution of 1848. Here too should be mentioned the Omladina, a movement having for its headquarters Servia and Belgrade, and for its objects the establishment of a republican pan-slavic confederation. The most momentous movements of a socio-political tendency that have sprung up on the Continent, and spread to some extent to England, are those of the Nihilists (q.v.), the Anarchists, and various sects of extreme Socialists (cf. INTERNATIONAL).

Ireland has been the breeding-ground of political societies directing their efforts against the English rule, or against one or the other of the two religious bodies in the island (Protestants and Roman Catholics), though motives arising out of agrarian distress have generally played an important part in the agitations these societies have set agoing. The White Boys, the Oak Boys, Right Boys, Peep o' Day Boys (see RIBBONISM), the United Irishmen, the Fenians, the Land League movement fostered by Mr Parnell (q.v.), are all well-known cases in point; see also ORANGEMEN.

There are perhaps no peoples in the world who favour secret societies more than the Chinese and the inhabitants of the United States. But whilst the objects of these associations in the former country are mostly political, in the latter they are predominantly social. The most powerful organisation of this nature in China—indeed its ramifications extend to all parts of the world where Chinamen are allowed to settle—is the Tien-ti Hwuy (Union of Heaven and Earth), which presents many features analogous to Freemasonry, such as secret signs, solemn initiation ceremonies, peculiar observances, and so forth; but its principal object seems to be the overthrow of the existing Manchu dynasty and the restoration of the last Chinese dynasty of the Ming. The White Lily is very wealthy and very strict in its rules, and its members are popularly accredited with the possession of magical powers. But about the real purposes of this, as of most other secret societies that exist amongst the Chinese, our information is exceedingly scanty. The Society of the Elder Brethren, which is, generally speaking, a combination of the most lawless elements of the population in the central provinces (Honan to Hunan), proclaims a fanatical hatred to all foreigners, including the Manchus. Secret societies of all kinds, and for nearly all conceivable purposes, are found in the United States, from the Vigilance Societies (q.v.), formed in the western states for the preservation of public order, to the Phi Beta Kappa and similar associations in the colleges and universities. The Danites, the Knights of Labour, the Ku-Klux Klan, the Molly Maguires (see these articles) may be instanced among notable organisations of native growth; the Maffia (q.v.) and some European societies have also extended their ramifications hither.

See C. W. Heckethorn, *Secret Societies of all Ages* (2 vols. 1874), where other books are quoted; T. Frost, *Secret Societies of the European Revolution* (1876); L. de la Hodde, *Secret Societies of France* (Philadelphia, 1856); F. H. Balfour, *Waifs and Strays from the Far East* (Lond. 1876), and a paper by him in the *Journal* of the Manchester Geographical Society (January 1892); and *Harper's Magazine* (September 1891).

Secret Writing. See CRYPTOGRAPHY, INK.

Secrole. See BENARES.

Sector, in Geometry, is a portion of a circle included between two radii and the intercepted arc of the circumference. The area of a sector is equal to that of a triangle whose base is equal in length to the intercepted arc, and whose perpendicular height is equal to the length of the radius.

Secularism is the term applied to a system of ethical principles advocated from about 1846 by the present writer. It is a new form of Free Thought seeking human improvement by the instrumentality of material means; and it aims to substitute the piety of usefulness for the usefulness of piety, and to treat error as a defect of knowledge rather than a defect of right intention. It takes as its axiom that what is best for humanity will command the approval of the author of humanity; what is 'best for humanity' being determinable by reason, tested in this life by the experience of this life. Experience teaches that science is the providence of man. Science teaches that improvement and progress can be surely attained by the wise use of material agencies. Material agencies act by causation—the law alike of nature and mind. Causation in will shows that, if men can be induced to pursue that conduct which is most useful, habit will render it the most agreeable. Causation in opinion implies that error can only be eradicated by the eradication of its cause. False ideas can only be extirpated by true ideas.

Hence the social aim of Secularism is to establish those material conditions in which, as far as forethought can compass them, it shall be impossible for a man to be depraved or poor. Morality of conduct—the main thing in this life—is determined by its conduciveness to the welfare of others as well as ourselves. This utilitarian rule has this advantage, that, while the strongest faith may co-exist with the greatest ignorance, utilitarian morality can only begin with intelligence, and the morality will be on the whole the greater the wider intelligence becomes.

Since the Secularist's profession is that mankind can be largely improved by well-devised *material* means, it belongs to him to inculcate a sense of responsibility for the condition of the world, so far as his exertions or influence can extend. The theological mind cares mainly for the souls and little for the social welfare of others. The Secularist holds that Truth and solicitude for the social welfare of others are the proper concern of a soul worth saving. Only minds with goodness in them have the merit of future existence in them; minds without veracity and generosity die; the element of death is in them already. The majority of people conduct life by believing what they wish, not by conforming to what they know—an easy, loose, pleasant kind of faith which commands many followers; belief without inquiry and action without the sense of social responsibility are always popular. He who undertakes the duty of selecting his principles protects himself from hereditary error. Every step towards reasoned truth implies thought, investigation, patience, courage, and accountability.

But to acquire truth thought must be free, unintimidated by any threat or penalty, legal, spiritual, or social; if inquiry must end in a prescribed conclusion or the inquirer perish everlastingly, no one but a fool would inquire at all. Unless men regard truth as higher than consequence thought must be sterile. Even inquiry, with whatever courage conducted, would be sterile without the right of free publicity of the results; the publication of new truth is the duty of the thinker, and his silence or supineness is a social crime. The free search, the free publicity, the free criticism, and free action of opinion are necessary secular conditions—conditions which have never been insisted upon as necessary to spiritual life. Though these conditions are used by science they are not claimed by it, being outside its province. Secular-minded thinkers alone have formulated and vindicated these conditions.

A main object of Secularism is to establish morality on grounds independent of Christianity, for so long as morality is supposed to have but that foundation it will not be influential on those who reject or do not accept Christianity. There is unquestionably a vast outlying class in every European country, and still more in India, who are without the pale of Christianity. Secularism is intended for these, and for all who deem theology indefinite, inadequate, undesirable, or unreliable. The object of Secularism is to afford these classes a knowledge of principles addressed to their common reason and intelligence, by an appeal to principles of a secular nature, common to humanity in every state and clime. The reality of Deity and a future state, being indeterminable by the experience of this life, are not secular questions; Atheism and Theism are alike without the means of demonstrating their own truth, and, though they may be subjects of personal belief, cannot be secular tenets—provable by experience. What is incapable of proof is usually decided by desire, and is without the conditions of uniformity or certitude. Morality, which fulfils the conditions of the highest religion, is attainable irrespective of belief in things outside this world. The uses of the universe are no more dependent upon the knowledge of its origin than the uses of a habitation are dependent on the knowledge of its architect.

Secularism does not ask to be esteemed a Christian system as Christianity is commonly accepted, but an ethical system. So far as Christianity is moral Secularism has common ground with it; but its reasons for being moral are not Christian reasons, but human considerations alone. Christianity attaches salvation to belief; Secularism seeks it in conduct. Christianity holds that inquiry must end in faith. Secularism teaches that regardless of consequences it should end in truth, and maintains intelligent sincerity to be sinless—not errorless, but without guilt. The doctrines of eternal perdition for honest dissent, of the natural depravity of man, of the wilfulness of an uncaused will, and of deliverance by prayers are immoral, discouraging, and traitorous; and secular controversy on the moral tendencies of these tenets is alone useful as advancing and vindicating secular ideas. Upon questions of miracles, prophecy, genuineness or inspiration of Scripture Secularism troubles itself little. If miracles are good it is a pity they have ceased; morality needs no inspiration. Precepts have no force unless corroborated by experience, and it is ill with men when they take authority for truth, instead of truth for authority.

Secularism does not say there is no light or guidance elsewhere, but maintains that there is light and guidance in secular truth, whose conditions and sanctions exist independently, and act independently. Secular knowledge is that kind of knowledge which is founded in this life, which relates to the conduct of this life, conduces to the welfare of this life, and is capable of being tested by the experience of this life. Mathematics, botany, chemistry, political economy are secular subjects of instruction; Secularism includes the education of the conscience. If a sum in arithmetic is wrong it can be proved by a new way of working it; if a medical recipe is wrong the effect is discoverable on the health; if a political law is wrong this is sooner or later apparent in the disaster it brings with it; but if a theological belief is wrong we must die to find it out.

Secularism is separateness and does not confuse together distinct things. By repute there are two worlds—the unknown and known. The interpreter of the unknown is theology; the interpreter of the known is experience, which teaches the uses of this world. Since mankind would perish if all were called upon to agree upon the authorship of the world before using it for the purposes of life, the Secularist forbids no opinion and gives none on a matter beyond his knowledge. He does not undertake to say whether nature is the outcome of intellect, or intellect the outcome of nature. He believes that there is no religion higher than truth, and that the reverence of that which is honest, and just, and compassionate exalts humanity; that manliness is self-helping and not mendicant, and vexes not the ears of the All-Wise with capricious supplications. Secularism seeks to create independent thinkers in all parties, and its adherents are content when their advocacy induces others in religious, social, and political movements to follow in the path of reason, experience, and material improvement.

See the following works by the present writer: *Principles of Secularism* (1855), *Secular Review* (1876), *Present Day* (1886), *Trial of Theism accused of obstructing Secular Progress* (1868). See also AGNOSTICISM.

Seculars. See CLERGY.

Secunderábad. See HYDERABAD.

Securite, the name of a flameless explosive, a granulated yellow powder understood to be a combination of ammonium nitrate and one of the benzol derivatives.

Security, in legal language, means a right conferred on a creditor which makes him secure or certain to recover what is due to him. Security may be given by setting aside some part of the debtor's property to answer the creditor's claim; for the modes in which this may be done, see PAWNBROKING and MORTGAGE. 'Securities for money' is a very wide term, including the shares, stocks, and debentures of public companies, &c. See Cavanagh's *Law of Money Securities* (2d ed. 1885) for a compendious account of the English law relating to the subject. And see the articles CAUTION, GUARANTY.

Sedalia, capital of Pettis county, Missouri, 188 miles by rail W. of St Louis. It has large railway-shops, flour-mills, and manufactories of woollens, machinery and agricultural implements, wagons, furniture, and soap. Pop. (1890) 14,068.

Sedan, a town and frontier fortress of France, dept. of Ardennes, stands on the Meuse, 64 miles by rail NE. of Rheims. Colbert founded here cloth-factories, the fabrics of which have a European reputation; some 10,000 workmen are employed in this industry and its branches. Various branches of metal-working are carried on, and there is an active trade in wool. Pop. (1872) 13,807; (1886) 19,100. The fortress, or rather the citadel, capitulated to the Germans in 1815; but Sedan is chiefly noted for the surrender (September 2, 1870) of Napoleon III. and an army of 86,000 men, with all their accoutrements and baggage, to the Germans in the Franco-German war. The fortress was dismantled after 1875. Marshals Turenne and Macdonald were born here. Previous to its incorporation with France (1642) it was the capital of an independent principality (that of the Counts de la Marck and later dukes of Bouillon) and a Protestant stronghold. Its industrial prosperity was largely due to the influx of Huguenots; and at its theological seminary, famous until the revocation of the Edict of Nantes, notable Scotsmen such as Andrew Melville taught.

Sedan Chair, a portable covered vehicle for carrying a single person, borne on two poles by two men. The name is derived from the town of Sedan, where this species of conveyance is said to have been invented. The Duke of Buckingham used one in the reign of James I., a proceeding which gave general offence, it being made matter of public remark that this royal favourite used his fellow-countrymen to do the work of beasts. In September 1634 Sir Sanders Duncombe got a letter patent, granting him the sole right and privilege for fourteen years to use and let for hire within London and Westminster 'covered chairs' to prevent the unnecessary use of coaches; according to Evelyn he got the notion from Naples. Sedan chairs were largely used during the greater part of the 18th century, being found very well adapted for transporting persons, in full dress, to public and private entertainments. Not only were there numerous public conveyances of this kind in London and all considerable towns, but the owner of every large mansion had his private sedan handsomely fitted up. In Edinburgh at the close of the 18th century sedan chairs were far more numerous than hackney coaches, and were almost all in the hands of Highlanders. Sedans are perhaps hardly yet quite extinct, having been in use in London so late at least as 1830, at Winchester as 1851, at Peterborough and Edinburgh as 1860, at Genoa as 1882, at Newcastle as 1885, and at Bury St Edmunds as 1890. Sedan chairs have also been employed as ambulances for conveying sick persons to hospitals.

Sedatives are substances or measures which exert a depressing effect on any part of the body. They are called pulmonary, nervous, gastric, cardiac, &c. sedatives according to the special part of the organism on which they exert their effects. They are employed to relieve pain, and to relieve over-activity and hyper-excitability of any organ or system. They embrace a very large number of commonly used medicines.

Sedbergh, a town in the West Riding of Yorkshire, on the Rawthey, 72 miles NW. of Skipton. It has a Norman church and a grammar-school (1551) of high repute, where Sedgwick was educated and Hartley Coleridge was a master. Pop. of township, 2374. See the Rev. W. Thompson, *Sedbergh, Garsdale, and Dent* (Leeds, 1892).

Sede'runt. See ACTS OF SEDERUNT.

Sedge. See CAREX.

Sedgefield, a town of Durham, 9 miles NW. of Stockton, with a cruciform Early English church and a grammar-school. Pop. of township, 2601.

Sedgemoor, a marshy district in the middle of Somersetshire, 5 miles SE. of Bridgewater, was the scene of the fight between 4000 soldiers of King James II. and 8000 of the undisciplined followers of the Duke of Monmouth, on 6th July 1685; the latter were defeated, with the loss of a thousand slain on the battlefield and several hundreds more in the subsequent pursuit and in the executions that followed. The account of the fight in Macaulay's *History* should be read, and also the description in Blackmore's *Lorna Doone*.

Sedgley, a town of Staffordshire, 3 miles S. of Wolverhampton, with coal-pits and ironworks. Pop. (1881) 14,874; (1891) 14,961.

Sedgwick, ADAM, for more than fifty years Woodward professor of Geology at Cambridge, was born at Dent in Yorkshire in 1785, graduated from Trinity College, Cambridge, in 1808, and for the next ten years lectured as a Fellow of his college. He was then elected professor of Geology (1818); and in the following year, on the foundation of the Cambridge Philosophical Society, he was chosen one of its secretaries. For many years he took an active part in the discussions of the Geological Society of London, of which he was president in the years 1829 to 1831. Most of his writings were couched in the form of papers contributed to the *Transactions* of these two societies. His best and most successful labour was expended upon the investigation of the palæozoic and crystalline rocks; and his longest work was a dissertation on *British Palæozoic Rocks and Fossils* (Lond. 1851–52). Along with Murchison (q.v.) he made a systematic study of the geology of the Alps, and of the Devonian system in England. Although he did admirable service in establishing geology on a thoroughly scientific basis, Sedgwick was in other regards firmly rooted in distinctively conservative ideas: he made a trenchant attack upon *The Vestiges of Creation* in the *Edinburgh Review*, and put himself in strong opposition to Darwin's *Origin of Species*. He was canon of Norwich Cathedral from 1834, and for some years held the office of vice-master of his college. His death occurred at Cambridge, on 25th January 1873. In 1890 appeared 2 vols. of his *Life and Letters*; in 1891 it was resolved to build at Cambridge a Sedgwick Memorial Geological Museum.

Sedimentary Rocks. See GEOLOGY, p. 152.

Sedition, a general name given to such offences against the state as fall short of treason. In the law of England it is not a strictly technical word.

writing, publishing, or uttering words tending to excite subjects to insurrection, though not urging them to rebellion or total subversion of the government, come under the denomination of seditious libel, and seditious meetings or assemblies are punishable as misdemeanours. The crime consists in the intention to excite disaffection against the sovereign, the government, or the administration of justice, or to excite the sovereign's subjects to attempt, *otherwise than by lawful means*, the alteration of any matter in church or state by law established, or to promote ill-will and hostility between different classes of such subjects.

In Scotland sedition is distinguished from Leasing-making (q.v.), in so far as the object of the latter is to disparage the private character of the sovereign, while the former crime is directed against the order and tranquillity of the state. The punishment of sedition, formerly arbitrary, is now restricted to fine and imprisonment. See Lord Cockburn's *Trials for Sedition in Scotland* (2 vols. 1888).

Sedley, Sir Charles, courtier and poet, was born at his father's seat at Aylesford, Kent, in 1639, a maternal grandson of the famous Sir Henry Savile. He was educated at Wadham College, Oxford, repaired to court at the Restoration, and soon became notorious at once for debauchery and wit. Later he sat in parliament for New Romney, retired from court, and joined the party of William at the Revolution, out of *gratitude* to James, who had seduced his daughter, and made her Countess of Dorchester. 'Since his majesty has made my daughter a countess,' said he, 'it is fit I should do all I can to make his daughter a queen.' Johnson's line, 'And Sedley cursed the form that pleased a king,' has kept alive the memory of this sordid amour, but it is worth noticing that the daughter, speaking of what attracted the king, decries her own beauty with something of her father's wit: 'It cannot be my beauty, for he must see that I have none; and it cannot be my wit, for he has not enough to know that I have any.' Sedley survived till 1701. He left six plays, among them *The Mulberry Garden* and *Bellamira*, but what little fame remains to him now rests solely on a few songs and *vers de société*. It is enough to name three, 'Phillis, men say that all my vows;' 'Ah, Chloris, that I now could sit;' 'Love still has something of the sea,' to make good a claim to unusual gracefulness of fancy and mastery of form. Even his licentiousness does not wear the open grossness of the age.

Seduction, in English law, means the act of decoying away a servant or member of a family from his or her duty; in a narrower sense it includes offences against the chastity of women, where the offender accomplishes his purpose by persuasion, not by force. It is not a criminal offence unless the facts are such as will support a charge of Rape (q.v.) or Abduction (q.v.). No action can be maintained by a woman who is seduced, however basely or deceitfully the seducer may have acted; but a master or mistress may sue in respect of loss of service caused by the seduction. If a father or mother can make out loss of service, damages can thus indirectly be recovered for the seduction of a daughter; and it is the inveterate practice of juries to give 'exemplary damages' in such cases, if the conduct of the defendant has been heartless or dishonourable. The rule of law is most irrational: a rich man, whose daughter occasionally makes his tea, can recover damages if she is seduced; a poor man, whose daughter is in a situation away from home, cannot. In Scotland the woman can sue in her own name if deceit has been used; but the difficulty of showing that the deceit was the only cause of the injury prevents such actions from being common. Redress is sometimes obtained by an action for breach of promise of marriage or (in Scotland) by an action of declarator of marriage; and the father of an illegitimate child can be compelled to maintain it.

Sedulius. See Hymn, Vol. VI. p. 46.

Sedum, a genus of plants of the natural order Crassulaceæ, having the calyx in four to eight (usually five) deep segments, which often resemble the leaves, the same number of spreading petals, twice as many stamens, and four to eight (usually five) ovaries, each with a nectariferous scale at the base. The species are numerous, with succulent, often roundish leaves, and pretty, star-like flowers. Many of them grow on rocks, whence the English name Stone-crop. They are natives of the temperate and cold parts of the northern hemisphere; some are British. They have no important uses; some are refrigerant, others are acrid. Among the British species are *S. telephium*, popularly called Orpine, sometimes used as a diuretic, and *S. acre*, the most common, whose brilliant yellow flowers adorn the tops of old walls, the *debris around quarries, &c. Many of the dwarf*-growing species are employed in the now popular style of flower-gardening called 'carpet-bedding.'

Seed. In the higher plants, which are called Phanerogams because of the conspicuousness of their flowers or reproductive organs, the egg-cell lies within an Ovule (q.v.), and after fertilisation grows into an embryo plant, with one or two primary leaves—all before separation from the parent plant. What is separated, to begin in favourable conditions a new and independent life, is a seed, which may be defined as a ripe ovule containing an embryo plant. So distinctive of the Phanerogams is this mode of reproduction by seeds, that they are often and conveniently called Spermaphytes or Seed-plants.

From the article Ovule the reader will understand how the seed is formed, how a mass of tissue—the nucellus—borne by the carpellary leaf contains a female spore or 'embryo-sac,' whose nucleus divides into a female nucleus or oosphere (which will develop into an embryo if fertilised) and a number of other nuclei of minor importance. The fertilised oosphere, within the embryo-sac, imbedded in the nucellus, and surrounded by the coats of the ovule, develops into an embryo plant, and the whole structure is called a seed.

Structure of the Seed considered in relation to the Growth and Germination of the Embryo.—The segmented egg-cell within the embryo-sac gives rise to the embryo and to a 'suspensor' which moors it. The figure on p. 300 shows somewhat diagrammatically the embryo moored to the top of the embryo-sac by the suspensor; the base of the embryo next the suspensor is the region from which the radicle or young root will spring; the depressed apex at the opposite pole of the embryo is the region from which the plumule or young stem will shoot forth; the two sides form the young cotyledons or seed-leaves.

The embryo is the essential part of the seed; the other structures are subsidiary to its nurture, protection, and germination. Of these other parts of the seed the stored food material is of great importance, for after separation from the parent the embryo grows and sends out its rootlet, and pushes up its stem and expands its delicate leaves, in great part on the strength of what nutritive material it or the seed contains. This nutritive material, or 'albumen' as it is often called, out of which the first new parts of the young plant will be in great part built up, is formed after fertilisation—the physiological conditions are not understood—and is disposed within the seed in three different ways in relation to the embryo. It may lie in the cells of the nucellus, around but not within the embryo-sac, as in the seeds of bananas and ginger; then we call it perisperm. Or it may lie in more intimate relation to the embryo, within the embryo-sac (where a median nucleus seems to bear some relation to its formation), as in the seeds of wheat and castor-oil; then we call it endosperm. Sometimes there may be both endosperm and perisperm, as in water-lilies. But in many cases there is neither endosperm nor perisperm, all the food material being stored within the embryo itself—in its cotyledons—as in the pea and wallflower, apple and almond. Such seeds are somewhat confusedly called ex-albuminous.

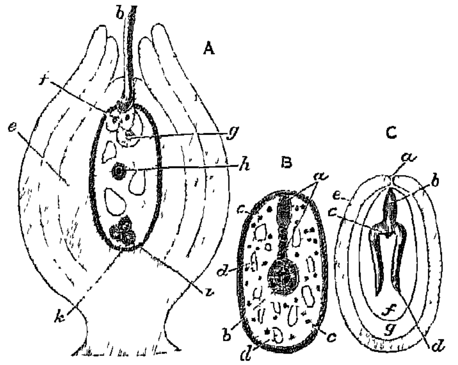


Diagram showing general structure of Seed (from Parker's *Elementary Biology*):

A, section of ovule: *b*, pollen-tube; *e*, nucellus; *f*, accessory cells or synergidæ; *g*, ovum or egg-cell; *h*, central nucleus of embryo-sac; *i*, antipodal cells of embryo-sac; *k*, embryo-sac.
B, embryo-sac, showing *a*, suspensor; *b*, embryo or segmented ovum; *c*, nuclei, *d*, vacuoles.
C, section of a seed, showing *a*, the micropyle; *b*, embryo with embryonic root; *c*, embryonic stem; *d*, cotyledons; *e*, external seed-coat; *f*, endosperm; *g*, perisperm.

The food materials, which are so often and by no means accurately summed up in the term albumen, vary in different kinds of seeds, but in a general way we may say that they consist of starchy, fatty, and proteid substances in varying proportions. In the development of animals they have their analogue in the yolk, and the analogy is especially true of the endosperm which is formed within the embryo-sac. But this analogy cannot be pressed, and it is perhaps more important to notice that the three ways in which the nutriment occurs—in the nucellus (perisperm), in the embryo-sac (endosperm), and in the embryo itself—form an intelligible series. The perisperm, which is least common, occurs in the nucellus—an outgrowth of the carpel—i.e. in the sporangium of the sporophyte generation (see FLOWER, FERN, OVULE). The endosperm occurs in the embryo-sac, has its centre in a central nucleus (formed from the fusion of two of the eight nuclei into which the primary spore-cell divides), and is therefore included in the prothallium of the gamophyte generation. Lastly, and most frequently, the nutrition may be stored within the embryo which results from the fertilisation of the egg-cell of the gamophyte.

Structure of the Seed considered in relation to the Protection of the Embryo.—As the embryo plant is a delicate structure, and as its separation from the parent plant is attended with vicissitudes, for the seed may be blown or carried into unfavourable conditions, and as most of the seeds which are liberated are not at once ready to germinate, it is important that the life of the embryo should be protected. This necessary protection is supplied in various ways. Around the ovule a double investment usually grows, and part of this investment is modified as the husk of the seed. The modification becomes marked as the seed grows ripe, as it begins to be ready for separation from the parent, as its supply of water begins to fail, as its vitality becomes more dormant; in fact the modification, which is a most useful one, is in part a necessary result of the physiological conditions of seed-ripening. In the modified husk it is generally possible to distinguish a thin, relatively unimportant internal tegmen from an outer, thicker, resistent testa. This testa may be leathery or woody, fleshy or gelatinous, smooth or hairy; it is variously adapted for the protection of the enclosed embryo. We may compare it to the shell or case which often surrounds the animal embryo. There is usually some relation between the nature of the seed-coat and that of the pericarp which surrounds the whole fruit; for in indehiscent fruits with tough walls (as in achenes and nuts) the seed-coat remains thin, while in dehiscent fruits the seed-coat is usually thick and hard. See GEOGRAPHICAL DISTRIBUTION.

Apart from the husk, the ripe seed is sometimes marked by a growth from its base or stalk. This is called the aril, and may be hairy as in willows and poplars, fleshy as in Euonymus, peculiarly shredded as in the mace of *Myristica aromatica* or nutmeg. When the growth from the base or from the funiculus of the seed is all on one side, it is called a caruncle, as in *Chelidonium majus*, *Viola tricolor*, and *Ricinus communis*. The outer surface of a liberated seed may also bear a mark at the place (hilum) where it separated from the funiculus; this is well seen in the common bean. Sometimes also a small opening or depression (*cicatricula*) persists as a remnant of the micropyle or aperture by which the pollen-tube passed between the coats of the ovule. In many cases the region marked by an external scar, corresponding to hilum or to micropyle or to both, is of special importance, the tissue of the seed-coat being modified so as to act as a sponge through which water soaks in to the embryo within. Many of the hard coats of seeds have, instead of this special sponge, numerous minute canals perforating their dense substance.

Structure of the Seed considered in relation to Seed-scattering.—Already in the article FRUIT reference has been made to adaptations which secure the dispersion of the seeds. Oftenest the dispersion depends upon the fruit, which may burst violently so that the seeds are scattered, or may be juicy and palatable so that it is eaten by birds and other animals, the indigestible seeds being in this way carried far and wide. Sometimes the fruit and the seed are virtually though not technically the same, as is the case in thistle-down, in which each little winged fruit borne about by the wind contains a single seed. Sometimes, however, the seeds themselves are borne about by the wind, as in willows and poplars, willow-herbs (Epilobium), cinchona, *Asclepias syriaca*, &c. The hairs which serve as parachutes to the seeds of poplars, willows, and the like are accessory growths outside the seed; a similar rich growth of cottony hair is characteristic of Gossypium and Eriodendron. It should also be noted that in many cases the seed is adapted to anchor itself, for the surface is often ridged or peaked, as in Hyoscyamus, Papaver, Nigella, or becomes glutinous in moist places, as in flax and some species of Plantago.

For further details as to the structure of seeds, consult morphological works such as Sachs's *Text-book of Botany*; for further details as to seed-scattering and the like, see

Kerner's *Pflanzenleben*, vol. ii. (Leip. 1891); for hints as to the practical study of seeds, see Strasburger's *Practical Botany*, trans. by Hillhouse (2d ed. 1889).

Vitality of Seeds.—Although the seed is a complex structure, it is usually able to remain for weeks, months, or even years in a state of dormant life hardly distinguishable from death except in its power of reawakening. We usually say that a seed is ripe at its separation from the parent plant, but this ripeness is *not coincident* with readiness to germinate. Sometimes indeed, as in the sheaves of corn in a wet season, the seeds may germinate before they leave the parent plant; those of ephemeral plants usually germinate as soon as they are scattered. In most cases, however, seeds are not ready to germinate until after they have remained for some time dormant. The seed of the mistletoe is ripe in autumn, but it does not germinate until April or May of the following year; that of *Draba verna* requires ten or eleven months of quiescence; that of *Euphorbia cyparissias* remains under ground from four to seven years; that of *Euphorbia exigua* is said to lie dormant for nine years. In some cases the reason of the prolonged postponement of germination is to be found in the hardness and thickness of the husks which surround the seeds, and in the slowness with which water seems able to penetrate into the dense cells; and it is likely that time is also required for ferments which the seeds contain to do their work of preparing the reserve food material for use in germination.

Seeds vary greatly in their powers of retaining their life. Those of the willows and poplars are peculiarly short-lived; unless they land in moist places they usually die in a few days. 'Seeds rich in ferment quickly lose their power of germinating. Ripe acorns will not germinate after a year, nor coffee-beans after six months. Nor do those which are rich in oil survive nearly so long as those whose reserve-products consist mainly of starch.' There is no doubt that carelessly-made experiments have given rise to a much exaggerated estimate of the powers of retaining vitality which seeds possess. Thus, we often hear of mummy wheat which has germinated after many centuries; but this assertion has not been substantiated. Indeed, modern experiments with the seeds of cereals show that they lose their vitality after ten years at most, and usually much sooner. Those of leguminous plants may, however, survive for several decennia. The vitality of seeds is also illustrated by the fact that some dry seeds can survive very high and very low (100° C. and - 120° C.) temperatures. As to the real state of the protoplasm inside those seeds which remain so long without either living or dying, we are not yet in a position to make definite statements (see J. Wiesner's *Biologie der Pflanzen*, 1889).

Uses of Seeds.—As seeds are often rich in starchy, fatty, and proteid substances, their importance as food is very great. Those of cereals and leguminous plants are especially valuable; and the seeds of hazel, chestnut, cocoa-nut, *Chenopodium Quinoa*, Bertholletia, *Pinus cembra*, and many others are also edible. Others, such as mustard and nutmeg, furnish spices; many others, such as linseed, almonds, cocoa-nut, castor-oil plant, yield oil; cotton-wool surrounds the seeds of Gossypium, &c.; vegetable ivory is the dense endosperm of Phytelephas. Some seeds are rich in stimulants, as in coffee and kola plants; many, such as *Strychnos nux vomica* and Physostigma, yield drugs.

Seeland (Dan. *Själland*). See ZEALAND.

Seeley, JOHN ROBERT, the unavowed author of *Ecce Homo*, was born in London in 1834, the third son of the publisher, Robert B. Seeley (1798–1886). He was educated at the City of London School, and at Christ's College, Cambridge, and graduated in 1857 first (equal with three others) in the first class in the classical tripos. Next year he became a Fellow of his college, later a lecturer there, then at his old school, but in 1863 was professor of Latin in University College, London, in 1869 of Modern History at Cambridge, with a fellowship at Christ's in 1882. *Ecce Homo* appeared anonymously in 1865, and excited an extraordinary commotion in the religious world in England, which was startled almost as much by its consummate literary excellence and its spiritual reverence as by the absence of the supernatural element. As a study of the human character of Jesus it still stands unrivalled. It was followed in 1882 by *Natural Religion*, a work only less valuable.

Other, and acknowledged, works of Professor Seeley's are *English Lessons for English Readers*, in collaboration with Dr E. A. Abbott (1869); *Lectures and Essays* (1870); an edition of *Livy*, Book I. (1871); *Life and Times of Stein: or Germany and Prussia in the Napoleonic Age*, a work that has satisfied even German scholars (3 vols. 1879); *The Expansion of England* (1883); *A Short Life of Napoleon the First* (1885); and *Growth of British Policy* (1892). Professor Seeley's occasional articles in the greater magazines on such subjects as Goethe, the House of Bourbon, &c., always command attention.

Segesta, or EGESTA, an ancient city in the north-west corner of Sicily, said to have been founded by the Trojans, was allied with the Carthaginians in 410 B.C., was conquered by the Syracusan Greeks in 307, and, again Carthaginian, revolted in 206 to the Romans, who greatly favoured it. The place suffered much from Saracen attacks, and now shows nothing but fine ruins, including a theatre and a great Doric temple. There are hot springs near the site, which was 6 miles from the sea, the present Castellamare representing what was the harbour of Segesta.

Segesvár (Ger. *Schassburg*), a town of Transylvania, on the Great Kokel, 60 miles by rail NE. of Hermannstadt, consists of an upper and a lower town. Pop. 8788, who weave cotton and linen. Here on 31st July 1849 the Hungarians were defeated by the Russians; Petöfi is believed to have been amongst the slain.

Segovia, an old city of Spain, stands at the northern foot of the Sierra de Guadarrama, 32 miles NNW. of Madrid. It occupies a rocky eminence 3300 feet above sea-level, is surrounded by ruinous walls with round towers, and consists of narrow uneven streets, with old, quaint, and stately houses, and numerous parish churches and convents. The fortress or castle is perched on the west extremity of the rocky height, and was originally Moorish, but has been gradually restored since its destruction by fire in 1862; its towers and windows command magnificent views. The cathedral (1521–77) is one of the finest specimens of Late Gothic in Spain. The grand aqueduct, built in the time of Trajan, is a very fine example of Roman architectural work. It consists of two rows of arches, the one resting upon the other, some 2600 feet long and 102 feet high. Wool-scouring and the manufacture of paper, pottery, and cloth are languidly carried on. Pop. (1887) 14,399. Segovia was a place of importance during the time of the Romans, and was frequently the residence of the kings of Castile and Leon. Charles I. of England lodged at the castle, September 13, 1623, and supped on 'certaine trouts of extraordinary greatnesse.' The unresisting town was sacked in 1808 by the French.—The province of Segovia has an area of 2714 sq. m. and a pop. (1887) of 154,457.

Segu, or SEGU-SIKORO, an important trading town of western Africa, stands on the Niger (here called the Joliba), 400 miles SW. of Timbuctoo. It was formerly the capital of a large native state, which has lost power under the successive conquests of the Toucouleurs, the Bambarra, and the French (1890). The traders are chiefly Arabs. Pop. 36,000. See Gravier, *Voyage à Segu* (1887).

Ségur, the name of a French family, originally of Guienne, distinguished both in arms and letters, as well as for its sufferings in the Huguenot cause. Its most famous members were the following: HENRI FRANÇOIS, Comte de Ségur (1689–1751), an able French general in the war of the Austrian succession. His son, PHILIPPE HENRI, Marquis de Ségur-Ponchat (1724–1801), fought in the Seven Years' War, became marshal in 1783, and outlived in his retirement the stormy scenes of the Revolution. The eldest son of this Philippe Henri was LOUIS PHILIPPE, Comte de Ségur d'Aguesseau (1753–1830), for five years ambassador at the court of St Petersburg, and a great favourite with Catharine II. He served in the American war of independence, hailed the great Revolution with delight, and, stranger still, retained in extreme old age that love of liberty that marked his early years—the last act of his life was a eulogium on the revolution of July. As a writer Ségur exhibits in fine perfection the national graces of style and spirit. Among his numerous writings are: *La Politique de tous les Cabinets de l'Europe* (1793); *Histoire de Frédéric-Guillaume II.* (1800); *Histoire Universelle* (1817); *Galerie Morale et Politique* (1817–23), a delightful work; *Mémoires* (1825–26). His chief works fill 33 vols. (1824–30). He left two sons, OCTAVE and PHILIPPE PAUL, the latter of whom (1780–1873) was a general of the first empire, took part in the fatal expedition to Russia in 1812, and wrote the story of the campaign, *Histoire de Napoléon et de la Grande Armée pendant l'année 1812* (2 vols. 1824). The work has had an immense success, and has been translated into almost all the languages of Europe. Other works were: *Lettre sur la Campagne du Général Macdonald dans les Grisons* (1802); *Histoire de Russie et de Pierre le Grand* (1829); *Histoire de Charles VIII.* (1835); *Histoire et Mémoires, 1789–1848* (1873).

There is a Life by Taillandier (Paris, 1875); see also Sainte-Beuve's *Portraits Littéraires*, vol. ii.

Seidlitz Powders (so named from the village of Seidlitz or Sedlitz in northern Bohemia, where there is a spring of natural aperient mineral-water with similar constituents) are composed of 120 grains of tartrate of soda and potash and 40 grains of bicarbonate of soda reduced to powder, mixed and enclosed in a blue paper, and 38 grains of powdered tartaric acid in a white paper. The contents of the blue paper are dissolved in from half a tumbler to a tumbler of water, and those of the white paper are then stirred in. The mixture should be taken while the effervescence from the liberation of the carbonic acid is still going on. These powders act as an agreeable and mild cooling aperient. If a stronger dose is required, either an increased quantity of the powder may be used, or a little sulphate of magnesia (about a drachm) may be added.

Seine, one of the four chief rivers of France, rises on the slope of the plateau of Langres, north-west of Dijon, and flows north-westward, with many windings, past Troyes, Fontainebleau, Melun, Paris, St Denis, St Germain, Mantes, Elbeuf, and Rouen, through a total course of 482 miles, and pours its waters into a wide estuary of the English Channel, on which stand the ports of Harfleur, Havre, and Honfleur. It is navigable for boats from Marcilly, 350 miles from its mouth, and since 1890 the canalisation of the Seine has been one of two projects (the other a ship-canal) for connecting Paris with the Atlantic (see PARIS, p. 767). The Seine drains an area of 30,000 sq. m.; receives the Aube, Marne, and Oise from the right, and the Yonne, Loing, Essonne, and Eure from the left; and is connected by canals with the Somme, Scheldt, Meuse, Rhine, Saône, and Loire. Works for keeping open a navigable channel through the estuary, which is liable to silt up, were commenced as far back as 1848, and were continued for more than twenty years. In consequence of these engineering works 28,000 acres of land have been reclaimed, and vessels of 2000 tons, drawing 20 feet of water, can get up to Rouen. Moreover a canal has been constructed to give Havre connection with the Seine at Tancarville, so that vessels using this channel can avoid the uncertainties of the deeper estuary. See L. F. Vernon-Harcourt, 'The River Seine,' in *Proc. Inst. Civil Engineers* (1886), and the beautiful engravings in *The Seine and Loire* (Turner's *Rivers of France*) published in 1886.

Seine, the metropolitan dept. of France, completely enclosed by the dept. of Seine-et-Oise, is a portion of the former province of Île-de-France, and derives its name from its principal river, the Seine. One-sixth of its area is covered by the city of Paris (q.v.), and the rest is thickly studded with the suburban villages of the capital—Boulogne, Puteaux, Clichy, Montreuil, &c. It is at once the smallest and the most populous dept. in the republic: its area is 185 sq. m.; its pop. in 1876 was 2,410,849, and in 1891, 3,144,595. From south-east to north-west it is traversed for 37 miles by the windings of the Seine, which receives the navigable Marne at Charenton and the Bièvre at Paris. The surface is marked by undulations and low hills, the highest, Mont Valérien and Mont Bicêtre, reaching 650 feet. The scenery—of which the woods of Verrières, Meudon, and Saint-Cloud, together with those of Vincennes and Boulogne, transformed into parks, and watered by artificial rivers and lakes, are perhaps the most striking features—is wonderfully charming. A network of canals and railways, the latter converging in the capital, afford easy means of transit in any direction. The soil is not naturally fertile, but, owing to the skill of the farmers and gardeners, who obtain abundant supplies of manures from the metropolis, the country around Paris and its suburbs has been rendered remarkably productive. The culture of vegetables and fruits for the markets of Paris is one of the most important branches of husbandry. Enormous quantities of mushrooms are cultivated in the ancient quarries of Paris near Montrouge, and in the catacombs beneath the city. Quarries of gypsum and freestone abound, and are productive. Manufacturing industry is very active and extensive, but is principally concentrated in Paris and its suburbs. The arrondissements are Paris, St Denis, and Sceaux.

Seine-et-Marne, a dept. in the north of France, is bounded on the W. by the dept. of Seine-et-Oise, and forms a portion of that wide basin in the middle of which stands Paris. Area, 2214 sq. m.; pop. (1886) 355,136. The dept. is drained by the Seine and its tributaries (Yonne and Loing) and the Marne and its tributaries (Ourcq, Petit Morin, and Grand Morin). The surface is broken into a series of plateaus separated by valleys. Timber is grown in every part; and among the forests is that of Fontainebleau. The soil is generally fertile. Wheat, oats, potatoes, beet-root, and fodder crops are the chief productions. Building-stone, gypsum, clay, sand, and peat are extracted in large quantities. The manufactures are very varied, and embrace paper, sugar, porcelain and glass, spirits, flour, books, gloves, and other branches. The cheeses of Brie are well known, and so are the roses of Provins. The white grapes of Fontainebleau have a European reputation. The capital is Melun, and the arrondissements are Melun, Coulommiers, Fontainebleau, Meaux, and Provins.

Seine-et-Oise, a dept. in the north of France, encloses the metropolitan dept. of Seine. Area, 2163 sq. m.; pop. (1886) 618,089. The principal rivers are the Seine and its tributaries the Oise, Marne, Essoune, Bièvre, Epte, &c. The surface is pretty level on the whole, but the country is charmingly diversified by picturesque valleys and great forests. Vast quantities of wheat, oats, potatoes, beet-root, and fodder crops are produced; and there are several fine varieties of stone and clay. There are numerous branches of manufacture, the most important being porcelain (at Sèvres), paper, cotton, silk, and woollen stuffs, iron goods, sugar, spirits, books, chemicals, laces, fringes, &c. The dept. is divided into the arrondissements of Versailles, Corbeil, Étampes, Mantes, Pontoise, and Rambouillet, and the capital is Versailles.

Seine-Inférieure, a maritime dept. of northern France, formed out of the old province of Normandy, and bounded on the N. and W. by the English Channel. Area, 2330 sq. m.; pop. (1886) 833,386. The Seine flows through the southern districts; but a number of important though small streams flow north-west across the dept. and fall into the Channel. The hills of Caux extend from east to west, and to the south of them are rich pasture-lands, watered by the Seine and its affluents. The coasts are formed of chalk-cliffs, varying in height from 200 to 400 feet. This dept. is one of the most flourishing in all France, having many manufacturing establishments (cotton and woollen stuffs, dyeworks, cloth, flax, shipping, foundries, sugar-refineries, tobacco, chemicals, &c.), a large trade from Havre, Rouen, and Dieppe, and much prosperous farming (cheese, butter, cattle, wool). Cider is extensively made. The coast-fisheries are valuable. On its coast are the favourite seaside resorts of the Parisians—Fécamp, St Valery, Tréport, Dieppe, and others. The arrondissements are Dieppe, Havre, Rouen, Neufchâtel, and Yvetot. The capital is Rouen.

Seisin, or Sasine. See Feoffment, Infeftment.

Seismometer is an instrument for measuring shakings, tremors, and tiltings of the earth (see Earthquake). In its earlier and ruder forms it was merely a seismoscope or seismograph, and its indications or records could not be interpreted quantitatively. Such, for example, is Babbage's bowl of treacle, in which the liquid, tending by inertia to remain steady as the bowl moves with the ground, leaves a high tidal mark as an evidence of the earthquake. Probably, but by no means certainly, such an instrument would indicate the direction of the largest motion occurring in an earthquake. It could not, however, record the succession of oscillations that make up the shock, or give really comparative records of different earthquakes. Similar limitations exist in all forms of liquid seismoscopes, such as Mallet's and Palmieri's, in which mercury moving in glass tubes forms the 'steady body.' A complete seismometer must, indeed, be capable of recording the entire earthquake motion in time, so that the amounts and rates of motions in all directions can be readily estimated from the records. The practical realisation of such an instrument we owe to the labours of Ewing, Gray, and Milne, who, working simultaneously and more or less in concert, brought to bear upon the problem of Japanese earthquakes a rare combination of scientific knowledge and mechanical skill. Gray and Milne's Seismometer (see *Philosophical Magazine*, 1887) is perhaps the most complete of its kind, and is identical in principle with Ewing's Bracket Seismometer, which was the earliest instrument constructed for recording on the same sheet both the horizontal and vertical motions of small earthquakes. In these instruments there are three weights suspended by brackets, so that each has somewhere within it a 'steady point' with reference to one of the three directions, N. and S., E. and W., up and down. To these weights suitable levers are attached, which trace out on a smoked surface any desired magnifications of the relative motions of the earth and the corresponding steady points. Thus we obtain records of the three components of an earthquake motion; and from these the whole motion can be reconstructed and a model made of the complex motion of an earth particle, as has been done by Professor Sekiya of Japan. When the vertical motion is large, so that the earth's surface is thrown into distinct waves, these bracket seismometers fail to act as such. The precise meaning of a 'steady point' may be best obtained from consideration of a long pendulum with a heavy bob. We may suppose a pencil fixed to the bob and bearing lightly upon a sheet of paper resting on the ground. In an earthquake the ground moves, and with it the pendulum support. But the pendulum bob, because of its inertia, remains steady during the first motion, of which, consequently, we get a tracing on the paper. The subsequent tracing is a combination of the real earthquake motion and the slow swing of the pendulum itself. To get a perfectly steady point we should have to use an infinitely long pendulum. By a combination of an inverted unstable pendulum with an ordinary stable pendulum of convenient size, the stability may be reduced to neutrality, and a very satisfactory steady point obtained. This plan, first suggested by Principal Forbes, is very effectively realised in Ewing's Duplex Pendulum Seismometer. The record is a superposition of the whole horizontal motion, and gives definitely little more than the maximum displacement in direction and magnitude. For earth tremors and earth tiltings much more delicate instruments are needed than have been described. Of these Bertelli's Tromometer is the best known. For large and disastrous earthquakes the havoc wrought is the only seismoscope that can be depended upon.

Seistan, or **Hamoon,** Lake, a large, irregularly-shaped, shallow lake or swamp in the west of Afghanistan, close to the frontier of the Persian province of Khorassan, a division of which province (mainly steppe) is named Seistan after it. The lake is not a single expanse of water, but is divided into three depressions. Great part of the area is generally dry; but, as the basin has no outlet, when the Helmund (q.v.) and its other feeders are in flood this lake regularly overflows its boundaries, fertilising large tracts of country.

Sejanus. See Tiberius.

Selachoidei. See Cartilaginous Fishes.

Selaginella, a genus of heterosporous cryptogams, closely allied to the so-called Club-moss (see Lycopodiaceæ), with some 350 species—many of them cultivated in conservatories.

Selan'gor, a state of the Malay Peninsula, which since 1874 has been under British protection. It lies between Malacca and Perak, has an area of 5000 sq. m. and a pop. (1890) of 140,000, including many Chinese; contains rich deposits of tin; and grows tapioca, rice, and sugar. The capital is Kwala Lampur, which is connected by rail (22 miles) with Klang, the principal port of the state, on the Klang River.

Selborne, a pleasant Hampshire parish of 12 sq. m. and 1200 inhabitants, 5 miles SSE. of Alton station and 20 E. of Winchester. Gilbert White (q.v., 1720-93) has made it for ever famous by his *Natural History of Selborne* (1789). 'The Wakes,' the ivied house where he was born and died, was rebuilt in 1881; and the church, where he lies, was restored in 1877. Nothing remains of an Augustinian priory (1232).

Selborne, ROUNDELL PALMER, EARL OF, was born at Mixbury Rectory, Oxfordshire, November 27, 1812, and had his education at Rugby and Winchester and at Trinity College, Oxford. His course was exceptionally brilliant; he carried off the Chancellor's prize for Latin verse (1831), the Newdigate (1832), the Ireland scholarship (1832), took a classical first-class in 1834, was elected to a Magdalen fellowship, and took both the Chancellor's prize for the Latin essay (1835) and the Eldon Law scholarship. He was called to the bar at Lincoln's Inn in 1837, and became a Q.C. in 1849; sat for Plymouth in the House of Commons from 1847 till 1852, and again from 1853 till 1857; became Solicitor-general in 1861 under Palmerston, being at the same time knighted and returned for Richmond; and was Attorney-general from 1863 till the fall of the Russell government in 1866. His inability to accept Mr Gladstone's whole Irish Church policy prevented his accepting the Chancellorship in 1868, but he succeeded Lord Hatherley in 1872, and was created Baron Selborne. The year before he had represented the government as counsel before the Arbitration Court at Geneva. Selborne was ever active as a reformer in legal procedure, and his reign will remain memorable from the fusion of law and equity effected by his Judicature Act (1873). He fell with his party in February 1874, but returned to the woolsack in May 1880, and sat till the dissolution of 1885. He was raised to the rank of Earl of Selborne in 1882. He found himself unable to accept Mr Gladstone's Irish policy, and therefore in February 1886 declined a third term of office. Lord Selborne was chairman of the Commission for the reform of the University of Oxford, received its D.C.L. degree in 1863, and was elected Lord Rector of St Andrews in 1877. A learned hymnologist, he edited *The Book of Praise* (1863; 9th ed. 1892), an admirable selection. Other books are *Notes on some Passages in the Liturgical History of the Reformed English Church* (1878), *A Defence of the Church of England against Disestablishment* (1886), and *Ancient Facts and Fictions as to Churches and Tithes* (1888).

Selby, a market-town in the West Riding of Yorkshire, on the right bank of the Ouse, 15 miles S. of York and 20 E. of Leeds. The great cruciform parish church, measuring 283 by 59 feet, was the church of a mitred Benedictine abbey, founded in the 12th century by Hugh, sheriff of Yorkshire. It exhibits every style from Norman to Perpendicular; lost its south transept by the fall in 1690 of the central tower (meanly rebuilt twelve years later); and has undergone much restoration since 1873. Other edifices are a Roman Catholic church (1859), St James's Church (1868), and a modern market-cross. The river is navigable for vessels of 200 tons; and there is also a considerable carrying trade by railway and canal. Selby has manufactures of flax, ropes, leather, beer, &c., besides boat-building and brick-making. It is the traditional birthplace of Henry I. (1068), and in the Great Rebellion was recaptured from the royalists by Fairfax (1644). Pop. (1851) 5109; (1891) 6022. See W. W. Morrell's *History of Selby* (1867).

Selden, JOHN, an illustrious English scholar and jurist, was born at Salvington near Worthing in Sussex, in December 1584, studied at Hart Hall, Oxford, for three years, and then removed, first to Clifford's Inn, London, and afterwards to the Inner Temple, to study law. It was here that his great learning began to attract attention, and won for him the friendship of Camden, Usher, Sir Robert Cotton, and Sir Henry Spelman. As a conveyancer and chamber-counsel he acquired wealth, yet found time for studies at once profound and wide in range. Selden wrote his first treatise, relating to the civil government of Britain previous to the Norman Conquest, and entitled *Analecton Anglo-Britannicon* (1606), when only twenty-two years of age. In 1610 appeared his *Jani Anglorum Facies Altera* (Eng. trans. 1683), giving an account of the common and statute law of English Brittany to the death of Henry II., and also *The Duello, or Single Combat*, a history of trial by battle; and in 1614 was published his *Titles of Honour*, still an authority. Three years later appeared his erudite work on the Syrian gods, especially in their connection with the Old Testament, entitled *De Diis Syriis Syntagmata Duo*. His *History of Tithes* (1618) demolished their *divine right*, and brought down upon his head the fulminations of the clergy, much more noisy than convincing. Fortunately for his assailants the Privy-council suppressed the book and forbade him to reply. In 1621 Selden suffered a brief imprisonment for advising the parliament to repudiate King James's doctrine that their privileges were originally royal grants; in 1623 he was elected member for Lancaster, in 1626 for Great Bedwin, and in 1628 for Ludgershall, both in Wilts, and henceforward till his death he took a considerable part in public affairs.

He was sincerely attached to the cause of the parliament, and as sincerely opposed to the views of the court party and the king, but he was above all things a constitutional lawyer, and derived his ideas of the rights of the subject from the history of the nation, and not from religious fanaticism or metaphysical considerations. Still he 'loved his ease,' as Clarendon says, and so let things be done without protest of which he did not approve. In 1628 he helped to draw up the Petition of Right, and the year after he was committed to the Tower with Eliot, Holles, and the rest. After eight months' rigorous imprisonment he was transferred to the Marshalsea, but soon after was released through the favour of Laud, whereupon he retired to Wrest in Bedfordshire, the seat of the Earl of Kent. In 1640 he was chosen member of the Long Parliament for the university of Oxford; and now, when the struggle between the king and the nation began to point towards the fatal rupture, he was suspected of not being zealous enough by such as were themselves perhaps over-zealous. Already in 1635 he had dedicated to the king his *Mare Clausum* (an answer to the *Mare Liberum* of Grotius and the Dutch claims to fish off the British coasts), and there is evidence that Charles personally looked on him with favour. Selden was one of the committee of twenty-four appointed to draw up a remonstrance, and at this point his path first diverged from that of Hyde, yet without their friendship being impaired. He opposed vigorously the policy that led to the expulsion of the bishops from the House of Lords, and finally to the abolition of Episcopacy. Yet he adhered in the main to the cause of the parliament, driven by the complete arbitrariness of the king's later measures. He took no direct part in the impeachment of Strafford and voted against the Attainder Bill, and, though he furnished precedents for the measures taken against Laud, had no share in his prosecution.

ıt as a lay-member in the Assembly of
at Westminster (1643), and perplexed
ical colleagues sadly with his irony and
rning. Soon after he was appointed

ıe, the Greek moon-goddess, a daughter
erion and Theia, and sister of Helios
ın) and Eos (the Dawn). As sister of
r *Phoibos* ('shining') she had the name of
ɜnd latterly was identified with Artemis,
the identification was never quite exact,
mis always retained her reputation for
, while Selene had fifty daughters by her lover Endymion and several by Zeus. She is represented by the poets as a lovely woman with long wings and a golden diadem, riding across the heavens in a chariot drawn by two white horses, cows, or mules. See *Ueber Selene und Verwandtes*, by W. H. Roscher (1890).

Selenga, a river (740 miles) of Mongolia and Siberia, flowing by three arms into Lake Baikal. It is navigable from May till October for 200 miles from the Chinese frontier, and steamers and lighters ply on it.

Selenite (Gr. *Selēnē*, 'the moon'). This name is given to the transparent variety of Gypsum (q.v.). It occurs in distinct crystals belonging to the oblique or monoclinic system, or in folia. It is usually white (colourless), but sometimes it is tinged with red, yellow, green, gray, &c. Selenite is soft, easily cut, and capable of being split into very thin plates. These are much used in polarising apparatus (see POLARISATION). Selenite is a comparatively common mineral, although it rarely occurs in large quantities. Finely crystallised specimens are found at Bex in Switzerland, in Sicily, and at different places in the United States. There is a magnificent group of crystals of this mineral in the British Museum from Reinhardsbrunn in Gotha. In Nova Scotia, where, in the vicinity of Oxford, near River Philip, there are vast deposits of gypsum (large quantities of which are sent to the United States), selenite is found abundantly. At Petitcodiac, New Brunswick, where extensive deposits of gypsum also occur, there is a vein of nearly pure selenite one mile long and eight feet wide. Selenite, being a pure form of gypsum, is used for making the finest kind of plaster of Paris. Plates of selenite are said to have been used by the ancients for some of the purposes for which we use glass.

Selenium (sym. Se; at. wt. 79) is an element having two forms. In the *vitreous* form, at ordinary temperatures, it is a solid of a dark-brown colour, and when broken presents a conchoidal vitreous fracture; thin splinters of it are, however, of a dark-red tint when seen by transmitted light. It is tasteless and inodorous, a non-conductor of electricity. Its specific gravity is 4·28; its melting-point is 217° C., and its boiling-point 700° C. When selenium is very slowly cooled from the fused condition its appearance is quite different; the structure being *granular* or *crystalline* (sometimes called 'metallic'). Crystalline selenium is of a dull leaden colour; it is very opaque to light even in thin films; its specific gravity is 4·8, its melting-point 200° C., and its boiling-point 680° C. It is a conductor of electricity at ordinary temperatures. Its resistance to the passage of an electric current diminishes up to the point of fusion, but suddenly increases as the selenium becomes liquid. Another property of crystalline selenium, which has recently given it a new interest, is that it is remarkably sensitive to light; and its electrical resistance varies very much according to its exposure to light, being much less in the light than in the dark. It was in virtue of this property that the experiments were made which led in 1880 to the discovery of the Photophone (q.v.). The vapour of selenium is inodorous and deep yellow; it is 164 times as heavy as hydrogen at 1400° C.; this corresponds nearly to the molecular formula Se_2. When heated in the air selenium does not very readily take fire; but it is combustible, and burns with a blue flame, while a portion of it is volatilised in red fumes. The products of combustion are oxide of selenium and selenious anhydride, SeO_2.

Selenium is of rare occurrence in nature; it is chiefly found as a selenide in combination with lead, silver, copper, or iron; but it has also been discovered in sulphur, and in certain sulphides of iron. It forms with oxygen a suboxide and a binoxide (SeO_2, selenious anhydride); and as it forms also a selenic acid, $H_2SeO_4 + x$ aq, the existence of a selenic anhydride SeO_3 is inferred, though it has not been isolated. With hydrogen selenium forms seleniuretted hydrogen, or hydroselenic acid, H_2Se. Selenium was discovered in 1817 by Berzelius, in the refuse of a sulphuric-acid manufactory. He named it selenium (Gr. *selēnē*, 'the moon'), because in many respects it resembled tellurium (from Lat. *tellus*, 'the earth').

Seleucia, the name of several ancient cities in Syria, Pisidia, Pamphylia, Cilicia, Caria, and Mesopotamia, founded during the earlier existence of the dynasty of the Seleucidæ (q.v.). Of these two were especially distinguished. (1) SELEUCIA PIERIA, founded by Seleucus Nicator, a few miles north of the mouth of the Orontes in Syria, was the seaport of Antioch, and became of great importance during the wars between the Seleucidæ and the Ptolemies for the possession of Syria. It rapidly declined under the Roman dominion. The ruins have been fully explored and described in modern times by Pococke (*Observations on Syria*) and Chesney (*Royal Geographical Society's Journal*, vol. viii.). The remarkable tunnel of 1088 yards in length, which was excavated out of the solid rock and formed the only communication between the city and the sea, and the remains of its triple line of walls, citadel, temples, amphitheatre, necropolis, &c. attest the former importance and splendour of the city. (2) SELEUCIA ON THE TIGRIS was also built by Seleucus Nicator, on the west bank of the Tigris, 40 miles (according to Strabo 33) north-east of Babylon, which was despoiled to supply materials for the construction of the new city. Situated in a district of great fertility, and commanding the chief trading routes of Assyria, Babylonia, and western Persia, it rapidly rose to wealth and splendour, supplanted Babylon as the capital of the eastern portion of the Seleucid monarchy, and when in the acme of its greatness contained a population of more than 600,000. When the Seleucid empire fell before the Romans the fate of Seleucia was sealed. It was partly burned by Trajan (116 A.D.), and in 165 was completely destroyed by Avidius Cassius.

Seleucidæ, the dynasty of kings to whom fell that portion of Alexander the Great's Asiatic conquests which included Syria, a large portion of Asia Minor, and the whole of the eastern provinces (Persia, Bactria, &c.). The founder of the dynasty was SELEUCUS I., surnamed Nicator, who in the second partition of Alexander the Great's empire obtained Babylonia, to which, with the aid of Antigonus, he subsequently added Susiana; but a quarrel having arisen with that powerful chief, Seleucus took refuge in Egypt (316 B.C.). The course of events, however, allowed him to return to his satrapy in 312; his re-entry into Babylon marked the beginning of the *era of the Seleucidæ.* Having recovered Susiana, he conquered Media, and extended his power to the Oxus and Indus. In 306 he assumed the regal title; and four years afterwards he joined the confederacy of Ptolemy, Lysimachus, and Cassander against Antigonus, and obtained the largest share in the conquered territories of that ruler, a great part of Asia Minor and the whole of Syria falling to him. Towards the close of his reign he gained by war the rest of Asia Minor, but was assassinated (280) by one of his own officers. Seleucus cherished the ambition of building up a second empire equal in extent to Alexander's, and he pursued with great zeal the plan of 'Hellenising' the East, by founding numerous Greek and Macedonian colonies in various parts of his dominions; he also built numerous cities, several of which—as Antioch in Syria and Seleucia on the Tigris—rose to be among the most populous and wealthy in the world. In the reign of his feeble grandson, ANTIOCHUS II. (260-246), Bactria was lost and the foundations were laid of the kingdom of Parthia. His son, SELEUCUS II. (246-226), surnamed Callinicus, was greatly beset by Ptolemy of Egypt, by his own brother, and by the Parthian prince, but managed to hold his own with some difficulty. The glories of Seleucus I. were revived in the second son of Seleucus II., ANTIOCHUS III. (q.v.), 'the Great,' who was the first of the Eastern 'great kings' of Iran to come into collision with the Romans. His second successor was his own able son, ANTIOCHUS IV. (q.v.), Epiphanes (I.; 'the Illustrious'), who conquered Cœle-Syria and Palestine from the Egyptians, but withheld his hand from Egypt at the bidding of the Romans. He practised atrocious cruelties on the Jews, whose religion he endeavoured to root out in favour of the Greek religion; but the heroic resistance of the Maccabees (q.v.) completely foiled his project. He died in a state of raving madness, which was attributed by his subjects to his sacrilegious crimes, and so they in derision converted his surname into Epimanes ('the Madman').—The succeeding rulers were for the most part a set of feeble and incompetent sceptre-holders, none of whom was able to delay the gradual disintegration of the empire. Babylonia, the original centre of their power, was conquered by the Parthians in the reign of Demetrius II. (146-125). From that time the Seleucidæ were restricted to Syria, until that region was taken from them by Ptolemy and converted into a Roman province (65 B.C.).

Self-defence. See ASSAULT, MANSLAUGHTER.

Self-denying Ordinance, a measure carried through parliament in 1645 by the influence of Cromwell and the Independents, by means of which generals who were either less efficient or but half-hearted in the cause were removed from the command of the army. After Manchester's lack of energy at the second battle of Newbury (October 27, 1645) Cromwell had determined upon a change of tactics, and attacked Manchester in parliament, but he soon found the more sweeping measure a better means towards his ends. The Lords threw out the measure, whereupon the Commons proceeded to form a New Model Army under Sir Thomas Fairfax as general-in-chief. The Lords now passed the measure with some alterations and called on all existing officers to resign. Thus Essex, Waller, and Manchester were got rid of, while Cromwell was specially reappointed to the command of the cavalry as lieutenant-general.—For a similar measure, but one suicidal to good government, in the history of the French Revolution, see MIRABEAU, and ROBESPIERRE.

Selim I., Sultan of Turkey, son of Bajazet II., was born in 1467, and dethroned his father by the aid of the Janizaries, 25th April 1512. Then he caused his father, brothers, and nephews to be put to death. This gives the key to his character—warlike, energetic, unscrupulous, and fanatical. In 1514, after massacring 40,000 Shiites, he declared war against Shah Ismail of Persia, whom he defeated at Chaldiran in the neighbourhood of Tabriz; but a spirit of disaffection breaking out in his army, he was compelled to content himself with this success, which gave him possession of the provinces of Diarbekir and Kurdistan. In 1517 he conquered the Mameluke rulers of Egypt, and annexed that country, Syria, and the Hejaz. Moreover he won from the Abbaside calif, then living as a spiritual prince at Cairo, the headship of the Mohammedan world, the title of imam, and the standard of the

Prophet, and gained possession of the sacred cities of Mecca and Medina. He also laid the foundation of a regular marine, constructed the arsenal of Pera, chastised the insolence of the Janizaries with savage severity, and laboured to ameliorate, by improved institutions, the condition of the various peoples he had conquered. He died 22d September 1520, while planning an expedition against Rhodes. Strange to say, this savage fanatic was a lover of literature, and even himself cultivated the poetic art. He was succeeded by his son, Soliman (q.v.) the Magnificent. For other sultans named Selim, see TURKEY.

Selinus, an ancient Greek colony in the western end of Sicily, now represented by ruins close to the modern Castelvetrano. It was founded by Dorians about 628 B.C., conquered by the Carthaginians in 409, and utterly destroyed by them in 249, the inhabitants being deported. The most notable ruins still extant are six great Doric temples.

Seljuks, a division of the Ghuzz confederacy of the Turkish tribes, who were settled on the Jaxartes and in Transoxiana in the 11th century, when they became converts to Islam. Togrul Beg, grandson of a chief named Seljuk (whence the name of the several successive dynasties), severely crippled the empire of Ghazni (1040), and then turning westwards conquered all Persia. Ten years later he marched upon Bagdad, to the assistance of the Abbaside Calif (q.v.), a mere *fainéant* sovereign, who existed by the favour and protection of a powerful family of the Shiite faith. The head of this family (the Bowides) was, however, the master rather than the protector of the calif. Him Togrul seized and supplanted; and, being of the orthodox Sunnite faith, he was nominated by the calif 'Commander of the Faithful.' Dying in 1063, Togrul was succeeded by his nephew Alp-Arslan. This sovereign wrested Syria and Palestine from the rival Fatimite calif of Egypt, and in 1071 defeated the Byzantine emperor Romanus Diogenes, and captured him. The price of his release was a heavy ransom and the cession of great part of Anatolia or Asia Minor to the Seljuk. Alp-Arslan was stabbed by a captive enemy in distant Turkestan (1072), and was succeeded by his son Malik Shah. His reign is chiefly remarkable for the enlightened rule of his grand-vizier, Nizam ul-Mulk, the schoolfellow of Omar Khayyam (q.v.), the poet, and of Hassan ibn Sabbah, the founder of the Assassins (q.v.). This statesman founded a university at Bagdad, an observatory, and numerous schools and mosques, and with the help of his old friend Omar Khayyam revised the astronomical tables and introduced a new era, the Jelalian. After the death of Malik (1092) the extensive empire began to break up into smaller kingdoms. But already during his lifetime, and even that of his predecessors, powerful tributary princes had ruled over separate provinces in Syria (see NUR ED-DIN and SALADIN), in Kerman (beside the Persian Gulf), and in Asia Minor. During the first half of the 12th century the most powerful of these provincial rulers was Sinjar, who governed Khorassan, with Merv for his capital. He spent his life fighting against the Ghaznevids, against the Turkestan chiefs, and latterly against the Mongols. But a stronger and more immediate interest attaches to the province of Syria and that of Asia Minor, or Rum, as the Seljuks preferred to call it. It was the rulers of these two provinces or kingdoms who persecuted the Christian pilgrims and so provoked the Crusades (q.v.), and it was the rulers of the same two kingdoms against whom the crusaders of Europe principally fought. The capital of Rum was fixed at Iconium (Konieh) in the first half of the 12th century. This dynasty reached the acme of its power under Kaikavus (1211-34), who ruled over nearly the whole of Asia Minor and extensive territories in Mesopotamia and northern Persia. During the reign of his son Kaikhosrau II. the poet Jelal-ed-Din Rumi flourished and the various orders of dervishes arose; and at the same time the Mongols began to threaten the eastern borders of the state. Indeed from about 1243 the real sovereign power of that part of Asia was in the hands of the Mongol chiefs, Hulagu and his successors, until the rise of the Ottoman princes. These last, Turks like the Seljuks, had retreated westwards before the all-conquering Mongols about the middle of the 13th century, and at the end of it they entered the service of the Seljuk ruler of Asia Minor. After that the name Osmanli or Ottoman soon superseded that of Seljuk as the appellative of the Turkish rulers and ruling classes in Asia Minor. And out of the Ottoman supremacy grew the empire of Turkey (q.v.). The Seljuks, however, had centuries before, whilst they were still settled in Transoxiana, lost a good many of their peculiarly Turkish characteristics and had become 'Turkomans,' i.e. 'Like the Turks;' and with their conversion to Islam they also adopted the Perso-Arabian civilisation and customs, though still retaining their own language as well as using those of the peoples they had conquered.

See De Guignes, *Histoire des Huns*, &c. (4 vols. 1756-58), and the German translation (by Vullers, 1838) of Mirkhond's Persian *History of the Seljuks*.

Selkirk, a Scottish royal burgh, the county town of Selkirkshire, on an eminence 400 to 619 feet high, that flanks the right bank of Ettrick Water, 6¼ miles S. by W. of Galashiels by a branch-line (1856) and 40 SSE. of Edinburgh. The county buildings (1870), the town-hall (1803), with a spire 110 feet high, and the statues of Scott (1839) and Mungo Park (1859) are the chief features of the place, with the beautiful grounds of the Haining House. The 'souters of Selkirk' were long famous for their 'single-soled shoon;' but to-day the staple manufacture is that of tweeds, which dates from 1835. With Hawick and Galashiels Selkirk returns one member since 1868. Pop. (1831) 1880; (1861) 3695; (1891) 5788. About 1113 Earl David founded at *Schelechyrch* ('kirk of the shiels') a Tironensian abbey, which as David I. he removed about 1126 to Kelso (q.v.). The story of the eighty Selkirk men who marched to Flodden (1513), but of whom one only returned, bringing a captured pennon, dates, according to Mr Craig-Brown, only from 1722. Mr Andrew Lang is a native.

Selkirk, ALEXANDER. See JUAN FERNANDEZ.

Selkirk, EARL OF. See DOUGLAS, MANITOBA.

Selkirk Mountains, an outlying range of the Rocky Mountains, in British Columbia, extending southwards from about 52° N. lat. to near the United States frontier. The range contains enormous glaciers, and is the home of bears, bighorn sheep, the Rocky Mountain sheep, &c. One pass-valley (Rogers') has been reserved as a national park. The Canadian Pacific Railway climbs over the mountains at a point 4300 feet above the sea. See W. S. Green, *Among the Selkirk Glaciers* (1890), who describes what he saw of the range as 'a perfect Alpine paradise.'

Selkirkshire, an inland county in the south of Scotland, bounded by Peebles, Edinburgh, Roxburgh, and Dumfries shires. Measuring 28 miles by 17, it has an area of 260 sq. m. or 166,524 acres, of which barely one-seventh is under crops. Silurian in formation, and drained by Ettrick and Yarrow Waters to the Tweed, it is a pastoral region, of grassy rounded hills—Minchmoor (1856 feet), Dun Rig (2433, the highest), Ettrick Pen

(2269), and eight others exceeding 2000 feet above sea-level. Sheep-farming (over 160,000 head) is an important industry; and the manufactures are confined to the two towns of Selkirk and Galashiels. The Duke of Buccleuch is chief proprietor, holding about three-fifths of the whole county. Since 1867 Selkirkshire has united with Peeblesshire to return one member. Pop. (1801) 5388; (1851) 9809; (1871) 14,005; (1891) 27,349, of whom 5788 were in Selkirk, and 17,249 in Galashiels. Smaller than Middlesex, and than all but six of the thirty-three Scotch counties, Selkirkshire yet contains within its narrow bounds almost all the old Forest of Ettrick; St Mary's Loch; the whole course of the Yarrow; the vale of Ettrick, where the 'Shepherd' was born and lies buried; the birthplaces, too, of Laidlaw and Mungo Park, of the 'Flower of Yarrow' and Alison Cockburn; Ashiesteel, where Scott wrote *Marmion;* the scenes of the ballads of 'The Douglas Tragedy,' 'The Dowie Dens,' 'The Outlaw Murray,' and 'Young Tamlane;' the battlefield of Philiphaugh; and the ruins or sites of the castles and peel-towers of Newark, Dryhope, Tushielaw, Oakwood, and Buccleuch. See the articles ETTRICK, YARROW, PHILIPHAUGH; and T. Craig-Brown's *History of Selkirkshire* (2 vols. 1886).

Sellar, WILLIAM YOUNG, was born at Morvich near Golspie in Sutherland, February 22, 1825, and educated at Edinburgh Academy, of which at fourteen he was head-boy. He next went to Glasgow University, from which he passed at seventeen, a Snell Exhibitioner, to Balliol College, Oxford. He graduated with a classical first-class, in 1850 was elected to a fellowship at Oriel, next acted as assistant-professor at Durham, Glasgow (1851-53), and St Andrews (1853-59), filled for six years the Greek chair at St Andrews, and was elected in 1863 to the Latin chair at Edinburgh, which he retained till his death near Dalry in Galloway, 12th October 1890. He made his name widely known by his learned and brilliant book, *The Roman Poets of the Republic* (1863; revised and enlarged, 1881), which was followed by *The Roman Poets of the Augustan Age—Virgil* (1877), and *Horace and the Elegiac Poets* (1892), the latter edited from his papers by his nephew, Mr Andrew Lang, with a brief memoir prefixed. Of the last volume—the completion of his task—the part treating of Ovid alone is unfinished. The whole forms a noble *corpus* of criticism on the greatest poets of Rome, marked by full knowledge, insight at once keen and sympathetic, and a fine dignity of style—a quality in modern days too rare.

Selma, capital of Dallas county, Alabama, on the Alabama River, and at the intersection of a number of railways, 165 miles by rail NNE. of Mobile. It has a large trade in cotton, and possesses ironworks, cotton-factories, steam planing-mills, car-works, &c. Pop. (1890) 7626.

Selsey, or SELSEA, a village of 900 inhabitants, on a flat and dreary but fertile peninsula on the Sussex coast, 7 miles S. of Chichester. Here in the middle of the 7th century the cathedral church of the South Saxons was founded by Wilfrid of York; and Selsey was the see of a succession of twenty-two bishops, till in 1079 the seat of the bishopric was transferred to Chichester by Bishop Stigand. The sea has made great encroachments on the peninsula, which ends in Selsey Bill; and the site of the old cathedral is now submerged.

Seltzer Water (Ger. *selterwasser*) takes its name from the village of Nieder-Selters near Limburg, in the Prussian district of Wiesbaden, where several springs, in one basin, yield 5000 cubic feet an hour of this sparkling and effervescing mineral water. Its chief ingredients are carbonic acid, bicarbonate of sodium, and common salt. It acts as a mild stimulant of the mucous membranes and as a diuretic, and is applied in chronic disorders of the digestive, respiratory, and urinary organs. It is much used as a beverage and as a table-water by those suffering from liver complaint, and in hot climates and seasons. Some three million jars or bottles of this famous water are exported yearly to all quarters of the world. The spring was discovered early in the 16th century, but was at first little prized. Artificial Seltzer Water is extensively manufactured both on a large scale and for domestic use. See AERATED WATERS, MINERAL WATERS.

Selwyn, GEORGE, wit, was born of a good old Gloucestershire family on 11th August 1719, and was educated at Eton and Hertford College, Oxford, whence, after making the grand tour, he was expelled in 1745 for a blasphemous travesty of the Eucharist. He entered parliament for a pocket borough in 1747, and, siding generally with the court party, was rewarded with several sinecures; in 1751 succeeded his father in the Matson property; and for the best part of half a century led the life of a man about town, dozing in the House, gaming pretty deeply, corresponding much, and haunting executions. He often visited Paris, where he had the *entrée* of the best and the highest society, whilst at home his chief intimates were the Duke of Queensberry, Horace Walpole, 'Gilly' Williams, and Lord Carlisle. Grown at last 'like the waxwork figure of a corpse,' he died penitent at his house in Cleveland Row, London, on 25th January 1791. He left £33,000 to Maria Fagniani, and the residue of his fortune to 'Old Q,' who disputed with him the paternity of that future Marchioness of Hertford.

See Jesse's delightful *George Selwyn and his Contemporaries* (4 vols. 1843), and the review thereof in Hayward's *Lord Chesterfield and George Selwyn* (1854).

Selwyn, GEORGE AUGUSTUS, bishop, was born 5th April 1809. He was educated at Eton and at Cambridge. He rowed in the first inter-university boat-race (1829), and was a great pedestrian and swimmer, athletic powers found very serviceable in after life. In 1841, while curate of Windsor, he was consecrated first and only bishop of New Zealand and Melanesia—now divided into seven sees. On the voyage out he studied Maori and navigation, so that he could preach to the natives in their own tongue on his arrival, and could steer his own vessel on his missionary voyages. He visited every portion of his huge diocese before setting about his great work of organising it. A visit to England in 1854 brought back John Coleridge Patteson, afterwards the martyred bishop of Melanesia, to whose see Bishop Selwyn's second son was consecrated in 1877. In 1867 Bishop Selwyn attended the first Pan-Anglican Synod at Lambeth, and against his own inclinations was appointed Bishop of Lichfield—the see of the Black Country—where upon his initiative the first Diocesan Conference in which the laity were duly represented met in 1868, and where he died 11th April 1878. A devoted churchman, with love to God and loyalty to his sovereign and his archbishop as his guiding principles, he thought no duty too humble, no act of kindness too trifling, and no work to which he was sent too difficult to undertake. Possessing in a special degree the gift of organisation, and always regarding himself as 'a man under authority,' he expected the same soldier-like obedience from those under him. He did much to make Lichfield the life-giving, spiritual heart of the diocese, and so fulfil his high ideal of the cathedral system.

See Life by Rev. H. W. Tucker (2 vols. 1879) and (more popular) Life by Rev. G. H. Curteis (1 vol. 1889). For Selwyn College, see CAMBRIDGE, Vol. II. p. 670.

Semaphore (from *sēma*, 'a sign,' and *pherō*, 'I bear') was the name applied to the system of telegraphy in use before the application of the electric current. Semaphores were invented by Richard Lovell Edgeworth in 1767 (cf. p. 91 of his *Memoirs*, ed. 1854), but were first regularly established by the French in 1794 as a plan for conveying intelligence from the capital to the armies on the frontier. In the following year Lord George Murray introduced them in England; and by their means the Board of Admiralty were placed within a few minutes of Deal, Portsmouth, or Plymouth. These semaphores consisted of towers built at intervals of from 5 to 10 miles on commanding sites. On the top of each tower was the telegraph apparatus, which at first comprised six shutters arranged in two frames, by the opening and shutting of which in various combinations sixty-three distinct signals could be formed. In 1816 Sir Home Popham substituted a mast with two arms similar to many of the present railway signals. The arms were worked from within the tower by winches in the lookout room, where a powerful telescope in either direction constantly commanded the mast of the next station. If a fog set in at any point on the route the message was delayed; otherwise when a sharp lookout was kept the transmission was very rapid. For instance, the hour of one by Greenwich time was always communicated to Portsmouth when the ball fell at Greenwich; the semaphores were ready for the message, and it commonly passed from London to Portsmouth and the acknowledgment back to London within three-quarters of a minute. Each station was in the charge of a naval officer—usually a lieutenant—with one or two men under him. To save the cost of this establishment the Deal and Plymouth lines fell into disuse soon after the peace of 1815; and the superior advantages of the electric telegraph being incontestable, the Portsmouth line sent its last message on the 31st December 1847, and in this capacity the semaphore closed its career of usefulness for ever. Railway signals are, however, a form of semaphore. See RAILWAYS, p. 558, and, for the semaphore used for communicating with ships, SIGNALLING.

Semecarpus, a genus of polypetalous trees, of which the *S. Anacardium* is the Marking-nut Tree of India, a deciduous tree growing in the sub-Himalayan tract. An ink much used in that country for marking cotton cloths is obtained from the acrid juice of the pericarp of the fruit. Lime-water is added to improve the ink. The fleshy cup of the ripe fruit is eaten raw, but it is better when roasted. Bird-lime is made of the fruit in its green state. The wood also contains an acrid juice which causes swelling and irritation, in consequence of which the timber is not put to any use.

Semele. See DIONYSUS.

Semendria, a fortress of Servia, stands on the right bank of the Danube, 26 miles SE. of Belgrade. Here the Turks defeated the Hungarians in 1411. The place was taken by storm by Prince Eugene in 1717. Pop. 6578.

Seminoles, a tribe of American Indians, originally (1750) a vagrant branch of the Creeks, whose name Seminole signifies 'wild' or 'wanderer.' In 1817 they joined with the Creeks and some negroes who had taken refuge with them, ravaged the white settlements in Georgia, plundering plantations, and carrying off slaves, whom they refused to surrender. General Jackson was sent to punish them, and his expedition hastened the negotiations which ended in the cession of Florida to the United States (1819). By a treaty of 1823 the Seminoles, who numbered some 4000, gave up most of their lands for an annuity, and agreed to return fugitive slaves; but in 1832, to satisfy the settlers, the chiefs were deluded into signing a treaty agreeing to the removal of the whole tribe west of the Mississippi. This treaty was repudiated by the tribe at the instigation of Osceola (q.v.), one of their chiefs; and a war commenced against a handful of savages which lasted seven years, and cost hundreds of lives and millions of dollars. In the end the remains of the tribe were removed to the Indian Territory, where (except some 200 who are still left in Florida and some few in Texas and Mexico) all the Seminoles are now settled; they number 3000, receive an annuity of $25,000, have eight churches, besides government schools, and are under the training of Presbyterian missionaries.

Semipalatinsk, a province of Asiatic Russia, stretching northwards from Lake Balkash to the provinces of Tobolsk and Tomsk. It embraces outliers of the great Altai and other lofty chains of central Asia, rising to 10,000 feet, and enclosing between them wide stretches of steppe-land. The principal river is the Irtish, which flows north-westwards to the Obi. The climate ranges between wide extremes, and the whole region is undergoing desiccation. Area, 183,145 sq. m.; pop. (1885) 574,132, mostly Kirghiz. The chief town, Semipalatinsk, standing on the right bank of the Irtish, is an important trading centre for that part of Asia. Pop. 17,820.

Semi-Pelagianism. See PELAGIUS.

Semiramis, wife of Ninus, mythical founder of Nineveh according to Ctesias and the Greek historians. A daughter of Derceto the fish-goddess, she was exposed in infancy, but miraculously fed by doves, then brought up by Simmas a shepherd, whose name she took. Onnes, one of the king's generals, charmed by her beauty, married her, but she won the heart of the king himself by her heroic capture of Bactra, whereupon her husband had the loyalty to make away with himself. Ninus soon died, leaving Semiramis to reign gloriously for forty-two years, conquering in Persia, Libya, Æthiopia, unsuccessful in India alone. At the end of this time she left the throne to her son Ninyas and disappeared, thereafter to be worshipped as a divinity. The story is most probably borrowed from some Median epic. The name of the mighty queen survived in place-names, and was familiarly attached to the great works of antiquity, as the hanging gardens of Babylon. Many things in her story, and such points of detail as her personal beauty and her voluptuousness, point to an identification with the great Assyrian goddess Astarte (q.v.). See Lenormant, *La Légende de Semiramis* (Brussels, 1873).—The Semiramis of the North was a name not inappropriately applied to Catharine II.

Semiretchinsk, a province of Asiatic Russia, having East Turkestan on the SE., Ferghana on the SW., and Lake Balkash on the N., is a mountainous region, being crossed from east to west by the Ala-tau and Thian-Shan Mountains, whose peaks run up to 16,000 feet. Between them lies the mountain-lake of Issyk-kul. In the north of the province there are level tracts, partly fertile, partly barren sand. The climate is temperate; earthquakes occur—e.g. at Vyernyi (pop. 11,584), the chief town. Area, 147,298 sq. m.; pop. (1887) 758,258, of whom 595,000 are Kirghiz and 44,000 Russians; they are mostly engaged in pastoral pursuits, rearing large herds of horses, camels, and sheep.

Semites, a convenient name given by J. G. Eichhorn in 1787 to a group of nations closely allied in language, religion, manners, and physical features, who are mostly represented in Genesis x. as descended from Shem, a son of Noah. Their habitat is Abyssinia, Arabia, Palestine, Phœnicia, Syria, and the countries of the Euphrates and Tigris. Into those lands, according to one theory which is supported by Lenormant and others, there had preceded them an immigration of Cushites of the Hamitic race, who, proceeding from central Asia, occupied not only the lands that afterwards became Semitic, but also the Nile valley. Their Hamitic language and civilisation the Semites are said to have adopted. In language the Semites do show some affinity with the Berbers and the inhabitants of the Nile valley, and Genesis x. does, for political and geographical or other reasons, distribute the sons of Ham and Shem in a peculiar manner. But the increasingly prevalent theory is that not less than 4000 years B.C. the Semites migrated as nomadic tribes, probably from Arabia, into Mesopotamia. There they found a Turanian population dwelling in cities built of brick, under the regular government of priest-kings, skilled in the use of metals, using the cuneiform mode of writing, and comparatively far advanced in literature and culture. The hold of the Semites upon Shumir, the lower, more fertile, and more thickly inhabited part of the Euphrates valley, was not at first so strong as upon Accad, the upper part. In 3800 B.C. the Semitic adventurer Sharrukin usurped the kingdom of Accad. In Elam also the Turanian population was early overpowered by the intruding Semites, who came to form the upper strata of society. In 2280 B.C. the Semite Khudur-Nankhundi of Elam invaded and conquered Shumir and Accad, founding the Elamite line of princes; and about 2200 B.C. one of his successors, Khudur-Lagamar (Chederlaomer), carried his conquests as far as Palestine (see Genesis xiv.). These painful and oppressive impulses, and probably others like them, seem to have occasioned emigrations of many Semites. Some proceeded towards the north-west, reached the Mediterranean Sea, founded Sidon, Tyre, and other cities, and became known afterwards as Canaanites or Phœnicians. Later from Ur went others in the same direction, settled behind the Phœnicians, and were afterwards known as Israel. Others went northwards and built cities which developed into the empire of Assyria. While the Semites were in Mesopotamia they used the Turanian language in their public documents until they attained the ascendant in political power; and when afterwards they used their own language they continued to use the Turanian cuneiform mode of writing. The Turanian religion also was adopted by the Semites, and mixed with what religion their own primeval tribal religion or totemism had developed into. This amalgamation was consummated by Sharrukin II. of Accad about 2000 B.C.

The Semites as a race have a fine physical organisation, are mentally quick, clever, but not inclined to change, and not persistent in progress. They have been distinguished by a brilliant imagination and love of the beautiful; but have not shone in philosophy nor in science. Their literature has neither epic nor dramatic poetry worth notice. Almost their only arts are the sculpture of Assyria, the exquisite glass and pottery, and the textile fabrics and embroidery of the Phœnicians. Impatient of restraint, the Semites have not by political aptitude welded together themselves or others into large, compact, and enduring commonwealths. They have made their mark on the world in the Phœnician commerce, which visited even the Atlantic shores of Spain and France and drew tin from Britain; in the Phœnician colonies, which, dotting all the coasts and many islands of the Mediterranean Sea as far as Cadiz, and the coast of Asia as far as India, dispensed manufactures, improved primitive navigation, stimulated industry, trade, and ingenuity, and radiated the light of material civilisation; in the Carthaginian empire within Europe and Africa; in the exploits of Hannibal; in the dissemination of alphabetic writing, whereof the Phœnician form was the mother of the European and of most Asiatic alphabets, while the alphabet of the great Sabæan kingdom, or of the great and still more ancient Minæan kingdom in Arabia, is apparently the oldest of all alphabets hitherto discovered; in the Babylonian and Assyrian empires; in the Hebrew Bible and the Jewish religion; in the New Testament and the Christian religion; in the Koran and the Mohammedan religion; in the Mohammedan conquests and empire; and in the preservation of culture thereby during the dark and middle ages.

SEMITIC LANGUAGES, the languages spoken by the Semitic nations. One characteristic feature of them is triconsonantal roots from which by prefixed or affixed letters, but mostly by internal vowel changes, the other words are formed. Thus in Arabic *kătăbă* = 'he wrote,' *kâtib* = 'a scribe,' *kitâb* = 'a book,' *maktûb* = 'an epistle.' Another characteristic feature is that, though personal pronouns are affixed to nouns, verbs, and prepositions, there is an almost total absence of compound nouns, adjectives, and verbs. Thus, while in Arabic *beiti* = '*my* house,' *qatalahu* = 'he killed *him*,' *minhâ* = 'from *her*,' there are no such compound words as pro-motion, dread-ful, grati-fy. Other characteristic features are a verb with two tenses, and the simple structure of sentences, which are mainly formed by juxtaposition of clauses helped by *and*. Semitic languages have a much closer family likeness than the Indo-European, and show a large proportion of common words. The most highly developed, and on the whole the most characteristic, probably also the oldest of the group, is Arabic, which, with its ancient Sabæan and Minæan dialects of southern, western, and northern Arabia, and with Ethiopic, forms the southern division of Semitic languages, marked by the use of 'broken plurals,' in which the consonants of the singular are preserved, while the vowels are as much altered as possible. Thus from the Arabic *kitâb*, 'a book,' comes the plural *kŭtŭb*. Another mark is the universal use of *a* before the third radical letter of the active preterites; thus Arabic has *qâttala*, *aqtala*, for which Hebrew has *qittêl* and *hiqtîl*. Another mark is the distinction between the Arabic *sâd* and *dâd*, which are united in the Hebrew letter *tsâde*.—HEBREW, though a characteristically Semitic speech, shows many marks of linguistic decadence; ancient Hebrew is a more modern type of language than modern Arabic.—PHŒNICIAN differs little in grammar and dictionary from Hebrew. In the African territory of Carthage this language was spoken 400 years after the Christian era; a century before that era in Phœnicia itself it yielded to Aramæan or to Greek. Our only examples of it are a few corrupt sentences in the *Pœnulus* of Plautus, and inscriptions, most of which date from the 4th century B.C. or later, few belonging to the preceding three centuries.—MOABITIC, as the Moabite Stone of the 9th century B.C. shows, was Hebrew.—ARAMÆAN had its home in Aram of Damascus and Aram of Mesopotamia. It was the language of Assyria from early times, as we may see in 2 Kings xviii., and of Babylonia, even while Assyrian was used there for official purposes. It was the official language of the provinces of the Persian empire west from the Euphrates. Its western branch was the language of Palmyra and of the northern part of the Arabian kingdom of the Nabatheans, and is seen in the biblical books of Ezra and Daniel, where it has been erroneously named Chaldee. Later developments of this branch are the officially recognised Targums by Onkelos on the Pentateuch, and Jonathan on the Prophets, which were finally edited and fixed in the 4th or 5th century A.D in Babylonia. Somewhat later are some Midrashes, the Jerusalem Targums, and the Jerusalem Talmud. Of the 4th or 5th century are Palestinian translations of the Gospel.—SAMARITAN is another branch of western Aramæan, written in a Hebrew alphabet older than the Captivity, and spoken about 432 B.C. by an Aramæan people with Israelitish blood in them, who were desirous of conforming in speech as in religion to the Hebrew usage of northern Palestine. Arabic soon expelled western Aramæan after the Mohammedan conquest, though a faint echo of it still lingers in the Anti-Libanus. The Babylonian Talmud shows the common eastern Aramæan of Babylonia from the 4th to the 6th century. The language of the Mandæan sect resembles it. In the 2d century the Edessan dialect of Aramæan, which we call SYRIAC, began to be the language of eastern Christendom for all purposes; but for popular use it was slowly supplanted by Arabic after the Mohammedan conquest, becoming a dead and almost entirely ecclesiastical language. In the mountain regions of ancient Assyria Aramæan is still represented by several local dialects among Christians and even Jews.—ASSYRIAN, so called by us moderns because discovered by us in Assyria, is more correctly named BABYLONIAN. It is written in the difficult, cumbrous, and inadequate cuneiform character received from the Turanian natives. It shows scarcely any sign of a preterite tense. In popular use it early gave way to Aramæan.—ETHIOPIC, a sister tongue to Arabic, in some respects resembles more closely Hebrew and Aramæan even in the most ancient form of the language known to us.

For more detailed information as to the several Semitic peoples and their languages and literatures, see ALPHABET, ARABIA, ASSYRIA, CARTHAGE, ETHIOPIA, HEBREW LANGUAGE, JEWS, PHŒNICIA; MOHAMMED, KORAN, CALIF, &c. Semitic scholars are Gesenius, Ewald, Halévy, Furst, Lane, Dozy, J. de Goeje, Dillmann, P. de Lagarde, Land, Delitzsch, Haupt, Strassmaier, Menant, Oppert, George Smith, Rawlinson, Lenormant, Chwolsohn, Renan, Nöldeke, Hommel, Fleischer, Rodiger, A. B. Davidson, Robertson Smith, Wright, Payne Smith, Badger, Sayce, Salmoné, Wustenfeld, Socin, Kautsch, Böttcher, Petermann, Nestle, W. H. Green, Driver, Cheyne, Schrader, Schroder, Wellhausen, Baethgen. The 'Records of the Past' give many valuable translations of ancient writings. See Wright's *Comparative Grammar of the Semitic Languages*, edited by Robertson Smith (1890).

Semler, JOHANN SALOMO, one of the most influential German theologians of the 18th century, was born 18th December 1725, at Saalfeld in Thuringia, and educated at Halle. After editing for a year the Coburg official *Gazette,* and lecturing on philology and history at Altdorf for six months, he was in 1752 appointed professor of Theology at Halle, where he taught with great success. He died at Halle on 14th March 1791. For many years he enjoyed a wonderful popularity as a teacher, and exercised so wide and profound an influence as pioneer of the historical method that he has been called the 'father of Biblical Criticism.' Yet, of course, he contributed little to the science; his chief merit is to have pointed out the way and indicated the right methods to those who came after. He was distinctively a rationalist, and one of the most influential in emancipating theology from the fetters of tradition. But he sincerely believed in revelation; and he lost favour through his opposition to the *Wolfenbüttel Fragments,* and his adverse criticism of the 'naturalism' or extreme rationalism of Bahrdt. Both friends and enemies found it difficult to reconcile his defence of revelation with his own critical freedom. In insisting on the distinction of the Jewish and Pauline types of Christianity he (possibly influenced by the deists Toland and Morgan) clearly anticipated a main position of the Tubingen school. As a thinker he was deficient in philosophical consistency and breadth of view; and as a writer he possessed no literary skill or grace. He wrote a vast number of books; but none is of much value at the present day. The more important were *Apparatus ad liberalem Veteris Testamenti Interpretationem* (Halle, 1773), *Abhandlung von freier Untersuchung des Kanons* (4 vols. 1771–75), *De Dæmoniacis* (1760), *Selecta Capita Historiæ Ecclesiasticæ* (3 vols. 1767–69).

See his own *Lebensbeschreibung* (1781-82); Schmid, *Theologie Semlers* (1858); Tholuck, in his *Vermischte Schriften*; and for the influence of the Deists, an article by David Patrick on 'English Forerunners of the Tubingen School' in the *Theological Review* for 1877.

Semliki, a river of equatorial Africa, flowing north-east into Albert Nyanza. It was discovered by Stanley in 1888.

Semlin (Hung. *Zimony*), a frontier town of Hungary, stands on a tongue of land at the junction of the Save and the Danube, on the right bank of the latter, opposite Belgrade. It contains the ruined castle of John Hunyady, who died here. The town is the great seat of the Turco-Austrian transit trade, and the principal quarantine station for travellers from the Balkan states. Pop. 11,836, mostly Servians. See Kinglake's *Eothen.*

Semmering, a mountain on the borders of Styria and Austria, 60 miles SW. of Vienna, and 4577 feet above the sea, over which the Vienna, Gratz, and Trieste Railway has been carried by a series of ingenious engineering contrivances. The railway, built in 1850-53 at a cost of £2,000,000, sweeps up the steep face of the mountain in many curves, and descends its southern slope, after having passed through 15 tunnels and numerous galleries, and crossed 16 viaducts. It extends from Gloggnitz on the north to Mürzzuschlag on the south, a distance of 25 miles, traversed by quick trains in 1 hour and 37 minutes; by slow in 2 hours 17 minutes. The greatest elevation is reached at 2940 feet in the Semmering tunnel (4692 feet long). The steepest gradient for any distance is 1 in 40.

Semmes, RAPHAEL (1809-77). See ALABAMA.

Semnopithe'cus, the genus of monkeys to which the Entellus Monkey (q.v.) belongs.

Semolina, an article of food consisting of granules of the floury part of wheat. The name semolina is often applied to the larger sizes of 'middlings' made in the process of flour-milling (see MILL), and these products are sometimes sold under the name semolina in the granular state after thorough cleaning, instead of being ground into flour. Semolina is chiefly used for making puddings and soups.

Sempach, a small town of Switzerland, 9 miles by rail NW. of Lucerne, on the east shore of the lake of Sempach. Under its walls Leopold, Duke of Austria, with 4000 men, was met on 9th July 1386 by the confederated Swiss to the number of 1500. The nature of the ground being unfitted for the action of cavalry, the horsemen (1400 in number) dismounted, and formed themselves into a solid and compact body, which was at once charged by the Lucerners; but the wall of steel was impenetrable, and not a man of the Austrians was even wounded, while many of the bravest of the Swiss fell. But, as the legend runs, Arnold von Winkelried, a knight of Unterwalden, seized with a noble inspiration, rushed forward, grasped with outstretched arms as many pikes as he could reach, buried them in his bosom, and bore them by his weight to the earth. His companions rushed over his body into the breach thus made, slaughtered the armour encumbered Austrian knights like sheep, and threw the remainder into the utmost confusion and dismay. The result was a decisive victory for the Swiss, who thus asserted their independence, and finally broke the efforts of the Austrian dukes to subdue them. The anniversary of this great victory is still celebrated by religious solemnities on the field of battle.

Semper, KARL, naturalist, was born at Altona on 6th July 1832, studied at Kiel, Hanover, and Würzburg, and, after travelling in the Philippines and South Sea Islands, became professor of Zoology at Würzburg. He has written on the Philippines, on several problems of comparative anatomy, and *The Natural Conditions of Existence as they affect Animal Life* (trans. 1880).

Sempervivum. See HOUSE-LEEK.

Sempringham. See GILBERTINES.

Sen, KESHUB CHUNDER, an Indian religious reformer, was born at the village of Garifa (Gouripore) in Bengal, on 19th November 1838, and received an education partly English, partly Hindu. About 1858 he was attracted by the Brahmo Somaj (q.v.), and soon afterwards began the work of his lifetime, a steady endeavour to promote the religious regeneration of his countrymen. In 1866 he founded the more liberal 'Brahmo Somaj of India.' After a visit to England in 1870 he organised in Calcutta several schemes of charitable philanthropy on the lines of what he had seen in England. In 1878 a schism broke out in his church, caused by his own autocratic temper, and by his leanings to mysticism. His last years were years of controversy, waning influence, and disappointment; and he died on 8th January 1884. See Max-Müller, *Biographical Essays* (1884).

Senaar. See SENNAAR.

Sénancour, ÉTIENNE PIVERT DE, author of *Obermann*, was born at Paris in November 1770. In a sickly and secluded boyhood he read eagerly, especially travels; at fifteen entered for four years the Collége de la Marche; and here devoured Malebranche, Helvétius, and the 18th-century philosophers, losing his faith completely in the process. At nineteen, with the connivance of his mother, he left home to escape the course at Saint Sulpice required by his imperious father, turned his steps to the lake of Geneva, the next year at Fribourg married a young girl who did not long survive, lost his patrimony through the Revolution, but returned to Paris about 1798, and thereafter made a modest living by his pen, eked out with a pension granted by Louis-Philippe on the recommendation of Thiers and Villemain. He died at Saint-Cloud in February 1846, asking that on his grave might be placed these words only: *Éternité, deviens mon asile.* His fame rests securely on three books: *Rêveries sur la Nature primitive de l'Homme* (1799), *Obermann* (1804), and *Libres Méditations d'un Solitaire Inconnu.* In the first book we see the student of Rousseau weighed down by the absorbing dogma of necessity, full of aversion for all human society, returning to his ideal in the patriarchal nomad, the vegetative instinct, and the primordial sensations of man. In *Obermann* his hero travels in the Valais, next to Fontainebleau, and again to Switzerland, writing his thoughts the while in letters to a friend. Here the atheism and dogmatic fatalism of the *Rêveries* have given place to universal doubt no less overwhelming. Nowhere is the desolating 'maladie du siècle' more effectively expressed than in this book, which, with affinities enough to Chateaubriand and Madame de Staël, is yet completely original in its inwardness, its sincerity, the delicate feeling for nature it exhibits, and the melancholy eloquence of many of its passages. 'Though he may be called a sentimental writer,' says Matthew Arnold, 'and though *Obermann*, a collection of letters from Switzerland treating almost entirely of nature and of the human soul, may be called a work of sentiment, Sénancour has a gravity and severity which distinguish him from all other writers of the sentimental school. The world is with him in his solitude far less than it is with them; of all writers he is the most perfectly isolated and the least attitudinising. His chief work, too, has a value and power of its own, apart from these merits of its author. The stir of all the main forces, by which modern life is and has been impelled, lives in the letters of *Obermann;* the dissolving agencies of the 18th century, the fiery storm of the French Revolution, the first faint promise and dawn of that new world which our own time is but now more fully bringing to light—all these are to be felt, almost to be touched, there. To me, indeed, it will always seem that the impressiveness of this production can hardly be rated too high.'

Sénancour was neglected in his day, but he has found fit audience in George Sand, Sainte-Beuve, and, amongst ourselves, Matthew Arnold, whose two elegies, *In Memory of the Author of Obermann* and *Obermann Once More*, are known to all lovers of English poetry.

See Sainte-Beuve's two essays in *Portraits Contemporains*, vol. i.; and the *Cornhill Magazine*, vol. xlv.

Senate, the deliberative assembly of the Roman people (see ROME, Vol. VIII. p. 789). In modern republics, as in France (q.v.) and the United States (q.v.), the senate is the upper chamber of the legislature. The governing body of universities usually is the senate (see UNIVERSITY).

Sendai, a town on the east coast of the mainland of Japan, 220 miles NNE. of Tokyo by rail. Pop. (1890) 90,231.

Seneca, Annæus Seneca (prænomen unknown), a Spaniard from Corduba (Cordova), was born about 54 B.C., and, having come to Rome as a youth, studied eloquence under Marillus. We next find him again in Spain, married to Helvia, by whom he had three sons—Novatus, Lucius Annæus, and Mela (father of Lucan the poet). About 3 A.D. he returned to the capital a second time to busy himself with rhetoric, till, under Tiberius, he sought his native country once more, and died there, 39 A.D. He was a great admirer of Cicero. With much of the antique Roman fibre, he had moral ballast enough to steer clear of the excesses on which contemporary rhetoricians made shipwreck. Besides a historical work, now lost, he wrote in later life *Oratorum et Rhetorum Sententiæ; Divisiones; Colores;* ten books of 'Controversiæ,' of which the first, second, seventh, ninth, and tenth are complete, the remainder surviving only in extracts; and one book of 'Suasoriæ'—the whole, fragmentary as they are, of high importance for the history of Roman rhetoric. The best edition is that of H. J. Müller (Prague, 1887), while Sander's *Sprachgebrauch des Rhetors Annæus Seneca* (1880) is of special value to the student of Latin style.

Seneca, L. ANNÆUS, son of the preceding, also a native of Corduba, was born about 4 B.C., and carefully educated for the bar, under his father's eye, in Rome, where, in Caligula's reign, he narrowly escaped the death to which that emperor, jealous of his enlightened liberalism, had destined him. After years of exclusive devotion to philosophy and rhetoric, he entered the Curia, but, 41 A.D., lost the favour he had won with Claudius by getting involved, through the emperor's infamous wife Messalina, in a state-trial which ended in his banishment to Corsica, whence he did not return till after an exile of eight years. Entrusted by Agrippina with the education of her son Nero, he acquired over the youth an influence as strong as it was salutary, and, having already at Agrippina's instance become prætor, he was, at that of Nero (now emperor), made consul, 57 A.D. His high moral aims and intellectual gifts, possibly through defect of the courtier's tact, gradually incurred the aversion of the rapidly deteriorating emperor, who at length came to regard him with jealousy and hatred. He has been taxed by imperial apologists, but unjustly, with vanity and ambition—more plausibly, perhaps, with love of wealth and the power it brings. His wealth, accumulated under Nero's profligate extravagance, excited, it is said, the rapacity of the emperor, whose sinister designs he anticipated by offering to refund it, with the exception of a pittance on which he proposed to retire. These overtures Nero rejected, whereupon, under pretence of illness, he withdrew from the public gaze. An attempt on Nero's part to poison him having failed, he was drawn into the Pisonian conspiracy, accused, convicted, and condemned. Left free to choose his mode of death, he elected to open his veins, and gradually succumbed to syncope, 65 A.D. His second wife, Pompeia Paullina, who wished to die with him, and actually had her own veins incised for the purpose, survived him a few years.

A noble, upright character, Seneca was yet the object of calumnious detraction—to such a degree that the utmost caution is necessary in passing judgment on him. In philosophy he inclined to the Stoic system, though not indisposed to engraft upon it the tenets of the Epicurean school. But his moral independence is an outstanding feature in his voluminous *dicta*, which, often profound, are always sharply and distinctly reflected in the steel-mirror of his style. Earnestness and self-abnegation are their most memorable note, especially in their inculcation of man's duty to himself and to his neighbour. The relations of his teaching to Christianity have recently evoked a number of treatises, attempting to prove his correspondence, if not personal association, with the apostle Paul, his contemporary in Rome. The points of divergence, however, between him and the teacher of the Gentiles are more numerous than the points of coincidence (see the Dissertation in Lightfoot's Com. on Philippians). His writings, apart from much that has been fathered on him, include three books *De Ira*; three consolatory pieces addressed to his mother Helvia, to Polybius, and to Marcia (*De Consolatione*); treatises *De Providentia*, *De Animi Tranquillitate*, *De Constantia Sapientis*, *De Clementia* (*ad Neronem Cæsarem*), *De Brevitate Vitæ* (*ad Paulinum*), *De Vita Beata* (*ad Gallionem*), *De Otio aut Secessu Sapientis*; seven books *De Beneficiis*; 124 *Epistulæ ad Lucilium*, comprising free speculations on philosophical questions of every kind, in which his characteristic powers appear to special advantage; a scathing satire on the Emperor Claudius, in the form of a parodied apotheosis (*Apocolocyntosis sive Ludus de Morte Cæsaris*); finally, seven books *Quæstionum Naturalium*, addressed to Lucilius the Younger—the only surviving Roman treatise on physics, if not the first in Latin literature (of the same compass at least). It reveals a decidedly exacter and wider knowledge and a sounder critical faculty than the later work of the elder Pliny.

Seneca had also a poetical side, if we may accept as his the epigrams (mainly referring to his banishment) and the eight tragedies (*Hercules Furens*, *Thyestes*, *Phædra*, *Œdipus*, *Troades*, *Medea*, *Agamemnon*, and *Hercules Œtæus*, along with two scenes from a *Thebais*) usually comprised among his *opera omnia*. These are imitations of Greek models, and are distinguished by great mastery of style, vigorous imagination, and keenness of psychological insight. But their purely rhetorical, eminently undramatic, character unfits them for the stage, if indeed they were ever intended for it. In versification they are 'correct' to a fault, till the monotony of their cadences becomes as wearisome as their declamatory strain.

Of editions of his prose writings that of Gronovius (1661-82), of Ruhkopf (1797-1811), and, best of all, that of Fickert (1842-45), still hold their place, while some of his special treatises have been carefully edited by Koch and Vahlen, and by Gertz. His tragedies may be most conveniently read in the editions of Gronovius (1661-81), of Schroder (1728), of Bothe (1819 and 1822), of Peiper and Richter (1867), and of Leo (1878); *Minor Dialogues*, translated by A. Stewart (1889). See also a paper by H. A. J. Munro on Peiper and Richter's edition in the *Journal of Philology*. A striking portrait of the philosopher-statesman at Nero's court, especially in relation to his assumed association with St Paul, is given in Mr Hugh Westbury's novel, *Acté* (1890).

Seneca Falls, a post-village of New York, on the Seneca River, 10 miles from the lake and 41 miles by rail WSW. of Syracuse. The river falls 50 feet here, and the place contains a number of mills, foundries, and manufactories of steam fire-engines, pumps, &c. Pop. 5880.

Seneca Lake, one of a range of narrow lakes in the western part of the state of New York. It is 36 miles from north to south, 2 miles in average width, and 530 feet deep. Steamboats ply daily from end to end.—For the Seneca Indians, from whom the lake takes its name, see IROQUOIS.—Senega (q.v.) is a form of the same word.—Seneca Oil is an old name for Petroleum (q.v.).

Senecio, the most numerous genus of the great natural order Compositæ, having a hairy pappus, a naked receptacle, and a cylindrical involucre of linear equal scales, with a few smaller scales at their base. The species are annual, perennial, and half-shrubby plants, natives chiefly of the temperate and cold parts of the world, the half-shrubby species being from the warmer latitudes. Eleven species are reckoned as British, and commonly known as Groundsel (q.v.) and Ragwort (q.v.). *S. Saracenicus*, probably not a true native of Britain but introduced in the middle ages, has undivided lanceolate leaves, and was once in repute as a vulnerary. The Fireweed of North America is *S. hieracifolius*. It receives its popular name from its appearing abundantly wherever a part of the forest has been consumed by fire. Many species of Senecio have a strong, disagreeable smell. A few are rather ornamental as flowers; see CINERARIA.

Senefelder, ALOYS. See LITHOGRAPHY.

Seneffe, or SENEF, a town in the province of Hainault, Belgium, 27 miles by rail S. by W. of Brussels, with a pop. of 3438, is the centre of a district in which manufactures of pottery and glass are extensively carried on, but is chiefly notable as the battlefield on which William of Orange (III. of England) was defeated after a bloody contest by the Great Condé, 11th August 1674. Here, too, on 2d July 1794 the French general Marceau defeated the Austrians.

Senega, or SNAKE ROOT, is the dried root of *Polygala Senega*, used as a cure for snake-bites in America. See MILKWORTS.

Senegal, a river of West Africa, has two main sources, the Bafing which flows north from the plateau of Futa-Jallon, and the Bakhoy which comes from the south-east, the country of Buré, not far from the north bank of the Joliba (Niger). These streams meet at Bafulabé, 700 miles from the coast, and from there the united Senegal flows north-west, west, and south-west, and reaches the Atlantic some 10 miles below St Louis. For three months of the year (July-October) boats drawing 20 feet can get up to Kayes, 40 miles below Bafulabé. The channel is, however, in those higher reaches greatly obstructed by falls and 'narrows,' and in its lower course it is studded with numerous low, flat islands. Although the river is navigable all the year round for about 200 miles up, it is not so serviceable to navigation as it might be because of a formidable bar that lies across its mouth. The difficulties of the navigation are in part overcome by a railway along the left bank of the river, between Kayes and Dioubéba, a place 25 miles beyond Bafulabé, and the French are continuing the line to Bammako on the Niger, which is only about 320 miles distant from Kayes.

Senegal, a French colony in West Africa, consisting of various posts, towns, and territories situated on both banks of the river Senegal, as St Louis, Dagana, Médine, Bafulabé, &c. The population does not exceed 135,500. The administrative districts of the colony are under a governor. For further particulars, see Senegambia.

Senegambia, a territory subject to France, situated on the west coast of Africa and embracing the colony of Senegal proper and various protected states, as Cayor and Salum (along the Atlantic), Damga, Bambuk, Bundu, and others lying between the Atlantic Ocean and the Senegal and Gambia rivers—the word 'Senegambia' (not used by the French) is compounded of the names of these two rivers. Until 1890 Senegambia included the region known as the 'Rivers of the South' (Casamance, Casini, Nunez, Pongo, and others), and certain districts on the Gold Coast; but at the date quoted the more southerly region (Rivières du Sud) was placed under a separate lieutenant-governor, who resides at Konakry on the Dubreka, and the Gold Coast districts were divided into two distinct and independent colonies, the Gold Coast districts and the Bight of Benin districts. On the other hand, farther north, the French claim the Atlantic coast southwards from Cape Blanco to the mouth of the Senegal; whilst inland they have extended their authority over Futa-Jallon, Beledugu, and Macina as far as the Joliba (Niger). These several protected states of the interior are generally called collectively the French Soudan, and are administered by an officer under the governor of Senegal. Moreover in virtue of recent treaties—e.g. with Great Britain in August 1890—the vast expanse of the Sahara south of Algiers and Tunis, right up to the Niger, and to a line drawn eastwards from Say on that river to Barruva on Lake Tsad, is recognised as being within the French 'sphere of influence;' and France is gradually feeling her way down the Niger to Timbuctoo. South of the Niger too she is beginning to establish herself, for in 1889 Captain Binger proclaimed in agreement with the native chiefs a protectorate over the Kong states, an immense area stretching almost down to the Gulf of Guinea, from 8° 30′ to 12° N. lat. Thus the territory claimed by France in this part of Africa extends from Tunis to Sokoto and the Gulf of Guinea, and from the Atlantic and the frontier of Morocco to Lake Tsad. The only interruptions to the continuity of this vast area are the British colonies of Gambia and Sierra Leone, Liberia, certain Portuguese territories of no great extent, and the numerous small colonies belonging to different European powers on the Guinea coast.

Of this gigantic territory France actually occupies little more than the colonies of Senegal, 'Rivers of the South,' and the two groups on the Gold Coast. These are estimated to have a total area of 165,000 sq. m. and a total pop. of 200,000. The people belong for the most part to the Peulh and Mandingo tribes of Negroes, and are in part Moslems, in part fetich-worshippers. The 'French Soudan' has an area of probably 50,000 sq. m. and an estimated pop. of nearly 300,000. The principal geographical feature in these united regions is the plateau (2000 to 4000 feet) of Futa-Jallon; from its valleys issue many rivers that flow (e.g. the Gambia) west and south-west to the Atlantic, north to the Senegal, and east and north-east to the Joliba (Niger). The villages of the natives are chiefly planted beside these various watercourses. Ground-nuts, gums, india-rubber, timber (including 'Senegal ebony;' see Dalbergia), and other wild products constitute the bulk of the exports, which reach an annual value of £662,000 (three-fourths to France). The imports (textiles, liquors, and food-stuffs) are valued at £1,120,000 (nearly half from France). St Louis (q.v.) is the principal town in these colonies. The French first settled in this part of Africa about the beginning of the 17th century; but the settlements (more than once captured by the English and again restored) languished until the appointment of General Faidherbe as governor in 1854. He began a most vigorous line of action, subdued the Berber chiefs who prevented the French advance inland, and annexed their territories. This policy was pursued in the same spirit by subsequent governors; districts were annexed and protectorates proclaimed with extraordinary celerity, though the two powerful chiefs Ahmadou and Samory occasioned them a great deal of trouble during the years 1887 to 1890.

See *Sénégal et Niger* (an official publication, Paris, 1884); Faidherbe, *Le Soudan Français* (Lille, 1881-85); *Annales Sénégalaises* (1886); and *Bull. Soc. de Géographie* (1891).

Seneschal (Old French; from the same roots as the Gothic *sins*, 'old,' and *skalks*, 'a servant;' compare *marshal*), a functionary in the household of the Frankish kings corresponding to what in England and Scotland was designed 'steward,' usually rendered into Latin as *senescallus*.

Senigallia. See Sinigaglia.

Senior, Nassau William, political economist and 'prince of interviewers,' was born on 26th September 1790, at Compton in Berkshire, the eldest son of the vicar of Durnford, Wilts, and from Eton passed to Magdalen College, Oxford, where in 1812 he took a distinguished first-class in classics. In 1819 he was called to the bar at Lincoln's Inn; during 1825-30, and again during 1847-62, was professor of Political Economy at Oxford; in 1832 was appointed a Poor-law commissioner; and from 1836 to 1853 was a Master in Chancery. He travelled much, and wrote much for the *Edinburgh Review* and other leading periodicals, his twenty works including, besides treatises on political economy, *Biographical Sketches* (1863); *Essays on Fiction* (1864); *Historical and Philosophical Essays* (1865); *Journals, Conversations, and Essays relating to Ireland* (1868); *Journals kept in France* (1871); *Conversations with Distinguished Persons during the Second Empire* (4 vols. 1878-80); and *Conversations and Journals in Egypt and Malta* (1882). He died 4th June 1864.

Senlac. See Hastings.

Senlis, a very ancient town of France, dept. of Oise, 33 miles NNE. of Paris. Its older portion is surrounded by walls, flanked with towers, which date from Roman times. The cathedral, a small edifice, with a striking bell tower, is a beautiful example of early Gothic (begun in 1155); Senlis ceased to be a bishop's seat in 1801. Here was signed on 23d May 1493 a treaty between Charles VIII. of France and the Emperor Maximilian I. There still exist the ruins of an old royal castle. Pop. 7111.

Senna is the dried leaflets of several species of Cassia, various preparations of which are used in medicine as purgatives. Two sorts are recognised in the British Pharmacopœia—viz. Alexandrian senna and Tinnivelly senna. The Alexandrian senna leaves are chiefly obtained from *Cassia acutifolia*, while the Tinnivelly senna leaves are yielded by *Cassia angustifolia*. *Alexandrian senna* is chiefly grown in Nubia and Upper Egypt, and is imported in large bales from Alexandria. It is often adulterated largely with the flowers, pods, and leaves of *Solenostemma Argel*. *Tinnivelly* or *East Indian senna* resembles Alexandrian senna in odour and taste. The leaflets are, however, larger and finer, 'about 2 inches long, lanceolate, acute, unequally oblique at the base, flexible, entire, green, without any admixture.' The rounder leaves of the *C. obovata* are also used in medicine, and are sometimes mixed with the other kinds.

Cassia obovata.

The active principle in senna is a glucoside, which has been named cathartic acid, and which is closely allied to chrysarobin and the purgative principle in rhubarb; there are also other substances which impart to senna its peculiar odour and taste, as well as a variety of sugar. The different pharmaceutical preparations of senna act as moderately active cathartics, but tend to cause griping. To obviate this, and to disguise the nauseous taste of the drug, they are all made up with a number of carminative and flavouring substances. The active principles in senna are excreted in the urine, which is coloured a deep yellow, and by the milk, which is rendered purgative. The officinal preparations comprise the *confection of senna* (dose 60 to 120 grains), the *infusion of senna* (dose 1 to 2 fluid oz.), the *syrup of senna* (dose 1 to 4 fluid drachms), the *tincture of senna* (dose 2 to 8 fluid drachms), and the *compound mixture of senna* or 'black draught' (dose 1 to 1½ fluid oz.). Compound liquorice powder consists largely of senna. The dose of senna itself is 10 to 30 grains.

BLADDER SENNA (*Colutea*) is a genus of shrubs of the natural order Leguminosæ, sub-order Papilionaceæ, having pinnated leaves, red or yellow flowers, and remarkably inflated pods, whence the English name. One species (*C. arborescens*) is common in shrubberies in Britain. It is a native of the south of Europe, and is found on the ascent of the crater of Mount Vesuvius—almost the only plant that exists there.

Sennaar (properly *Sennar*, sometimes also *Senaar*), a city of the Eastern Soudan, stands on the Blue Nile, about 160 miles SSE. of Khartoum. Pop. 8000. It is the chief town of a district lying between the Blue and the White Nile, which was made an Egyptian province in 1820, but fell to the Mahdi in 1884. An account of the disastrous expedition of Hicks Pasha into this province in 1883 will be found in Colonel the Hon. J. Colborne's book, *With Hicks Pasha in the Soudan* (1885), and in Major Wingate's *Mahdiism and the Egyptian Sudan* (1891).

Sennacherib, an Assyrian king, son of Sargon, reigned 702 to 681 B.C. The chief events of his reign are enumerated under Assyria (q.v.). He was the originator of great public works, as the embankment of the Tigris. the making of canals, watercourses, and the erection of a gigantic palace at Nineveh.

Senonian. See CRETACEOUS SYSTEM.

Sens, an old town of France, dept. Yonne, stands on the right bank of the Yonne, 70 miles by rail SE. of Paris, and is still surrounded with its ancient walls. Its principal ornament is the Gothic cathedral of St Stephen, built in 1122-68, but restored twice or thrice since. It has splendid portals, fine stained glass, and two large bells; in its treasury are preserved the vestments of Thomas à Becket. There are also the palace and ancient public offices of the archbishop, and a town museum. The chemist Thénard was born in the place. Pop. (1886) 13,958. See Vaudin, *Les Fastes de la Sénonie* (Paris, 1882).

Sensation may be defined as the change in consciousness which results from the transmission of nervous impulses to the brain. Such impulses may be generated within the nerves themselves (but only in diseased conditions), or may be produced by stimuli applied to such parts of the body as are provided with nerves. Such nerves are often styled sensory or afferent. It must be remembered, however, that afferent impulses are constantly being carried to the brain from all parts of the body, resulting in motor and other acts necessary to our life, without exciting any sensation at all. It is through our sensations that we gain our knowledge of the external world, and of the state of our body. The means by which these are produced are the elaborate nervous mechanisms developed in connection with the various senses of smell, sight, hearing, taste, touch, temperature (or heat and cold), pain or general sensibility, the muscular sense, and those of hunger and thirst. While we have obtained a certain amount of knowledge of the nature of a nervous impulse resulting in muscular movement, the same cannot be said of a sensory nervous impulse. We cannot measure the rate of its transmission along the nerve; we have absolutely no notion of the change, if it is legitimate to employ such a term, by which a sensory nervous impulse becomes transformed into a sensation; we as yet know imperfectly at what part of the brain this transformation takes place, or by what paths the sensory impulses travel towards the brain. It has long been known, however, that if the posterior division of the bundle of nerve fibres constituting that part of the cerebrum which is termed the internal capsule (see BRAIN) is destroyed a complete loss of sensation on the opposite side of the body results. This has led to the investigation of the posterior part of the cerebrum, to which these fibres more specially pass, for 'centres,' the destruction of which would involve loss of the various forms of sensibility. The results are as yet conflicting. It is generally agreed that the 'centre' for sight is in the inner side of the occipital lobe; but there is in the angular convolution another centre in which visual sensations probably undergo a further elaboration. Above the corpus callosum there lies a long convolution, the gyrus fornicatus, the removal of which produces complete loss of tactile sensibility of the opposite half of the body; but in the 'motor area' there are probably other centres, as this is rarely diseased without the production of peculiar modifications of sensation. The centre for hearing has been located in the upper convolution of the temporal lobe, that for smell and taste on the anterior end of the temporal lobe. An exhaustive consideration of the difficulties of the problem will be found in Foster's *Text-book of Physiology*.

Each of the special senses has its own peculiar end-organ: the special endings of the olfactory nerves in the upper part of the septum of the nose for that of smell; the retina in the eyeball for sight; the rods of Corti in the cochlea for hearing; the taste bulbs and the fibrils in the fungiform papillæ in the tongue for taste; and the Pacinian corpuscles and the special ramifications of the cutaneous nerves in the epidermis for touch. The integrity of these and of the special non-nervous apparatus with which they are connected is necessary for the production of a sensation. Thus, the transparent media of the eyeball, and the rods and cones of the retina are all essential to the production of a visual sensation. In proportion as they are abnormal, the sensation is imperfect. Further, each end-organ can be thrown into action only by certain kinds of stimuli, and the nerves in connection with them convey those impulses only which give rise to their own special varieties of sensation. The retina can only be stimulated by waves of light, never by those of sound, and the optic nerve if stimulated directly can give rise to visual sensations only. This law holds good also for the cutaneous nerves, there being reason to believe that the end-organs for touch are not the same as those for temperature. It is probable even that there are separate nerves for the perception of heat and of cold. All parts of the end-organs are not equally sensitive or capable of being similarly affected by the same kind of stimulus. Thus, the same substance may appear sweet at the anterior part and bitter at the posterior part of the tongue. The retina is most sensitive at the yellow spot, while the various colours are perceived over areas which differ considerably. Tactile sensibility varies exceedingly. The points of a compass can be felt as double at a distance of about $\frac{1}{25}$ part of an inch at the tip of the tongue, of $\frac{2}{25}$ of an inch on the front of the tip of the forefinger, but only at a distance of more than 2½ inches on the back.

The muscular sense is that by which we are made aware of the position of any part of the body, by which we gauge the amount of movement necessary to affect any object or to overcome any resistance. Many authorities deny the existence of such a special sense altogether, and believe that it is merely a form of ordinary tactile sense. But that this is not so is frequently illustrated in a disease of the spinal cord, locomotor ataxy, in which there is, when the eyes are shut, a more or less complete absence of knowledge of the position of the limbs and of the power of regulating their movements, although the cutaneous tactile sensibility may be quite normal. It would appear likely that the nerve endings connected with this sense are situated in the muscles, tendons, and joints, and that these are stimulated by changes in movement and mutual pressure in these structures.

The sensation of pain (or general sensibility) is produced when pressure on a part, or when the temperature of a body applied, exceeds certain limits. What was at first a sensation of touch, or of heat or cold, becomes replaced by a painful sensation. It is very difficult to be certain whether there are special end-organs for the reception of such impressions. It is quite beyond doubt that the olfactory, optic, auditory, and gustatory nerves do not transmit painful impressions, and it might be supposed that the analogy would hold in the case of the senses of touch and temperature. It is found in some cases of disease that the prick of a pin may be felt as a touch one or two seconds before it becomes painful. But this is open to the explanation that the delay in the latter case may take place in the spinal cord owing to a different path of conduction rather than to a difference in the time that it takes to stimulate the end-organ. Painful sensations may result from excessive stimulation of a sensory nerve at any part of its course, which would seem to point in favour of the non-existence of special end-organs. With regard to the paths by which these various impulses reach the brain, we know (if we except the fifth cranial and the vagus nerves) that they reach the spinal cord by the posterior roots of the spinal nerves, and that those impulses which produce tactile, thermal, and painful sensations for the most part (though this has recently been questioned) travel up the side of the cord opposite to that at which they entered, but their exact course is not certainly determined. The path for the muscular sense impulses is by many regarded as lying in the posterior columns of the same side (see SPINAL CORD).

Within the medulla oblongata the obscurity as to the upward sensory conducting tracts is even greater than in the cord, not only in the case of the senses above mentioned, but also of the sense of hearing and taste. It is probable that the paths are not continuous, but are frequently interrupted by nerve cells, through the agency of which the nervous impulses undergo successive elaborations before reaching the cerebral cortex. The evidence for the existence of special upward conducting strands in the spinal cord, and the connections of these, will be fully considered under the article SPINAL CORD.

See Landois and Stirling's *Physiology* (for details of investigations in various senses); Quain's *Anatomy* (for end-organs and nervous apparatus); Foster's *Physiology* (for general consideration of the problems involved). See also TASTE, NOSE, EYE, VISION, PERCEPTION, NERVOUS SYSTEM, PSYCHOLOGY, Vol. VIII. p. 474.

Sensitive Plant, a name commonly given to certain species of Mimosa (see MIMOSEÆ), on account of the peculiar phenomena of Irritability (q.v.) which their leaves exhibit in their collapse when touched or shaken. Numerous species of Mimosa possess this property, and, indeed, most of the species in a greater or less degree; but those in which it is most conspicuous are humble herbaceous or half-shrubby plants. They have leaves beautifully divided, again and again pinnate, with a great number of small leaflets, of which the pairs close upwards when touched. On repeated or rougher touching the leaflets of the neighbouring *pinnæ* also close together, and all the pinnæ sink down, and at last the leaf-stalk itself sinks down, and the whole leaf hangs as if withered. If the stem is shaken all the leaves exhibit the same phenomena. After a short time the leaf-stalk rises, and the leaflets expand again. On account of this curious and interesting property some of the sensitive plants are frequently cultivated in our hothouses. They are generally treated as annuals, although capable of longer life. *M. sensitiva*, one of the best-known species on the continent of Europe, is a native of Brazil, with prickly stems and leaf-stalks, and small heads of rose-coloured flowers. *M. pudica* is the species most commonly cultivated in British hothouses; it is a branching annual growing from 1 to 2 feet high. *M. casta*, *M. pudibunda*, *M. palpitans*, and

M. viva are also among the most sensitive species. See the section on the movement of plants at PLANTS; also Dr G. Haberlandt, *Das reizleitende Gewebesystem der Sinnpflanze* (Leip. 1890).

Sensorium, the supposed centre of sensation or seat of the soul, once believed to be some spot in the brain. See BRAIN, PINEAL GLAND, SENSATION.

Sentinel, Sentry (from the Lat. *sentire*, 'to feel or perceive,' through the Ital. *sentinella*), a soldier or sailor marine at a point with the duty of watching for the approach of an enemy, or guarding the gun-park, camp, magazine, or other locality. When an army is in the field its front and flanks are protected by 'outposts.' These consist of a chain of pickets (some fifty men each), covered in front by the sentries they throw out, and assisted in rear by other bodies called 'supports.' Each picket would furnish two to four double sentry posts, so that no portion of ground along the front is unwatched. These double sentry posts must be visible to one another and to other sentries (single) who, posted over the piled arms of each picket, report their signals. Sometimes groups of three to six men, one watching, the rest lying down, are used instead of the double sentries. If attacked, sentries fall back on the pickets, and with them retire upon the supports. Each is entrusted with the 'parole' or countersign, and no person, however exalted in position, may approach or pass him without giving that as a signal. As the safety of the army depends upon the vigilance of the sentries, the punishment for sleeping when on sentry-duty on active service is death.

Sentis. See SANTIS.

Senussi (*Senússiya*), a Moslem confraternity of austere and fanatical doctrines, which has done much to unite the Mohammedan population of North Africa in hostility and resistance to foreign and infidel influences. Mohammed es-Senussi ('of the Senus mountains'), from Mostaganem in Algeria, became famous about 1830 in Fez for his sanctity. After performing the Haj to Mecca he founded a convent at Alexandria, but was excommunicated by the Sheikh ul-Islam and settled in the Libyan Desert, first near Bengazi in Barca, and then at Jerabub or Jaghbub near the oasis of Siwa. Here he established a prosperous college, and here in 1860 he died, being succeeded by his son, who claimed to be the promised Mahdi (q.v.), though his manifestation was to be postponed till 1892. The confraternity has ramifications all over North Africa, especially in Tripoli, Fezzan, and Gadames. The French have come into contact with them; their agents have repeatedly stopped European travellers; and after the death in 1885 of the Egyptian Mahdi, from whom they had carefully held aloof, they acquired additional influence in the Soudan. See Wingate, *Mahdiism and the Egyptian Sudan* (1891).

Seoní, the capital of a district in the Central Provinces of India, half-way between Nagpur and Jabalpur on the great Deccan road. Pop. 10,203.—There is another smaller Seoní (pop. 7100) 35 miles SW. of Hoshangabad.

Seoul, or SOUL, the capital of Corea, stands on the river Han, 75 miles from its entrance into the Yellow Sea and 57 miles from its port Chemulpo (q.v.). It lies in a natural basin, amongst granite hill-ranges, and is surrounded with walls. The streets are very narrow and very dirty, and the houses beggarly in the extreme. The city includes several wide, desolate squares. The royal palace and its adjuncts cover 600 acres of ground. Silk, paper, tobacco, mats, fans, and similar commodities are the principal products of native industry. Pop. 150,000; including extensive suburbs, 300,000.

Sepal. See CALYX, FLOWER.

Separate Estate. See HUSBAND AND WIFE.

Separation of married persons is either judicial or voluntary. If the parties enter into a deed or other arrangement to live separate, this is called a voluntary separation, and in general the legal rights of the parties are not altered, except that if the wife is provided with maintenance she has no longer an implied authority to bind the husband. And though voluntary separation is not encouraged by courts of law, yet effect will be given frequently to deliberate contracts of this kind entered into between the parties. Formerly the intervention of a trustee was in all cases necessary, but now an arrangement made directly between husband and wife is enforced by the English courts. In the United States the law of several states confers the right to contract, to maintain actions, &c. on a married woman who, for good cause, is living apart from her husband. See Stimson's *American Statute Law*; see also JUDICIAL SEPARATION.

Sephardim. See ASHKENAZ.

Sepharvaim. See BABYLONIA.

Sepia, *a brown pigment used as a water-colour.* It is prepared from the dark-brown colouring matter of the ink-bag of a few species of Cuttle-fish (q.v.), particularly *Sepia officinalis*, which, though chiefly fished for in the Adriatic and Mediterranean, is also found in British seas. The pigment from the dried ink-bags is dissolved in a solution of ammonia or soda and then precipitated by neutralising the alkali with hydrochloric acid, the precipitate being afterwards washed and dried. An ounce of the natural pigment will darken several thousand ounces of water. Sepia excels all other water-colours in the ease with which its tints can be evenly put on paper with a brush. It is much used by itself for sepia drawings, and also in combination with other colours for various subdued tints. It is, however, not suitable for oil-painting. Sepia is permanent when not exposed to sunshine. Strange to say, the pigment from the ink-bags of fossil cuttle-fish possesses the same colour and character as that from recent species. An 'Indian ink' is sometimes made from sepia. This substance appears to have been used both as an ink and a pigment by the ancients.

Sepoy, corrupted from the Persian *sipahi*, 'a soldier,' denotes a native Hindu soldier as distinguished from a European (white) soldier (*gora*).

Seps. See SKINK.

Septaria are ovate, flattened nodules of argillaceous limestone or ironstone, internally divided into numerous angular fragments by reticulating fissures radiating from the centre to the circumference, which are filled with some mineral substance, as carbonate of lime or sulphate of barytes, that has been infiltrated subsequent to their formation. The fissures have been produced by the cracking of the nodule when drying. They are largest and most numerous in the centre, and gradually decrease outwards, showing that the external crust had first become indurated, and so, preventing any alteration in the size of the whole mass, produced wider rents as the interior contracted. The radiating figure and the striking contrast between the dark body of argillaceous limestone or ironstone and the more or less transparent spary veins when the nodule is cut and polished have caused them to be manufactured into small tables and similar objects. Calcareous septarian nodules are extensively employed in the manufacture of cement. As they are composed of clay, lime, and iron, they form a cement which hardens under water, and which is known commercially as Roman cement, because of its properties being the same as a famous hydraulic cement made of ferruginous volcanic ash brought from Rome. Such septaria occur in layers in clay deposits, and are quarried for economical purposes in the clays of the London basin. Large numbers are also dredged up off Harwich, which have been washed out of the shore-cliffs by the waves. The septarian nodules of the Carboniferous strata consist generally of clay ironstone, and are sometimes employed in the manufacture of iron. The nodules generally contain a scale, shell, plant, fruit, coprolite, or some other organic substance, forming the nucleus that has apparently excited the metamorphic action which withdrew from the surrounding clay the calcareous and ferruginous materials scattered through it, and aggregated them around the fossil.

September (Lat. *septem*, 'seven') was the seventh month of the Roman calendar, but is the ninth according to our reckoning (see CALENDAR). The Anglo-Saxons called it *gerst-monath*, 'barley-month.'

Septembrists, the perpetrators of the atrocious September massacres in the prisons of Paris, which went on continuously for six days and five nights, September 2-7, 1792. Every violent movement in the history of Paris during the fever of Revolution was a counterpart to some menace or disaster on the frontier, and the immediate occasion of this crowning atrocity was the reaction of panic at the capture of Longwy and Verdun by the Prussians. It assured the political power of the Commune and controlled the elections to the Convention. Las Cases tells us that Napoleon found himself able to suggest apologies for the atrocity in the exigencies of the moment. M. Taine gives the number of victims as follows: 171 at the Abbaye, 169 at La Force, 223 at the Châtelet, 328 at the Conciergerie, 73 at the Tour-Saint Bernard, 120 at the Carmelites, 79 at Saint-Firmin, 170 at Bicêtre, 35 at the Salpêtrière; among them 250 priests and the Princess de Lamballe. See DANTON, MARAT, and ROBESPIERRE.

Septennial Act. See PARLIAMENT, p. 776.

Septicæmia. See GERM, PYÆMIA.

Septuagesima. See QUINQUAGESIMA.

Septuagint (Gr. οἱ ό; Lat. *Septuaginta*, LXX., Alexandrian Version), the most ancient translation of the Old Testament, important as the version used by Christ and the apostles, and as the chief surviving witness to the purity of the text of the Hebrew Scriptures. It derives its name from the story of its origin, first told in the *Letter of Aristeas*, which purports to have been written by a Greek of Alexandria at the time of the events to which it refers. Aristeas relates how King Ptolemy Philadelphus (284–247 B.C.), when engaged in making a collection of the laws of all nations for the great Alexandrian library, was advised by his librarian, Demetrius Phalereus, to have the Jewish Scriptures translated into Greek; how the king sent an embassy to Jerusalem to request the help of the wise men of Israel; how seventy-two learned Jews (six out of each tribe) came to Alexandria and were sent to labour in the seclusion of the Island of Pharos; and how, in seventy-two days, they dictated to Demetrius the librarian a translation of the whole Scriptures, which soon became the authorised Bible of the Greek-speaking Jews. This story is a mixture of truth and romance. It is certain the Alexandrian version was the work of Hellenistic Jews. It is highly probable that it was a product of the great literary activity of the age of Ptolemy II. It is probable that the translation was begun at the king's instigation. It is possible that the king's aim was not the satisfaction of a pressing want among his Jewish subjects, but simply the gratification of personal curiosity. But the picturesque details of the story—the embassy to Jerusalem, the choice of seventy-two translators, the seventy-two day's sojourn on Pharos, and so on—are purely mythical. Internal evidence shows that the translators—who were certainly numerous—were not Palestinian but Egyptian Jews. And it can be demonstrated that they were not a public body meeting and deliberating daily for a short period, but private individuals working independently in different ages. Where there are many different styles of work and many degrees of excellence, we make the inference that there were many independent workmen; and nothing is more striking than the want of uniformity in the LXX. Some of the workmen were evidently more competent than others, some more conscientious. Some aimed at exact translation, some at writing good Greek. Some liked to condense, some to expand. Infinite care seems to have been bestowed upon the Pentateuch. The translators of the Psalms and the Prophets were hardly equal to their difficult task. Some books, such as Ecclesiastes, Canticles, and Chronicles, are rendered into extremely Hebraic Greek. Others, such as Job and Proverbs, of which the Greek is excellent, must be regarded as paraphrases rather than translations.

Taking these things into account, one is prepared to find in the LXX. numerous small deviations from the received Hebrew text, due partly to the unskilfulness, partly to the arbitrariness of some of the translators. But there are divergencies of a more important kind. The books are differently arranged. In some books the order of the chapters is quite different. Additions and omissions are alike frequent. Occasionally, as in the books of Job, Esther, and Daniel, the Greek text contains whole chapters for which there is no equivalent in Hebrew. These variations offer an interesting problem for solution. How are they to be accounted for? They cannot be regarded as mere mistakes or caprices of the translators. They seem clearly to indicate that the Hebrew text which formed the basis of the LXX. was not the text that has come down to us—that the LXX. is the translation of an ancient text which has been lost; as such it is invaluable. It may be used as practically a second, independent text of the Old Testament. It cannot indeed be trusted implicitly. As a translation it has blemishes, and in the course of transmission many corruptions have crept into the text. But with all drawbacks it is of immense service in textual criticism. It not only establishes the general accuracy of the Massoretic text, but supplies the means of solving many of the difficulties of that text.

The LXX. has also close and important bearings upon the New Testament. The historical links of connection between them are as follows: Ptolemy's gift of the LXX. to his Jewish subjects was gladly accepted. It soon began to be used in the synagogues. Before long it found its way from Egypt into Palestine, and by the time of Christ it had almost entirely superseded the original Hebrew text. Thus it became the Bible of Christ and the apostles. Not only was it the source from which the authors of the New Testament drew almost all their quotations, but it created the very language in which they wrote. The Egyptian Jews who adopted the Greek language never adopted Greek ideas; they modified the language to suit their own ideas; they gave a new content to many important words. Thus there arose a dialect which was Greek in form but entirely Semitic in spirit. The LXX. stereotyped that dialect, and the evangelists and apostles spoke and wrote it. Thus the LXX. is the key to the language of the New Testament. This fact is only now beginning to be duly appreciated. The great mistake of New Testament students has been to assume that the language of the New Testament is essentially that of classical Greek. It is never safe to assume that a word in the New Testament has its classical meaning. It is nearly always safe to assume that it has the meaning which it bears in the LXX.

The principal MSS. of the LXX. are the Alexandrian codex in the British Museum, the Vatican codex in Rome, and the Sinaitic (defective) in St Petersburg. The chief editions are the Complutensian (1514–17), the Aldine (Venice, 1518), the Sixtine (Rome, 1587), Reineccius (Leip. 1730), Parsons and Holmes (Oxford, 1798–1827), Tischendorf (Leip. 1850), Swete (Cambridge, vols. i. and ii., 1887–91). Important contributions have been made to the study of the LXX. in recent years by Lagarde, Wellhausen, Hatch, and others. Much, however, remains to be done before a satisfactory critical edition can be produced.

The Old Testament Apocrypha (q.v.) consists of books and parts of books in the LXX., and not included in our Hebrew Bibles. For other versions of the Hebrew, see Bible (Vol. II. p. 122), Aquila, Hexapla, Origen, Polyglot. The first part of *a Concordance to the LXX.*, by Hatch and Redpath, appeared in 1891.

Sepulchral Mound. See Barrow, Burial, Cairn.

Sepulveda, Juan Gines, a Spanish historian, was born at Pozo-blanco, in the neighbourhood of Cordova, about 1490, studied first at Cordova and Alcala de Henares, and went to Bologna in 1515, where and at Rome he became acquainted with the most celebrated savants of Italy and Spain. In 1536 he returned to Spain as historiographer to Charles V. and preceptor to his son, afterwards Philip II. After living successively in Valladolid, Cordova, and Madrid, he was made a canon of Salamanca. In that town he died on 23d November 1574. He won a reputation as the champion of humanism against the prevailing scholasticism. His principal work is entitled *Historia Caroli V.*, published with a biography and Sepulveda's other works by the Madrid Academy in 4 vols. in 1780. His other works include a Life of Albornoz, a History of the Reign of Philip II., and a History of Spain in the New World.

Séquard. See Brown-Séquard.

Sequence. See Hymn, Vol. VI. p. 46.

Sequestration, the Scotch legal term for Bankruptcy (q.v.).—In English law sequestration is a prerogative form of process, by which commissioners are empowered to take possession of the property of a person who is in contempt. There is also a special form of sequestration issued against a clergyman, by which the bishop is commanded to sequester the profits of the debtor's benefice to answer the plaintiff's claim. On sequestration the bishop is required to appoint a curate and assign him a stipend.

Sequin (Ital. *zecchino*, from *zecca*, the name of the Venetian mint), a gold coin of Venice, equivalent to the gold Ducat (q.v.).

Sequoia, a small genus (two species) of evergreen coniferous trees belonging to California. *S. gigantea*, better known in Britain as *Wellingtonia*, in other countries as *Washingtonia* and *Gigantabies*, is the 'Mammoth Tree' of California. Sequoia is a Latinised form of the name of the famous Cherokee chief, Sequoyah (see Cherokees). The mammoth tree, which is surpassed in height only by the Eucalyptus (q.v.) of Australia, was discovered by Douglas in 1831, though its existence was recorded by Menzies in 1796; it was introduced into Britain in 1853 by Lobb. The tree, though found at elevations varying from 4000 to 7000 feet above sea-level, affects only sheltered valleys, in which it occurs in groves intermixed with other trees. The most remarkable of these groves is in Calaveras county; only less remarkable is that of Mariposa near the Yosemite Valley. The 'Mammoth Grove' of Calaveras consists of from 90 to 100 trees of gigantic proportions. One of the most notable is named 'Mother of the Forest.' It rises to the height of 327 feet, but is dead and barkless, though it girths 75 feet near the base. The bark, about 18 inches thick, was removed in sections by Mr G. L. Trask to the height of 116 feet (causing the death of the tree), and fitted up as it came from the tree in the Crystal Palace, Sydenham, to illustrate the proportions of the mammoth tree; this erection was destroyed by fire in 1866. Near by the 'Mother' lies prostrate the trunk of the 'Father of the Forest,' which girths at the ground 110 feet. In falling the trunk had broken over at the height of 300 feet. At that point the girth is 40 feet, and taking the average taper of the surrounding trees, this dead giant may reasonably be computed to have exceeded 400 feet at the time of its fall. Inside the fallen trunk there is a tunnel 35 feet long, and from 8 to 10 feet high. The 'Pioneer's Cabin,' a cavity in the trunk of another giant in this grove, is large enough to accommodate a numerous party at dinner. The 'Three Graces' (see fig. 1), growing within a few feet of each other, became famous for their symmetry and beauty; they attain almost equally to the height of 265 feet. The age of these larger specimens is variously estimated at from 2000 to 3000 years; such estimates, however, based as they are on the enumeration of the concentric rings of the trunk, are not to be implicitly relied upon, particularly in the case of evergreen trees. The timber of the mammoth tree is reddish in colour when matured, non-resinous, and inodorous, the fibre short, porous, and brittle; it is not regarded as durable. In Britain, when planted in rich alluvial soil in well-sheltered positions, it is found to rival the Larch or any of the more rapid growing timber-trees in the production of timber in a given time. The tree is hardy enough to resist the severest frost likely ever to be experienced in Britain, but will not endure wind, especially that from the north and east. There are several varieties in commerce, the result of cultivation—viz. *S. g. pendula* and *S. g. aurea*, which cannot be said to be in either case improvements on the faultless cone-like symmetry of growth which characterises the typical form. *S. sempervirens*, the other species, is the Redwood or Bastard-tree of the Californian

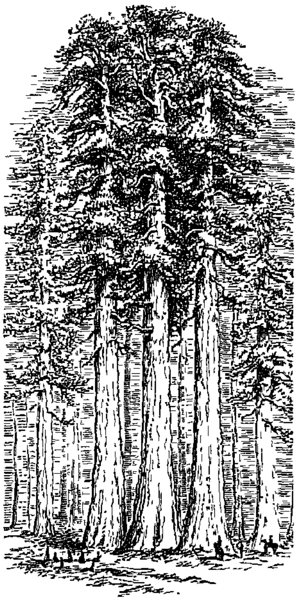

Fig. 1.—*Sequoia gigantea*—the 'Three Graces.'

settlers, a handsome tree also of gigantic proportions. Though apt to assume a rusty appearance in winter in Britain, the effect of wind, the tree is perfectly hardy, and grows with great rapidity when planted in good soil and in sheltered places. The timber is light, beautifully grained, and durable, but splits with remarkable facility; so that though very useful to the Californian settlers for fences, &c., it is not good for purposes of carpentry. Both species are prized as ornamental trees, and no collection of choice conifers can be regarded as complete without them. See CONIFERÆ.

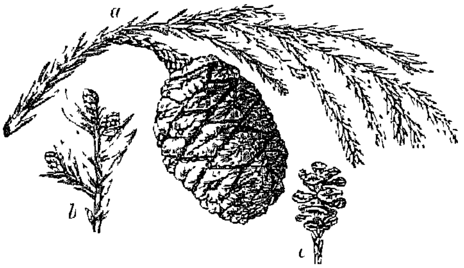

Fig. 2.

a, twig of *Sequoia gigantea*, with cone; *b*, *Sequoia sempervirens*, with male inflorescence; *c*, cone of latter.

Sequoyah. See CHEROKEES.

Seraglio, an Italian word meaning 'enclosure' (from *sera*, 'a bolt'), once used in English for any enclosure such as the Jews' Ghetto at Rome, but now restricted to mean a harem or suite of women's apartments, apparently from a confusion with the similar but totally distinct Persian (and Turkish) word *serai*, 'a king's court,' 'palace,' also 'a caravanserai.' The Seraglio (*eski serai*, 'old palace'), the ancient residence of the sultan at Constantinople, stands in a beautiful situation, where Stamboul juts farthest into the Bosporus, and encloses within its walls a variety of mosques, gardens, and large edifices, the chief of which is the Harem (q.v.). It is not now the residence of the sultans; see CONSTANTINOPLE.

Seraïevo. See BOSNA-SERAI.

Seraing, a town of Belgium, 4 miles by rail SW. of Liége, stands on the right bank of the Meuse, and is connected by a handsome suspension bridge with the village of Jemeppe. It is the seat of a colossal manufactory of steam-machinery, locomotives, &c., which was established by an Englishman, John Cockerill (q.v.), in 1817 in the old summer palace of the bishops of Liége. On his death in 1840 the concern passed into the hands of the John Cockerill Society. It now employs some 12,000 workpeople in hundreds of machine-shops, furnace-yards, forges, boiler-works, coal-mines, and other branches. In this establishment were made the first locomotive used on the Continent (1835), the machinery for boring the Mont Cenis tunnel, and the great lion on the field of Waterloo. Pop. (1827) 2000; (1881) 28,385; (1890) 33,912.

Serampur, a town of India, built in the European style, and extending a mile along the right bank of the Hooghly, 13 miles by rail N. of Calcutta. Paper and mats are manufactured. It was at one time a Danish settlement, but was transferred by purchase to the British in 1845. It is celebrated for the labours of the Baptist missionaries Carey, Marshman, and Ward. Pop. 25,559.

Serang. See CERAM.

Serao, MATILDE, an Italian novelist, was born at Patras in Greece, on 7th March 1856, the daughter of an Italian political refugee and a Greek lady. She was brought up partly in Greece, partly in Italy, and began her literary career in 1878 by writing tales and sketches for various journals. Her fame was established in 1881 and 1883 by two ambitious romances, which, whilst giving evidence of her study of French models of the realistic school, revealed also her own high talents of observation and description. Her best books are those dealing with various phases of Neapolitan life, as *Cuore Infermo* (1881), *Fantasia* (1883; Eng. trans. 1891), *Le Leggende Napoletane*, *Riccardo Joanna* (1886), and *All' Erta Sentinella* (1889, a collection of stories). Her *Piccole Anime* is a charming book about children, written for grown-up people who love the little ones. She has also written sympathetically of young girls and young women in the collection of stories entitled *Il Romanzo della Fanciulla*, and in *Telegrafi dello Stato* and other books. In 1887 she undertook the editorship of the influential and widely-read journal *Il Corriere di Napoli*.

Seraphim, celestial beings on either side of the throne of Jehovah, seen in prophetic vision by Isaiah, and by him alone (vi. 2-6). They have each six wings, two of which cover their faces in awe of the divine glory, and two cover their feet—an oriental sign of reverence—as the cherubim do their bodies (Ezek. i. 2), while the two remaining outspread wings support them. They hover above on both sides of the throne like two semicircular choirs, worshipping Him that sits on the throne in an uninterrupted antiphonal song. The tradition of the church, which took its rise from Dionysius the Areopagite, represents them as at the head of the nine choirs of angels, the first rank being formed by the seraphim, cherubim, and *throni*. The cherubim of Ezekiel are three-fourths in animal form, and the writer of the Apocalypse gives animal forms to three of the four ζῶα ('beasts;' R.V., 'living creatures'), which are six-winged like the seraphim of Isaiah (Rev. iv. 7, 8); the seraphim thus appear, apart from what was human-shaped in them, necessarily to be represented as winged dragons; for the serpent lifted up by Moses is called *Sārāph* (Num. xxi. 8), as is the flying dragon in xiv. 29. The name thus involves the idea of burning, and it is worth noting at least that Driver and Riehm see in the *cherub* of the original extra-Israelite representation the personified thunder-cloud, and in the *seraph* the personified serpent-like lightning.

Seraphine, a keyed musical instrument in which the sounds were produced by the action of wind on free vibratory reeds. It was the precursor of the Harmonium (q.v.).

Serap'is, or SARAPIS (also found as *Osarapis*), the Greek name of an Egyptian deity, introduced into Egypt in the time of Ptolemy I. or Soter, and really a combination of the Greek Hades and Egyptian Osiris. He was not an Egyptian, but the Greek deity, with some Egyptian characters superadded; and his temple was not admitted into the precincts of Egyptian cities, finding favour only in the Greek cities founded in Egypt. It is said that forty-two temples were erected under the Ptolemies and Romans to this god in Egypt. His resemblance to Osiris consisted in his chthonic or infernal character, as judge of the dead and ruler of Hades. The god had a magnificent temple (the *Serapeum*) at Alexandria, to which was attached the celebrated Library; another at Memphis, in the vicinity of the cemetery of the mummies of the Apis, which was excavated by Mariette in 1850; and another temple at Canopus. It appears that he represented or was identified with the Hesiri Api, or Osorapis, the 'Osirified' or 'dead Apis,' who was also invested with many of the attributes of Osiris. The worship of Serapis, introduced into Egypt by the Ptolemies, subsequently became greatly extended in Asia Minor; and his image, in alliance with that of Isis and other deities, appears on many of the coins of the imperial days of Rome. In 146 A.D. the worship of the god was introduced into the city of Rome by Antoninus Pius; but it was not long after abolished by the senate, on account of its licentious character. A celebrated temple of Serapis also existed at Puteoli (see POZZUOLI), near Naples, and the remains of it are still seen. In Egypt itself the worship of the deity subsisted till the fall of paganism, the image at Alexandria continuing to be worshipped till destroyed, 398 A.D., by Theophilus, archbishop of that city. Busts of Serapis are found in most museums, and his head or figure engraved on certain stones was supposed to possess particular mystic virtues.

Seraskier, the name given by the Turks to the commander-in-chief of the army or to the minister of war.

Serbs. See SERVIA.

Serenade (Ital. *serenata*), originally music performed in a calm night; hence an entertainment of music given by a lover to his mistress under her window—especially in Spain and Italy.—A piece of music characterised by the soft repose which is supposed to be in harmony with the stillness of night is sometimes called a serenade, more usually a Nocturne (see MUSIC, Vol. VII. p. 358).

Sereth, an affluent of the Danube, rises in the south of the Austrian crown-land of Galicia, runs southward through almost the whole length of Moldavia, and joins the Danube just above Galatz, after a course of nearly 300 miles.

Serf (Lat. *servus*, 'a slave'), the term usually given to the villeins of mediæval Europe, and to the unfree peasants of Russia. The *serf* was distinguished in a general way from the *slave* by being attached to the land and having certain definite rights, whereas the *slave* was the absolute chattel of his master. But serfdom falls to be treated as part of the subject of Slavery (q.v.).

Serge, a kind of twilled worsted cloth which has a wide range of quality, strength, and thickness. The surface of the fabric is not smooth like that of a milled woollen cloth. Serges are generally dyed a dark blue or black, and good qualities are very durable. Clothes made of serge have been much worn both by men and women of late years.

Sergeants, or SERJEANTS (through the Fr., from Lat. *serviens*, 'serving'), are non-commissioned officers of the army and marines in the grade next above corporal. They overlook the soldiers in barracks, and assist the officers in all ways in the field. They also command small bodies of men as guards, escorts, &c. The daily pay of a sergeant varies from 2s. 4d. in the infantry to 3s. 4d. in the horse artillery (see also NON-COMMISSIONED OFFICERS). There are three sergeants and one colour-sergeant in each company of infantry. Each troop of line cavalry has also three sergeants and one troop sergeant-major. In the Household Cavalry the corresponding non-commissioned officers are called corporals of horse (four per troop) and troop corporal-major. In the Royal Horse Artillery there are six sergeants per battery and one battery sergeant-major, whose pay is 4s. 4d. per day. A regimental sergeant-major is a warrant officer on the staff of a battalion of infantry, regiment of cavalry, or corresponding body of troops. The daily rate of pay varies from 6s. in the horse artillery to 5s. in the infantry. Unlike the sergeants, the sergeant-major does not command any particular portion of the corps, but generally superintends the whole of it, and in respect of discipline, &c. is the assistant of the adjutant. There is a separate article on COLOUR-SERGEANT. For the Quartermaster-sergeant, see QUARTERMASTER; for Sergeant-drummer and Sergeant-trumpeter, see BAND.—In ancient times the rank of sergeant was considerably more exalted. In the 12th century the sergeants were gentlemen of less than knightly rank, serving on horseback. Later the sergeants-at-arms were the royal body-guard of gentlemen armed *cap-a-pie*.

Sergeanty. See GRAND SERGEANTY.

Sergipe, a maritime state of Brazil, the smallest in the republic, but the second in density of population (31 per square mile), is bounded on the N. by the São Francisco, which separates it from Alagoas, and on the W. and S. by Bahia. Area, 7370 sq. m.; pop. (1888) 232,640. The shores are low and sandy, the interior mountainous. The east part is fertile, well wooded, and produces sugar and cotton; the western plateaus are devoted principally to the rearing of cattle. The capital is Aracajú, with a small port and 5000 inhabitants.

Sericite. See MICA.

Series, in Algebra, is the sum of a set of terms formed according to some definite law. For example, let n be any integer, and $\phi(n)$ a definite function of n. Then, by giving n the successive values 1, 2, 3, &c., and forming the corresponding functions $\phi(1)$, $\phi(2)$, &c., we are able to construct the series $S = \phi(1) + \phi(2) + \ldots + \phi(m)$, where m is the highest value of n that is to be involved. If $\phi(n)$ is simply a multiple of n, we get an Arithmetical Progression (q.v.), viz. $a + 2a + 3a + \ldots$ Again, if $\phi(n)$ is of the form a^n, we get a Geometrical Progression (q.v.), viz. $a + a^2 + a^3 + \ldots$ These simplest cases of series are considered under their special headings, and shall not be again referred to except by way of illustration.

It is evident that if a finite number of terms be taken, and if no term has an infinite value, the series itself will have a finite and determinate value. We may suppose, however, that no limit is to be assigned to the number of terms that are to be taken—in other words, that the highest value (m) of n is to be larger than any assignable quantity. We thus get a series with an infinite number of terms. But it does not follow that such an Infinite Series, as it is called, has necessarily an infinite value. Consider, for example, the Geometrical Series $1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \ldots$ to infinity. Draw a line ABC equal in length to two units. AB (= 1) will represent the first term of the series; the second term may be represented by BD, the half of BC; the third by DE, the half of DC; and so on indefinitely. It is evident that, however far we may go, we shall always fall short of C by an amount equal to the last bit added on. Thus

$$1 + \tfrac{1}{2} + \tfrac{1}{4} + \ldots + \tfrac{1}{2^n} = 2 - \tfrac{1}{2^n}.$$

But by taking n large enough we may make $1/2^n$ as small as we please. Hence the value of the Infinite Series is 2.

It will be seen that the terms in this series approach zero indefinitely, while the sum approaches a definite limit. Any series in which the latter condition is satisfied is called a Convergent Series. In all convergent series the former condition just stated must also be satisfied. But it does not follow that a series whose successive terms approach zero indefinitely is necessarily convergent. For example, the series $1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} +$

$\frac{1}{5}$ + . . . to infinity has not a finite value, is not convergent, although its infinite term is zero. Such a series is divergent, and cannot be summed to infinity. To prove this throw the series into groups of terms, the first group being the first term, the second the next *two*, the third the next *four*, the fourth the next *eight*, and so on. Thus the fifth group will consist of sixteen terms, beginning with $\frac{1}{16}$ and ending with $\frac{1}{31}$. Each of these fractions is greater than $\frac{1}{32}$ or $1/2^5$; so that their sum is greater than sixteen times this quantity or $2^4/2^5$ or $\frac{1}{2}$. Hence, if we go as far as m groups, the series will be greater than $1 + \frac{1}{2}m$. Thus by taking m large enough we can make the sum as large as we please. The series is divergent and cannot be summed. We may, however, by simply changing the algebraic sign of every alternate term, obtain a series which is convergent—viz. $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \ldots$ to infinity. That this series has a finite sum may be made evident graphically thus: Take AB equal to unity; this is the first term. Move back half-way to C; this gives the second term *minus* one-half. Move forward to D, where CD is one-third; then back to E, where DE is one-fourth; and so on indefinitely. It is clear that we shall ultimately oscillate through diminishing ranges about some point between C and B; so that the sum of this series is less than 1 but greater than $\frac{1}{2}$. The series, in fact, is the Napierian logarithm of 2, and has the value ·69315 . . . A series like that just given, which is convergent only when the signs of the successive terms differ according to some definite rule, is usually called *semi-convergent*. A series which converges when all its terms have the same sign is said to be *absolutely convergent*. Sir G. B. Stokes long ago distinguished them as *accidentally* and *essentially* convergent, a terminology which seems in many respects superior to that in common use.

It is important to have a test of convergency; and the most useful test is to take the ratio of two consecutive terms, and consider what value this ratio approaches as we take the terms higher and higher. This ratio is called the ratio of convergency; if it is ultimately less than unity the series is convergent; if greater than unity, divergent. This test, however, gives no information when the ratio is ultimately unity. As an example, consider the exponential series:

$$1 + x + \frac{x^2}{1.2} + \frac{x^3}{1.2.3} + \frac{x^4}{1.2.3.4} + \&c.$$

Here the ratio of the $(n + 1)$ to the nth term is $x/(n + 1)$, which is ultimately zero, since whatever value x may have n can be taken as large as we please, so that the ratio may be made smaller than any assignable quantity. As is well known, the value of this series is e^x, where e has the value 2·71828 . . . (see LOGARITHM). Convergent series are of indispensable service in the calculation of logarithms and trigonometrical functions and in many important physical applications. Not a few of their properties were consequently known to the earlier analysts; but it is to Cauchy (1827) that we owe the foundation and partial development of the modern theory of convergence. Dirichlet, Abel, Gauss, De Morgan, Bertrand, Kummer, Du Bois-Reymond, and others have ably supplemented Cauchy's work. A very complete introduction to the whole subject is given in Chrystal's *Algebra* (vol. ii.). There also will be found a discussion of certain parts of the subject which we can only name, such as oscillating series, double series, infinite products, reversion of series, and the like. See CIRCLE and TRIGONOMETRY for some particular cases of series.

Serinagar. See SRINAGAR.

Seringapatam (properly *Sri Ranga Patanam* = 'City of Vishnu'), the capital of Mysore state in Southern India from 1610 to 1799, is built on an island in the Kaveri, 10 miles NE. of the city of Mysore. The island is three miles long and one broad; at its western end stands the fort, surrounded by strong walls of stone, and enclosing the palace of Tippoo Saib and the principal mosque. Outside it are the garden in which was built the mausoleum of Tippoo and his father, Hyder Ali, and Tippoo's summer palace. The fort was besieged by Lord Cornwallis in 1791, and again in 1792. On the last occasion the terms dictated by the British to Tippoo were very severe. A British army appeared before the walls again in 1799, and on the 3d May of that year the fort was stormed and Tippoo slain in the vicinity of his own palace. Pop. 150,000 in Tippoo's day; 32,000 in 1800; (1881) 11,734, most of whom live at the suburb of Ganjam, the ancient city being now in a very ruinous condition.

Seringham (*Srirangam*), a town in the Madras Presidency, on an island in the Kaveri, 11 miles W. of Trichinopoly, with a pop. of 19,773. The place is noted for its great temple of Vishnu, a vast complex of halls and gopuras (colossal gateways) built on no very regular plan, but enclosing so large an area that most of the houses of the town are within the temple walls. Notable is one 'hall of a 1000 columns' (960 really), 450 feet long by 130 wide.

Serjeant-at-Arms, in the English Court of Chancery, is the officer who attends upon the Lord Chancellor with the mace, and who executes by himself or deputies various writs of process directed to him in the course of a Chancery suit, such as apprehending parties who are pronounced to be in contempt of the court. A similar officer attends on each House of Parliament, and arrests any person ordered by the House to be arrested.

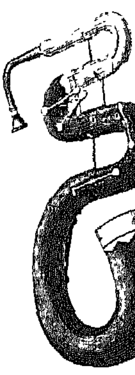
Serjeant-at-Law used to be the highest degree of barrister in the common law of England. The degree is of great antiquity, and formerly a barrister could only be appointed after being of sixteen years' standing. Formerly, also, they had exclusive audience in the Court of Common Pleas. The proper forensic dress of serjeants was a violet-coloured robe with a scarlet hood, and a black coif, represented in modern times by a patch of silk at the top of the wig. A serjeant was appointed by a writ or patent of the crown. The Chief-justice of the Common Pleas recommended the barrister to the Lord Chancellor, who advised the crown. The degree of serjeant was entirely honorary, and merely gave precedence over barristers; and when he was appointed he was rung out of the Inn of Court to which he belonged, and thereafter joined the brotherhood of Serjeants, who formed a separate community. By ancient custom the common-law judges were always admitted to the order of serjeants before sitting as judges, but this practice was abolished in 1874. The society of Serjeants' Inn was dissolved not long after, and the order is now extinct; a few surviving serjeants retain the title. See the article COIF; Pulling's *Order of the Coif* (1884); and Worbryde's *Eminent Serjeants-at-Law* (1869).

Sermons. See PREACHING.

Serous Fluids, various fluids occurring in the animal body, are arranged by Gorup-Besanez under three heads: (1) Those which are contained in the serous sacs of the body, as the cerebro-spinal fluid, the pericardial fluid, the peritoneal fluid, the pleural fluid, the fluid of the tunica vaginalis testis, and the synovial fluid; (2) the tears and the fluids existing in the eyeball, the amniotic fluid, and transudations into the tissue of organs; (3) morbid or excessive transudations, such as dropsical fluids, the fluids occurring in hydatids, and in blebs and vesicles on the skin, and transudations from the blood in the intestinal capillaries, as in cases of intestinal catarrh, cholear, or dysentery. All these fluids bear a close resemblance to one another, both in their physical and chemical characters. In so far as relates to their physical characters they are usually clear and transparent, colourless or slightly yellow, of a slight saline, mawkish taste, and exhibiting an alkaline reaction with test-paper. They possess no special formal or histological elements, but on a microscopic examination blood-corpuscles, cells of various kinds, molecular granules, and epithelium may occasionally be observed in them. The ordinary chemical constituents of these fluids are water, fibrin (occasionally), albumen, the fats, animal soaps, cholesterin, extractive matters, urea (occasionally), the same inorganic salts which are found in the serum of the blood, and the same gases as occur in the blood.

Serous Membranes. There are six of these membranes in the human body, two being median and single, while two are double and lateral. They are the pericardium and the peritoneum, with the two pleuræ and tunicæ vaginales testis. They are all closed sacs, with one exception; and each sac or continuous membrane consists of two portions—a parietal one, which lines the walls of the cavity, and a visceral or reflected one, which forms an almost complete coating or investment for the viscera contained in the cavity. The interior of the sac contains a small quantity of fluid, usually merely enough to moisten the contiguous surfaces and thereby enable them to glide easily upon each other. With regard to their structure, it is sufficient to state that they consist essentially of (1) endothelium; (2) basement membrane; (3) a stratum of areolar or cellular tissue, which constitutes the chief thickness of the membrane, and is the constituent on which its physical properties are mainly dependent. This layer is more liable to variation than the others, and one of the most common alterations is an augmentation of the yellow fibrous element, by which an increased elasticity is given to the membrane, which is thus better adapted for distention, and for a subsequent return to its original bulk. The situations in which this augmentation is found are, as Dr Brinton (*Cyclopædia of Anatomy and Physiology*, vol. iv. p. 524) has pointed out, in exact conformity with this view: in the peritoneum, which lines the anterior abdominal wall and covers the bladder, it attains its maximum; in the detached folds of the mesentery, in the costal pleuræ, and in the suspensory ligament of the liver it is still very prominent; while on the posterior wall of the belly, and in serous membranes covering the heart, liver, &c. it is almost absent. For some of the principal serous membranes, see the articles PERICARDIUM, PERITONEUM, PLEURISY, and RESPIRATION (Vol. VIII. p. 660).—Synovial membranes (q.v.) present many points of similarity to serous membranes.

Serpent, a bass musical wind-instrument entirely obsolete except in a few continental churches. It is said to have been invented by a French priest at Auxerre in 1590. It consists of a tapered tube 8 feet long, built of wood and covered with leather, and twisted about like a serpent, whence the name. It is sounded through a cupped mouthpiece like that of the bass Trombone (q.v.). It had originally six holes for three fingers of each hand, but in its later years had keys added. The form of its bore and the material of which it is made give it a tender and soft tone which is very effective in certain kinds of music, but its difficulties and the uncertainty of its intonation have led to its disuse.



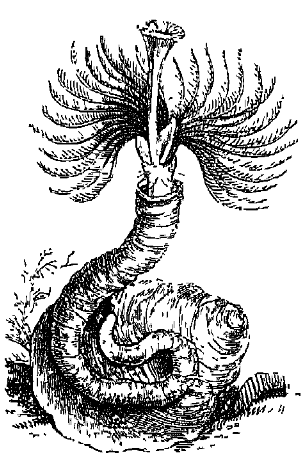
Serpent.

Serpentine, a mineral composed of silica and magnesia in almost equal proportions, with about 13–15 per cent. of water, and a little protoxide of iron. Serpentine occurs generally massive; never in crystals, save as pseudomorphs; colour some shade of green, also red and brownish yellow; has a smooth but sometimes greasy feel; is soft enough to be scratched with calcite. Precious Serpentine, or Noble Serpentine, is of a rich, dark-green colour, hard enough to receive a good polish, translucent, and sometimes contains imbedded garnets, which form red spots, and add much to its beauty. It is a rare mineral. It occurs at Baireuth in Germany, in Corsica, at Portsoy in Banffshire, in the Shetland Islands, &c. It is generally found along with foliated limestone associated with schistose rocks. The ancient Romans used it for pillars and for many ornamental purposes; and vases, boxes, &c. are still made of it, and much prized. The ancients ascribed to it imaginary medicinal virtues. *Marmolite* is a scaly, foliated serpentine; *Chrysotile* is a delicately fibrous variety, with a silky lustre, often met with as veins in ordinary serpentine. *Common Serpentine* is a rock rather than a mineral. It often occurs in winding irregular veins; hence the name serpentine. It is generally green or red, the colour being sometimes uniform, at other times mottled, spotted, streaked, veined, or clouded. It occurs not only in veins, but forming irregular sheets and masses, and is usually associated with crystalline schists and granitoid eruptive rocks. The mineral serpentine is always a product of the chemical alteration of other minerals; and there is reason to believe that most of the masses of serpentine are highly altered igneous rocks which were rich in olivine or peridote. Many peridotites are proved to have been altered into serpentine. Concerning the origin of some of the serpentines associated with the crystalline schists there is still much uncertainty.

Serpents (Lat. *serpere*, 'to creep'), the more formal and old-fashioned term for all members of the genus Ophidia, more popularly known as Snakes (q.v.), under which heading the general characters and classification of the Ophidians are treated, as also snake-charming.

SERPENT-WORSHIP is one of the most ancient and wide-spread forms of primitive religion, and still exists amongst many savage peoples. The characteristic change of skin is easily associated with notions of resurrection and immortality; but it does not appear that the familiar notion of the serpent as a personification of evil is anything like universally spread, although we do find it early in the Apophis-serpent of the Egyptian Hades, represented on mummy-cases, as well as in the wicked Aji Dahaka of the Zoroastrians, which bears so close a relation to the subtle Serpent of Eden. The worship of Moses' brazen serpent in the days of Hezekiah (2 Kings, xviii. 4) shows that the idea was familiar to the Semitic mind. Serpent-worship appears prominently in early Indian Buddhism; we see traces of it in the great serpent which defended the citadel of Athens, fed every month with honey-cakes; in the Roman *genius loci*, which was usually supposed to assume this form; and in the kindly offices between men and snakes so common in European folk-tales. Among the Zulus certain harmless green or brown snakes which come fearlessly into the houses are thought to be *amatongo* or ancestors, and may often be identified by some scar or mark such as the man bore in life. Serpents are by many peoples regarded as common incarnations of deities, whether ancestral or other, such as the rattlesnake worshipped in the Natchez temple of the Sun; the serpent-symbol of the healing deity Æsculapius, in whose temple huge tame snakes were kept; the Phœnician serpent with its tail in its mouth, perhaps originally a mere mythic world-snake like the Scandinavian Midgard-worm, but in later ages adopted as an emblem of eternity. Nothing in the history of serpent-worship is more remarkable than its Christian revival, or rather survival, among the mystic vagaries of Gnosticism—the Ophites trained their tame snakes to coil themselves round the eucharistic bread. Snake-worship again comes into close touch with the doctrine of Totemism, and we see how the Sanskrit *nága* ('serpent') has given the name to a race of snake-worshippers who claim descent from ancestral snakes. On no people has the mystery of the serpent (Prov. xxx. 19) weighed more than upon the Red Indians. It has given its name to rivers, like the Kennebec (Algonkin) and the Antietam (Iroquois); among the Dakotas, Shawnees, and Sacs the words for *spirit* and *snake* are similar; the Algonquins think the lightning an immense serpent, and the Caribs speak of the god of the thunderstorm as a mighty serpent. The Ojibways dread to kill a rattlesnake, and if they find one in their path they beseech it to go away and spare them and their families; the same worship was found among the Cherokees and many other tribes, as well as in the strange snake-dances practised among the Zuñis. In Mexico many sculptured images of serpents are found, almost vying in size and splendour with those found in India. The Vaudoux of Hayti (q.v.) is a special case of serpent-worship.

See Fergusson's *Tree and Serpent Worship* (1868); Gubernatis, *Zoological Mythology* (1874) for its facts; E. B. Tylor's *Primitive Culture* (1871); also ANIMAL-WORSHIP, BEAST-FABLES, OPHITES, TOTEMISM, &c.



Serpula contortuplicata (with expanded gills), on the back of an Oyster-shell.

Serpukoff, an ancient Russian town, 57 miles by rail S. of Moscow, on the Nara, 3 miles from its confluence with the Oka. It contains a cathedral (1380), and is a place of considerable commercial and industrial importance, manufacturing chiefly cottons, woollens, leather, paper, furniture, and earthenware. Pop. (1885) 20,983. It was formerly a fortress protecting Moscow on the south.

Serpula, a genus of sedentary Chætopod worms, living in twisted calcareous tubes fastened to shells and rocks in the sea, or even to other animals, such as crabs. From the mouth of the tube the head of the worm is stretched out into the water, and bears numerous exquisitely coloured gills and a stopper or operculum which closes the mouth of the shell when the head is retracted, and seems also to help in respiration. The colour of the gills is in great part due to the blood which is seen through the thin skin. The food consists of minute organic, and especially vegetable, particles, which are wafted into the mouth by the cilia on the gills. The process by which the worm makes its tube of lime is not clearly understood; it is interesting to observe that in situations where the light comes in one definite direction the calcareous tubes point that way. Several species of Serpula are common on British coasts, and large forms of this genus and of nearly related genera are common in warmer seas.

Serrano y Dominguez, FRANCISCO, DUKE DE LA TORRE, a Spanish statesman, was born at Anjonilla in Andalusia on 18th September 1810, and pushed himself to the front in the war against the Carlists. Having gained an intimate place in the favour of the dissolute Queen Isabella, he made the most of his influence and played an active part in the dismal political changes of that sovereign's reign, sometimes being in arms against the ministers of the day and sometimes himself holding the highest administrative posts of the kingdom. He was by profession a liberal, and for some years (1854-66) lent faithful support to O'Donnell. On the overthrow of O'Donnell's government by Narvaez Serrano was banished, but returning two years later (in 1868) he defeated the queen's troops, and, having driven her away into France, became the chief ruler (as regent) of Spain until the accession of Amadeus of Savoy (1870). He waged successful war against the Carlists both in 1872 and in 1874. During the greater part of this latter year he was again at the head of the government, until he resigned the power into the hands of Alfonso XII. He died at Madrid on 26th November 1885.

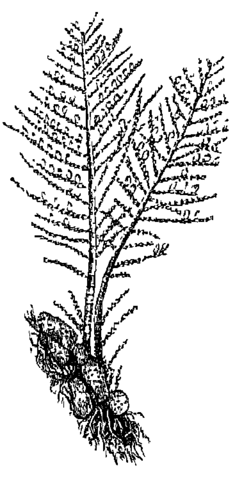
Serres, OLIVIA. See OLIVE (PRINCESS).

Sertorius, QUINTUS, one of the ablest Roman commanders in the later ages of the Republic, was a native of Nursia, in the country of the Sabines. He began his military career in Gaul, and fought (105 B.C.) in the disastrous battle on the Rhone in which the Roman proconsul, Q. Servilius Cæpio, was defeated by the Cimbri and Teutones, and took part in the splendid victory at Aquæ Sextiæ or Aix (102 B.C.), where Marius annihilated the same barbarians. On the breaking out of the sanguinary struggle between the party of the nobles under Sulla and the popular party headed by Marius (88 B.C.), he espoused the cause of the latter, though he could not respect Marius himself. For morally Sertorius was much superior to the military adventurers of his time; and the impression we have of him from Plutarch's picturesque biography is that of a valiant, resolute, honest, and stubborn Roman, such as was commoner in the 3d than in the 7th century of the Republic. None of the Marian generals held out so long or so successfully as he against the victorious oligarchy. He fought in conjunction with Cinna the battle at the Colline Gate, which placed Rome at the mercy of the Marians. But he took no active part in the bloody massacres that followed; on the contrary, he slew 4000 of Marius' cut-throat slaves who had committed the worst excesses. On the return of Sulla from the east (83 B.C.) Sertorius, finding it impossible to act in concert with the other military leaders of his party, went to Spain, where he continued the struggle in an independent fashion. At first he was unable to maintain his ground, and was obliged to put to sea. In the Mediterranean and in Morocco he led an adventurous life, sometimes fighting against the partisans of Sulla, sometimes mixing in the quarrels of native chiefs. But his fame grew, and at length he was invited back to Spain by the Lusitani; and from them and Roman refugees he formed troops who successfully defied the power of Rome for eight years or more. Sulla sent army after army against him commanded by such men as L. Domitius *Ahenobarbus*, Q. *Metellus Pius*, and young *Pompey*; but none of them was a match for him and his methods of guerilla warfare. The contest was at last terminated by the assassination of Sertorius in 72 B.C. The assassins were all Romans, men proscribed by Sulla, who were fighting under Sertorius. The chief of them was Perperna, who was jealous of his chief, and cherished ambitions of his own. Sertorius seems to have aimed at establishing a strong, stable government in Spain: he created a senate of 300 members from amongst the Romans of his party, and founded a school at Osca (Huesca) for the education of the sons of the Spanish chiefs. But jealousies broke out between the Spaniards and the Romans, and the sternness of Sertorius changed to cruelty and tyranny. But when at the height of his power he was regarded with almost superstitious veneration by the Lusitanians, and the feeling was enhanced by the fact that the great commander was constantly followed about by a tame fawn.

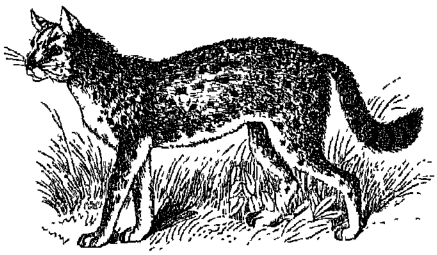


A Sertularian Colony (natural size).

Sertularia, a common genus of Hydroids, in which the branched horny investment of the plant-like colony forms a sessile cup around each polyp. The polyps are arranged in a double row, and the colony is attached to stones, shells, seaweeds, and the like. Among the hydrothecæ or cups surrounding the polyps or nutritive zooid larger pear-shaped capsules or gonothecæ occur, within which the reproductive elements are formed from special generative zooids. Unlike many Campanularians and Tubularians, the Sertularian hydroids never liberate medusoid reproductive individuals or zooids. See HYDROZOA, and Hinck's *British Hydroid Zoophytes* (2 vols. Lond. 1868).

Serum. See BLOOD.

Serval (*Felis Serval*), one of the smaller Felidæ,



Serval (*Felis Serval*).

a native of South Africa, the *Boschkatte*, or Bush-cat, of the Cape Colony. It is about two feet in length, exclusive of the tail. The serval is a beautiful animal, yellowish with black spots, the lower parts white with black spots. The fur of the serval is in great request, and is known to furriers as that of the *Tiger Cat*.

Servant. See MASTER AND SERVANT.

Servetus, MICHAEL, or MIGUEL SERVETO, a theologian and physician, was born at Tudela in Navarre in 1511, though he stated that he was born at Villanova near Lerida, and from about 1535 always styled himself Michael Villanovanus. His father sent him to study law at Saragossa and at Toulouse. His interest in theological discussions was awakened whilst he was yet a student, and having gone to Italy (1530) in the company of Quintaña, confessor to Charles V., he passed on from there into Germany, and came into contact with Luther, Œcolampadius, Bucer, and others of the Reformers. But his own views, especially in respect of the Trinity—he denied that there are three Persons in the Trinity and refused to acknowledge the eternity of the Son, and in other respects professed tenets similar to those of Socinus (q.v.)—were in discord both with those of the Reformers and the authoritative teaching of the Roman Catholic Church. The essay in which he propounded his speculations—*De Trinitatis Erroribus* (1531)—provoked considerable discussion. In 1536 he began to study medicine at Paris, and after a few years of wandering settled down to practise at Vienna (1541). Four or five years later he began to correspond with Calvin, and in spite of Calvin's openly avowed enmity wished to visit him at Geneva. At length, having secretly reprinted (1553) his collection of theological tracts, he was betrayed, and denounced, it is alleged at the instance of Calvin, to the inquisitor at Lyons. He was arrested, but managed to escape from prison; yet rashly venturing into Geneva he was again arrested, and after a trial of more than two months was burned alive (27th October 1553), the day after sentence was pronounced, at Champnel near Geneva. As a scientific inquirer he is best known by a popular book on syrups and by his demonstration of the pulmonary circulation of the blood.

See CALVIN; Tollin, *Charakterbild Michel Servet's* (1876), *Das Lehrsystem M. Servet's* (3 vols. 1876–78), and other books; Trechsel, *Die Protestantischen Antitrinitarier vor F. Socin* (1839); Pünjer, *De M. Serveti Doctrina* (1876); and Willis, *Servetus and Calvin* (1877), which, however, must be used with very great caution.

Servia, a kingdom of the Balkan Peninsula, bounded N. by the Danube, separating it from Hungary, W. by the Drina, separating it from Bosnia, S. by Turkey, and E. by Bulgaria and Roumania, the Danube flowing between Servia and the last named. It is a compact territory, with an area of 18,754 sq. m., measuring 140 miles from east to west by 110 from north to south. The surface is on the whole mountainous. There are, however, few well-defined mountain-chains, except along the frontiers, where also the highest peaks occur—e.g. the Kapaonik Mountains (6382 feet) in the south-west; but there are a great number of isolated mountain peaks and mountain groups, clothed in many parts with fine forests (12 per cent. of the total area) of oak, beech, walnut, chestnut, and other trees, and parted by fertile valleys, which afford excellent pasturage to numerous herds of cattle and sheep. The districts next Bulgaria and Bosnia are more wild and difficult than the central parts, through which passes the principal highway of the country, the valley of the Morava, stretching south-south-east from the Danube. Servia is essentially an agricultural country. Of the total area 58½ per cent. is set apart for cultivation, the principal crops being wheat, maize, and other cereals, and grapes for wine (annual production 2½ million gallons). Nearly 12 per cent. of the total is, however, uncultivated or lying waste. The extensive mountain pastures have been already mentioned. Fruit trees exist in very great abundance, especially plums (annual crop 25,000 tons), which are dried and exported to a value between £250,000 and £500,000 a year, and from which also the brandy of the Servians (*slivovitza*) is extensively made. Large herds of swine are fed on the acorns of the oak forests, and then driven into Hungary (mostly to Pesth) to be sold. Great numbers of cattle and sheep are kept, the former being exported to the value of nearly £250,000 annually. The remaining exports of consequence embrace wheat and other cereals (£150,000 to £430,000 annually), hides, wine, wool, timber, cordage, and sheep. The total exports for the six years ending 1890 averaged £1,589,000 annually. The imports consist principally of cottons, woollens, salt, timber, iron, steel, and other metals, hides, sugar, coffee, glass, paper, tobacco, machinery, &c., and range from £2,067,800 (1886) to £1,325,100 (1889). In addition to this there is a rapidly growing transit trade (£29,000 in 1887 and £556,000 in 1890). By far the greater portion of the foreign trade of Servia is in the hands of Austria-Hungary, and is concentrated at Belgrade, the capital of the country. But a little is done by Nisch, the chief town of southern Servia, by rail (since 1889) through Salonica (q.v.). The manufacturing industry is still in its infancy, though the government are trying to encourage it by the system of monopolies. There are, however, now in operation flour-mills, breweries, brick-works, cooperages, sawmills, and factories for making cloth, paper, tobacco, and gunpowder. Clothing and carpets are made by the women in their own homes. The country is naturally rich in minerals, though they are not extracted to anything like the extent they might be; nevertheless coal, lignite, quicksilver, lead, silver, antimony, copper, and oil shales are mined. Along the valley of the Morava passes part of the chief railway line connecting Vienna with Constantinople. This, together with three or four short branch-lines, gives to Servia a total of 334 miles of railway.

The Servians are a well-built, stalwart race, proud and martial by temperament, with a warm love of home and country, of dance and song, hospitable, brave, and energetic, but at the same time quick-tempered and prone to violence. They are a primitive people, cling to old customs and beliefs, and are thoroughly democratic in their institutions. The most striking feature of their social life is the family community or *Zadruga*. The farms are all small in size, and the agriculture is backward and primitive. There are no paupers, no asylums, no 'homes' in Servia. Pop. (1884) 1,901,736; (1890) 2,162,759, including some 150,000 Roumanians, 34,000 Gypsies, and 25,000 of other nationalities. Besides these there are some 250,000 Servians (Serbs, Sorbs) in Montenegro, 1,300,000 in Herzegovina, and 2,350,000 in Austria-Hungary. The people of Servia belong to the Greek Catholic Church. The highest authority of the Servian church is the national synod, consisting of the Archbishop of Belgrade (metropolitan of Servia) and the bishops of Nisch and Zica. Education does not reach a very high standard, and is not generally diffused, although attendance at the primary schools is free and compulsory. Besides a university (at Belgrade) with less than 300 students, there are a military academy, a theological seminary, an agricultural, a commercial, and some technical schools. The elementary schools number nearly 700, and are attended (1888) by about 52,000 children.

Servia is a constitutional and hereditary monarchy. The king or the regency acts as the sole executive, through eight ministers (for Foreign Affairs, War, Finance, Justice, Interior, Political Economy, Public Works, Religion and Education), who are responsible to the nation. The legislative power is vested in the king and the National Assembly. This last, called the *Skupshtina*, consists of deputies elected by the people every third year, one for every 4500 voters in each province. Besides this body there is a senate of sixteen members, eight chosen by the king and eight by the National Assembly; this body acts as a permanent state council. On extraordinary occasions four members are returned by every constituency instead of one. The national income in 1891 was £2,261,083, the expenditure £2,381,036; and in the same year the public debt amounted to £13,220,429. The army, armed from 1892 with the Mannlicher rifle, embraces all men capable of bearing arms between the ages of twenty and fifty, divided into three classes, the standing army, with a peace total of 14,000 and a war total of 70,000; the second and third class each numbers 55,000. The French (metrical) system of weights and measures is in use, and the coinage system of the Latin union, though the 'franc' is called *dinar*, and is divided into 100 *paras*.

See Gopcević, *Serbien und die Serben* (1888); Laveleye, *The Balkan Peninsula* (Eng. trans. Lond. 1887); E. de Borchgrave, *Le Royaume de Serbie* (Brussels, 1883); Kanitz, *Serbien* (Leip. 1868); Denton, *Servia and the Servians* (Lond. 1862); and the consular reports on the trade of Servia.

HISTORY.—The Servians emigrated from the slopes of the Carpathians to the regions now called Servia, Bosnia, and Herzegovina in the year 638, and not long afterwards accepted Christianity in the form adopted by the Eastern or Byzantine Church. The rulers of the people during the following four hundred years were powerful feudal lords, of whom now one, now the other, exercised the chief authority. Sometimes they were in subjection, in whole or in part, to the Byzantine emperors; but all through they steadily strove for the preservation of their independence, and in the long run successfully withstood the power of Byzantium, as well as resisted the unceasing attacks of the Bulgarians. Like most Eastern Christians, the people cherished an unconquerable aversion to the Latin Church and its head, the pope; and from the last years of the 12th century the Servians elected their own archbishop. A chief, Stephen Nemanya by name, founded the Rascian dynasty in 1159, and under his successors Servia pushed her way into the front rank amongst the Balkan states. The greatest ruler of this dynasty was Stephen Dushan (1336-56), who after subjugating Bulgaria, Macedonia, Albania, and the greater part of the peninsula, conceived the ambitious design of welding Servia, Bulgaria, and Byzantium into an empire strong enough to resist the assaults of the Osmanli Turks. But he died before he could carry out his plans. Under his feeble son and successor the great nobles divided the power amongst them, and consequently weakened the country. This favoured the aggressive advance of the Turks, who routed the chief Vukashin on the Maritza in 1371, and Prince Lazar at Kossovo, on the celebrated 'Field of the Blackbirds,' in 1389. By this last fight, which figures very prominently in the national ballads, the independence of Servia was virtually lost: she was made tributary to the sultan, and gradually became a pashalik of the Ottoman empire, though hopes of freedom were revived for a time by the great successes of the Hungarian captain and king Hunyady and the Albanian chief Scanderbeg in the middle of the 15th century.

During the next three hundred years the Turkish rulers, supported by the ruthless janizaries, ground down the unhappy people, and subjected them to almost every kind of injustice and barbarity: many of the chief families were exterminated, 200,000 persons were carried off as slaves, and in 1691 several thousands left their country for good and settled in Hungary. The people who remained behind were little better than serfs, and every seven years their boys were taken from them to be brought up in the Moslem faith and forced into the corps of the janizaries. The victories of Prince Eugene brought about the peace of Posharevatz (1718), by which Servia was ceded to Austria; but Austria had to restore it to the sultan twenty-one years later. At length the exasperated people, goaded to desperation, rose in 1804 under the leadership of Kara George, a stalwart and determined, though morose, swine-owner, a rich man and a man of influence, who by 1807 effectually drove the tyrannical janizaries out of the country, and stormed and took possession of Belgrade and the other fortresses. The struggle before its conclusion had taken on the character of a racial and religious war, Christian Servian against Mohammedan Turk. In 1809 and 1810 the Turks made determined efforts to recover their hold upon the country, and did overrun the districts east of the Morava; but with the assistance of the Russians they were at length beaten off again. By the treaty of Bucharest, which Russia made with Turkey, it was decreed that the sultan's troops should regarrison the fortresses, but that the Servians should govern themselves in respect of all internal affairs. But the Turks refused to observe these terms, and in 1813 assailed Servia on both sides with such vigour that Kara George fled to Austria and the enemy recovered the country. Turkish oppression again provoked an uprising of the people in 1815; they chose as their leader Milosh Obrenovich, a herdsman, who in a single campaign expelled the enemy, except the garrisons in the fortresses. This man was henceforth the leading spirit in the struggle of the Servians for independence. In 1817 he caused his rival Kara George, who had returned, to be assassinated, and was himself proclaimed chief ruler of Servia. In 1829 the Ottoman government at last formally agreed to the provisions of the treaty of Bucharest, and in the following year recognised Milosh as hereditary prince of Servia. But his rule was arbitrary and despotic, and in 1839 he was compelled to abdicate in favour of his son Milan (died same year). Before he abdicated the Turkish minister of Foreign Affairs and the Russian ambassador at Constantinople had drawn up a constitution, curtailing the power of the prince and giving much authority to a senate of the nobles. Milan's brother and successor, Michael (1839–42), was driven out of the country by a rival faction, who elected Alexander, son of Kara George, as their prince. Alexander leaned to Turkey and to Austria rather than to Russia, whose czar regarded himself as the rightful 'Protector of Servia,' and by this policy and his incapacity he lost the sympathy of his people and provoked many enemies about him. In 1859 he was compelled to abdicate, his successor being the aged exile, Milosh Obrenovich.

On his death, less than two years later, the chief power passed to his son Michael, who had been expelled in 1842. Under his rule a new era began for harassed Servia; the animosities of faction were smoothed away, the supremacy of the law was successfully vindicated and maintained, the national spirit was encouraged and foreign interference minimised, the national militia was organised, armed, and trained, and the country began to move forward along the path of progress and prosperity. In 1867 Michael procured the departure of the last Turkish garrisons from Servian soil, namely those of Belgrade, Shabatz, and Smederevo; all the others had been withdrawn in 1862. On 10th June 1868 Prince Michael was assassinated in the park of Topshidere near Belgrade, by partisans of the rival Kara George faction. He was succeeded by Milan IV., a grandson of Yephrem, brother of the heroic Milosh. The most notable events during the reign of Milan (1868–89) were the framing of a new constitution, which placed all real power in the hands of the prince and a freely elected national assembly of the people; a war against Turkey (1876), in which the Servians were routed, and only escaped punishment through the intervention of Russia; participation in the Russo-Turkish war of 1877–78, whereby Servia gained her complete independence, and in addition the districts of Nisch, Pirot, and Lescovatz; the proclamation of the prince as king Milan I. on 6th March 1882; war with Bulgaria (1885), in which the Servians were defeated by Prince Alexander (of Battenberg), ruler of Bulgaria, at Slivnitza and at Pirot, and were again saved by foreign intervention, this time that of Austria-Hungary; the quarrel between King Milan and Queen Nathalie, a Russian, their divorce (1888), and King Milan's abdication (1889) in favour of his son Alexander (born 14th August 1876).

See Ranke, *History of Servia* (Eng. trans. Lond. 1853), and *Serbien und die Türkei im 19ten Jahrhundert* (Leip. 1879); E. L. Mijatovics, *History of Modern Serbia* (Lond. 1872); René-Taillandier, *La Serbie au XIX^{e} Siècle* (1875); Kallay, *Geschichte der Serben* (Pesth, 1877); and compare E. de Laveleye, *Balkan Peninsula* (Eng. trans. Lond. 1887), and Denton, *Servia and the Servians* (Lond. 1862).

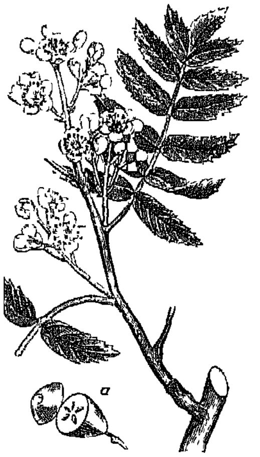
LANGUAGE AND LITERATURE.—The language of the Servians belongs to the southern division of the Slav tongues, and has for its nearest congeners Bulgarian, Slovenian, and Russian. Although somewhat influenced by Turkish, it is the softest tongue of all in the southern division, has a complete grammar, and readily lends itself to poetic composition. The dialect spoken by the Croats is precisely the same as that spoken by the Servians; but whilst the latter use the Cyrillic (Russian) alphabet, the former employ the Latin. The people of Montenegro and Bosnia speak Servian.

The earliest productions in Servian date from the 12th century, and consist of monkish chronicles and letters; in the 13th and 14th centuries various lives of the saints and kings, and annals, were written by Stephen Nemanya, St Sava, Archbishop Daniel, and others. But perhaps the most interesting production of this period is the collection of laws (*Zakonik*) made in 1349, when Stephen Dushan was king. Then came the battle of Kossovo and the long period of Turkish oppression, and during all that time there was no Servian literature except annals. But the language was not wholly uncultivated. From the end of the 15th down to the end of the 17th century a vigorous school of writers in Servian, or Croato-Servian, flourished at Ragusa (q.v.) on the Adriatic. It was not, however, a purely national literature, but was strongly influenced by Italian culture. The literary productions of the Ragusa epoch were nearly all in verse, chiefly lyrics (modelled after the Italian love-poems), poetic dramas (sacred and profane), epics, and eulogies. The greatest writers were Gundalich (1588–1638), author of the epic *Osman*, which celebrates the war of 1621 between Poland and Turkey; Julius Palmotich (1606–57), a writer of dramas, songs, and epics, most of these last clever imitations of foreign models; Marulich (1450–1524 or 1528), author of the poetic *History* *of St Judith;* Cubranovich (died 1550), author of a celebrated masque, *The Gipsy Girl;* Mencetich-Vlahovich (1457-1501) and Drzich (died 1510), who both excelled in love poems; Lucich (1480-1540), the 'father' of the Ragusan drama; Vetranich-Cavcich (1482-1576), who wrote several mystery-plays; Naljeskovich (1510-87), author of pastorals, comedies, and love-poems; Jorjich (1676-1737), who wrote (like some others of the above mentioned) in Latin, Italian, and Servian, in the last-named tongue chiefly didactic and religious poetry; and Kacich-Miosich (1690-1760), a very popular writer of songs with a good deal of the ring of the national poetry in them.

When the Servians began to awaken, towards the middle of the 18th century, to a renewal of their national life, their literature began to revive at the same time. The man who did most to bring about this revival was Vuk Karadzich (1787-1864): he made the first collection (in 1814-15) of the national songs of the Servians, the greatest literary treasure they possess, encouraged education, codified the laws, collected the fairy-tales and proverbs of his people, translated (1847) the New Testament into the Servian vulgar tongue, effected after a hard struggle a reform of the orthography, prepared a grammar and a dictionary of Servian, and in fact converted the vulgar tongue into a literary language. The best edition of Vuk's *Servian Folksongs* appeared in 6 vols. (1841-66). Several of these have been translated into English by Sir J. Bowring (*Servian Poetry*, 1827) and Lord Lytton (Owen Meredith, *Serbski Pesme*, 1861), neither of remarkable merit, and in another collection by Mrs Mijatovics (*Kossovo*, 1881); into German by Mrs Robinson or 'Talvj' (*Volkslieder der Serben*, 1853); and into Swedish, very well done, by Runeberg (1833). These national songs are the product of different periods and of different, mostly unknown, authors. Their chief themes are the deeds of the national heroes and the occurrences of domestic life. The former class are written in a uniform metre of ten-syllabled trochaics, and are recited to the accompaniment of a simple one-stringed lute. The metre of the second class is varied; they are generally sung by a youth and a maiden. Vuk Karadzich was worthily seconded in his efforts to rekindle the intellectual life of his people in the spirit of patriotic love by Obradovich (1739-1811), who like his compatriot travelled much in south-east Europe, but unlike him was a learned man and a linguist; he spent the whole of his life labouring for the enlightenment of his people. One of the greatest names in modern Servian literature is Milutinovich (1791-1847), who wrote poems, a eulogy on Servia (*Serbianka*, 1826), a *History of Montenegro* (1835), a *History of Servia, 1813-15* (1837), and published a collection of national songs. Raich (1726-1801), who wrote a good *History of the Servian People* (1794-95); J. Popovich (1806-56), the author of lyrics and historical dramas; Lazarevich, who wrote one of the best of Servian dramas (*Vladimir and Kosara*, 1829); J. Subotich (1817-86), author of *Stephan Dechanski* (1846), which has caught the spirit of the national poems; Radichevich (1724-1853), who has been called 'the Servian Burns,' and Prince Peter II. (1813-51) of Montenegro, the two most celebrated lyrists of modern Servian literature; and the Croat Preradovich (1818-72), author of popular lyrics and epics, are the remaining writers of note. Towards the middle of the 19th century an attempt was made on the western side of the Balkan Peninsula to create a sort of revival of the Ragusan period. The centre of the new movement was Agram, and its leader Dr Ljudevit Gaj (1809-72). Its strongest feature was an aggressive sympathy with the Pan-slavist agitation. The language in which the writers of this school composed was the Croato-Servian dialect, but printed in Latin characters; it was, however, renamed Illyrian, chiefly for ethnological and political reasons. Besides Gaj the most important writers of this school were Vraz (1810-51), author of some beautiful lyrics; Vukotinovich, who wrote lyrics and historical tales; Bogovich, from whose pen came dramas, poems, and historical novels; Ivan Mazuranich, whose *Death of Ismail Agha*, the 'epic of hate,' is one of the most popular poems in Servian; and the poets Tomasich and Trnski. Kukuljevich-Sakcinski is the author of poems, dramas, stories, and very valuable historical records of the southern Slavs. Danichich (1825-82) was a first-rate philologist. Jagich and Novakovich have each written a good *History of Servian Literature.* The chief literary organ is the *Glasnik*, published at Belgrade since 1847. In 1880 the Agram Academy began a *Critical Servian Dictionary.*

See an article in the *Westminster Review* for April 1878; Pypin and Spasovich, *Geschichte der Slavischen Literaturen* (vol. i. 1880); A. Dozon, *L'Épopée Serbe* (Paris, 1888); and Mijatovics, *Serbian Folklore* (Eng. trans. by Denton, 1874).

Service (*Pyrus domestica*, the *Sorbus domestica* of many botanists; see PYRUS), a tree of rarely more than 30 feet in height, with leaves and flowers like the Rowan Tree (q.v.), but the former downy beneath. It is by many held to be merely a variety of the rowan produced by cultivation; the chief distinction between the two is in the fruit, which in the service is much larger than in the rowan, and shaped like a small pear. The service has found a place in British floras solely on the strength, it appears, of a single tree having been found in the forest of Wyre near Bewdley, which in all probability had been planted where it stands. On the continent of Europe and in Russian Asia it appears in company with the rowan. It is more cultivated in Italy, Germany, and France than in Britain. The tree is of very slow growth and attains a great age. The timber is valuable, very heavy, fine-grained, and susceptible of a high polish, possessing a strength and durability which particularly adapt it for some purposes of the machine-maker. It is used also for making mathematical rulers, &c. The name Wild Service is given to an allied species, *Pyrus torminalis*, also called the Sorb, a common native of the middle and south of England and of the middle and south of Europe—a small tree with a spotted fruit considerably larger than that of the common hawthorn, which, like the fruit of the true service, becomes mellowed and pleasant by keeping, and is regularly brought to the market in many parts of Europe. Large quantities are brought to London from Hertfordshire. The dried fruit is used in some places as a cure for diarrhœa. The wood is highly valued. It is hard and tough, yellowish white, with brownish-red and dark-brown streaks.



Service Tree (*Pyrus domestica*), branch in flower:
a, fruit, showing section.

Service, Musical. The musical arrangements of a full cathedral service in the Church of England are usually as follows: The introductory prayers of morning and evening service, up to the conclusion of the Lord's Prayer, are sung in monotone. The versicles and responses before the Psalms, after the Creed and Lord's Prayer, and the Litany are sung to the plain-song adapted to them by Marbeck from the equivalents in the Catholic Directory, with some traditional variations; the responses are, however, usually sung in harmony, either in the festal form by Tallis, with the plain-song mostly in the tenor, or in the everyday or ferial form, in simpler harmony. The remaining prayers are sung in monotone, with plain-song inflections and endings. The *Venite* (Psalm xcv.) and Psalms of the day are sung antiphonally to appropriate chants, of which many different collections are in use. Various collections of anthems are also found in different churches. The Canticles (*Te Deum*, &c.) are sung sometimes to chants, but usually to special settings by the various English writers from Tallis downwards; the term 'service' is used as denoting a complete set of music for these parts of the ritual, and is distinguished by the composer's name and the key. An ordinary Morning Service consists of settings of the *Te Deum* and *Jubilate*, or its alternative the *Benedictus*. The *Benedicite* is seldom sung. An Evening Service contains settings of the *Magnificat* and *Nunc Dimittis*, or more rarely of their alternatives the *Cantate Domino* and *Deus Misereatur*. A Communion Service includes choral settings of the *Kyrie Eleison* (the response after each of the Ten Commandments), the Nicene Creed, the *Sanctus* and the *Gloria in Excelsis*, and recent composers add the Doxologies before and after the Gospel, the *Sursum Corda*, the *Agnus Dei*, and the *Benedictus*. The style of music of a service (in the latter restricted meaning) varies very considerably with the different periods to which the composers belong. Among the most eminent of these are Thomas Tallis (*c.* 1515–85), Orlando Gibbons (1583–1625), John Blow (1648–1708), Henry Purcell (1658–95), William Croft (1677–1727), William Boyce (1710–79), Thomas Attwood (1765–1838), and Samuel Wesley (1766–1837). The style of the last has been largely followed by the innumerable modern writers, many of high excellence. See the collections of Boyce, Arnold, Rimbault, and Ouseley, containing also biographical notices. There are also what are known as Chant Services, the music of which is a free form of chant, of which the well-known 'Jackson in F' is a hackneyed example. See also Stainer's *Cathedral Prayer-book* (Novello).

Servile Wars. See Rome, Vol. VIII. p. 790, and Spartacus.

Servites, the common name for the order of the 'Religious Servants of the Holy Virgin,' founded in 1233 by seven Florentine merchants, who soon removed to Monte Senario, 9 miles from the city. They adopted the rule of St Augustine, with many modifications, receiving papal sanction in 1255; and in 1487 Innocent VIII. bestowed on them all the privileges of the other mendicant orders. Before the death of the founders there were 10,000 members of the order. In England there were no houses before the Reformation, but there is now one in London, with a branch at Bognor, and three convents of Servite nuns. The habit is black.

Servitude is a burden affecting land or other heritable subjects, by which the proprietor is either restrained from the full use of his property or is obliged to suffer another to do certain acts upon it, which, were it not for that burden, would be competent solely to the owner (Erskine, *Inst.* II. ix. 1). The name is borrowed from the Roman law, and most of the rules regulating this class of rights in the countries of western Europe are derived more or less directly from the same source. In the Roman law, as now, servitudes are either predial or personal. Predial or real servitudes are those constituted over one subject or tenement in favour of the proprietor of another subject or tenement. It is only as owner of the property that a person enjoys the predial servitudes accessory thereto; and when the property is transferred the servitudes pass along with it. The tenement in respect of which the servitude is enjoyed is called the dominant tenement, and its owner the dominant owner; while the tenement in or over which the right is exercised is called the servient tenement. There is thus always a right on the one side and a corresponding obligation on the other. The term servitude in Scotland is used equally to express the right and the obligation; but the term Easement (q.v.), which is the nearest English equivalent, more generally expresses only the right. Personal servitudes, on the other hand, are those constituted over any subject in favour of a person in his own right, and not as owner of another subject. In Scotland the only rights that have been classed under this head are the different kinds of usufruct or liferent. Real or predial servitudes, which are really the only proper servitudes, were divided in Roman law into urban and rural—the former including all servitudes connected with buildings wherever situated, the latter all those relating to land uncovered by buildings, whether situated in town or country. Rural servitudes comprise rights of road or way, of driving cattle to water, of pasturage, of fuel, feal and divot, as well as several minor rights of bleaching or of taking away sea-ware, stone, slate, sand, or gravel from the ground of the servient subject. Urban servitudes comprehend such rights as eavesdrop or stillicide, support, and light, air or prospect. Both Scots and English law have taken from the Roman law another division, very useful in practice, of servitudes or easements into two principal classes, which are termed positive and negative. By a positive servitude the dominant owner is entitled to perform some act, affecting the servient tenement, which, but for the servitude, the servient owner could have prohibited; thus, all the rural servitudes above mentioned are positive. By a negative servitude the owner of the servient tenement is prohibited from the exercise of some natural right of property—as where he is prevented from building on his own land to the obstruction of light.

Positive servitudes are constituted by grant, recorded or unrecorded, where the consent of the party burdened is expressed in writing, holograph or tested; or by prescription—i.e. by acquiescence in the use of the servitude for forty years. A servitude acquired by prescription is, however, limited by the measure or degree of the use had by him who prescribes. Positive servitudes may also be constituted by implied grant; e.g. in the case of a severance of one property into two distinct properties, such servitudes as are necessary for the convenient and comfortable enjoyment of the respective properties are held to be granted by implication. Negative servitudes, on the other hand, can be constituted only by a formal written grant.

In all servitudes the benefit is confined entirely to the dominant tenement; but the owner of such tenement must exercise his rights *civiliter*, and in the way least burdensome to the servient tenement. The servient proprietor must do nothing to diminish the use or convenience of the servitude; and the dominant proprietor is entitled to access for doing, at his own cost, any work which may be necessary for the proper use or preservation of the servitude. Servitudes are extinguished by express release or the renunciation of the right in a holograph or tested writing; by implied release, as the extinction of either the dominant or servient tenement; by the two tenements being merged into the property of one person; or by nonuser, prolonged for the prescriptive period, so as to imply abandonment. See EASEMENT.

Servius, a commentator on Virgil and one of the most intelligent of the Latin 'grammatici,' lived at Rome about 400 A.D. But much of what is ordinarily cited as his work is by later hands.

Servius Tullius, the sixth king of Rome (q.v., Vol. VIII. p. 781, 787).

Sesame, an annual herbaceous plant of the genus Sesamum, natural order Bignoniaceæ, sub-order Pedaliaceæ, a sub-order characterised by wingless seeds, and placentæ with woody lobes attached to the inner wall of the fruit. The calyx of Sesamum is five-parted; the corolla irregular five-parted; the stamens four, two longer than the others, and a rudimentary fifth stamen; the capsule is oblong, almost four-celled, two-valved, many-seeded. The species most worthy of notice is *S. indicum*, sometimes identified with and sometimes distinguished from *S. orientale*, a native of India. Sesame is cultivated throughout the East from Egypt to Japan for the sake of the seeds, which yield by expression *gingili-oil*. The oil is used in cookery—as a substitute for butter in the same way as olive-oil—for lighting, and for the purposes of lubrication. It is inodorous, has a sweet taste, and keeps for years without becoming rancid. In Egypt and Arabia it is preferred to olive-oil. It is used in connection with medicine. Egyptian women consider it the best of cosmetics and the most perfect preservative of the hair. Nine pounds of the seeds yield two quarts of the sweet oil. The sweet oleaginous seeds are used in some countries, as in Central Africa, for making a kind of hasty-pudding. The oil-cake, mixed with honey and preserved citron, is an oriental luxury. The leaves of Sesame abound in a gummy substance, which they readily impart to water, making a rich bland mucilage, which is used in the southern parts of the United States (where it is grown a little) as a demulcent drink. Sesame is sometimes called *til-seed*.

Sesamoid Bones are small bones met with in the substance of tendons in the neighbourhood of certain joints. They derive their name from their resemblance to grains of sesame. In the human subject the patella is the best example; and besides it they are commonly met with on the palmar aspect of the joint which unites the metacarpal bone of the thumb with the first phalanx, and in the corresponding position in the great toe, there being two in each position, and their object to increase the leverage of the short flexor muscles of the thumb and great toe. They are much more numerous in the great majority of mammals than in man.

Sesostris, the Greek name of a celebrated Egyptian monarch, whose name has passed into the series of those conquerors who have almost achieved universal empire. According to the Greek legendary history, Sesostris at the head of a large army invaded Libya, Arabia, Asia (penetrating farther east than Darius), Europe, Thrace, and Scythia, leaving a colony at Colchis on his return. In the south he subdued Ethiopia, and, placing a fleet on the Red Sea, conquered the adjacent isles, and extended his dominions to India itself. He brought back with him large numbers of captives, who were employed on public works, the building of temples, and the construction of canals and mounds. Memorials of his reign were left as steles or tablets in the conquered countries; Herodotus saw some in Palestine, which in reality are supposed to have been the tablets of Rameses II. Sesostris is said to have grown infirm and blind after a reign of thirty-three years, and to have ended his days by his own hand. There has always existed the greatest divergence of opinion amongst historians as to the identity of Sesostris. Herodotus places his reign long before that of Cheops of the 4th dynasty. Dicæarchus makes him rule 3712 B.C., and is followed by Aristotle and other authors. Bunsen supposes that there were more than one monarch of this name, and that one was a king of the 3d dynasty, another a king of the 12th dynasty. Lepsius conjectures that his exploits are confused reminiscences of Sethos I. and Rameses II. of the 19th dynasty—the most reasonable explanation.

Sessa, a city of Southern Italy, 32 miles NW. of Naples, has a fine cathedral, a theological seminary, a technical college, and ruins (amphitheatre, baths, &c.) of the ancient *Suessa Auruncorum*. On its hills was grown the famous Falernian wine of the Romans. Pop. 5319.

Sessions. See JUSTICE OF THE PEACE, QUARTER SESSIONS, COURT OF SESSION.

Sestertius, a Roman coin, was the fourth part of the *Denarius* (q.v.), and thus contained at first 2½ *asses* or *libræ*. The symbols for it were indifferently HS or IIS, the former being only a modification of the latter, which expresses two units and S for the additional half-unit (*semis*). In the Latin classics the phrase *sestertius nummus*, or merely *nummus*, is frequently employed to denote this coin. When the denarius was made to contain 16 *asses* the relation between it and the sestertius was preserved, and the latter from that time contained 4 *asses*. Till the time of Augustus, when the relation of the denarius to the *as* was changed, the sestertius was worth fully 2d., but after this about an eighth less. *Sestertium* (before Augustus = £8, 15s. sterling) came to be used as if a neuter singular for 1000 sesterces; but with a numeral adverb attached, as *decies sestertium*, was used to signify 100,000 sesterces. It was the 'money of account' (never a 'coin') used in the reckoning of large sums. HSX = *decem millia sestertium*; HS|X| = *decies sestertium*.

Sestos. See ABYDOS.

Sestri Ponente, a suburb of Genoa, 3½ miles to the west, has shipbuilding-yards, machine-shops, and manufactories of tobacco, leather, &c., and in the neighbourhood alabaster mines. Pop. 10,686.

Sethites, or SETHIANS, a division of the Ophites (q.v.), described by Hippolytus, and so called either from the part played by Seth in their cosmogony or from the fact that their doctrines were taught in a book bearing the name of Seth.

Seton, in Surgery, is an artificially produced sinus or channel, through which some substance—e.g. a skein of cotton or silk, or a long flat piece of india-rubber or gutta-percha—is passed so as to excite suppuration, and to keep the artificially formed openings patent. (The term is, however, very often employed to designate the inserted material.) Setons are established in the subcutaneous tissue of the body (1) as counter-irritants, or (2) to act as a drain on the system at large. For the purposes of counter-irritation setons are usually inserted in the neighbourhood of the affected parts; but when intended to act as a drain on the system at large—e.g. in threatened head-affections—the nape of the neck is the part always selected. The operation is very simple. A longitudinal fold of skin over the spines of the cervical vertebræ is raised by the fingers from the deeper structures, and is transfixed by the seton-needle rather obliquely, so that one of the openings shall be rather more dependent than the other. The needle must pass somewhat deeply through the subcutaneous tissue, as if it passed immediately beneath the skin the latter would probably slough over the whole track of the wound. The inserted material should be smeared with oil, and may be allowed to remain undisturbed for four or five days, till there is a free discharge of matter, after which a fresh portion should be drawn daily through the wound. The word *seton* is derived from the Latin *seta*, 'a hair,' because hairs were originally employed as the inserted material. Indeed at the present day it is the custom of many of the nomadic tribes of central Asia to insert a hair into the heels of their prisoners, which lames them to such an extent as to prevent their escape.

Sette Communi. See VICENZA.

Setter, a breed of dog employed in shooting, where he fills the same vocation as the pointer. The setter is divided into three varieties—the English setter, the Gordon setter, which is native to Scotland, and the Irish setter. There was also at one time a variety known as the Welsh setter, but it is now extinct, and probably never differed widely from the English setter. As early as the 16th century the then Duke of Northumberland owned a dog trained by himself to set game, an idea soon followed by others. For many years, however, the spaniel or any other suitable dog was selected to train to the habit of setting game; and it is not until the beginning of the 19th century that any reliable record of a distinct breed of setting dogs can be found. The English setter is bred from the spaniel probably by crossing with the pointer. Though at one time setters were known of nearly all colours, at the present time the English setter is generally white with red markings, or ticked with black spots known as a 'blue Belton.' The late Mr Laverack of Manchester was greatly instrumental in placing the breed on its present basis; he founded a distinct strain, known as Laverack setters, all bred from one brace of dogs, a strain which has become widely diffused. The Gordon setter was founded by the Duke of Gordon about 1800, by crossing the existing setter with a collie bitch which had been trained to set. The Gordon was originally a black, tan, and white dog, though white has gradually disappeared from the breed. The Gordon setter should now be a rich and glossy black marked with tan on face, chest, and legs. The origin of the Irish setter is unknown, and it is hard to say where the peculiar blood-red colour was obtained. In conformation the three varieties differ very slightly, though the Irish setter is a lighter and more leggy dog than the others. The setter should be a smart and active dog, not built on too heavy a scale; chest very deep, though not wide; shoulders sloping back; and with good strong legs and feet. Each variety of the setter has its admirers, and it is an undecided question which is the best, or if any of them are superior to the pointer. Though the setter can endure much more fatigue and hard weather than the pointer, yet he is more headstrong and requires repeated breaking. The Irish setter is the chief sinner in this respect, but is a splendid dog when properly broken.

Setter, 'Heather Grouse.'

Settle, a little gray town in the West Riding of Yorkshire, on the Ribble, and at the base of the Castlebergh cliff (300 feet), 43 miles NW. of Leeds. Dr Birkbeck was a native. Pop. of parish, 2213.

Settle, ELKANAH, was born at Dunstable, 1st February 1648. He entered Trinity College, Oxford, at eighteen, but soon betook himself to London, to make a living by his pen In 1671 he made something of a hit by his tragedy of *Cambyses*, and the Earl of Rochester and others, to annoy Dryden, loudly hailed him as the superior genius of the two. Rochester got his next tragedy, *The Empress of Morocco*, played at Whitehall by the lords and ladies of the court, and in this way a great run was secured for it when it came before the public. In the insolence of success the author printed along with it a Preface, in which Dryden was severely assailed. In his great satire, *Absalom and Achitophel*, Dryden scourged him with his scorn, and so gave him immortality, if only as a shrieking ghost. Having no real strength of talent, Settle speedily relapsed into obscurity. By writing as poet for the city verses for pageants and festivities, and producing pieces to be acted in the booths of Bartholomew Fair, the some-time rival of Dryden was fain to eke out a wretched subsistence. In his destitute age he was admitted to the Charterhouse, where in 1723 he died, and his works followed, if indeed they did not predecease him.

Settlement, in English law, includes any deed, will, or other instrument by which successive interests are created in the same property, the use or income being given to one person, while the corpus of the property is preserved for his successor. A will is revocable in its nature; a settlement made by deed is irrevocable unless it contain an express power of revocation. See the articles DISPOSITION, ENTAIL, ESTATE, LAND LAWS, HUSBAND AND WIFE; in the last of which the distinction between ante-nuptial and post-nuptial settlements is explained. In Scotland the term settlement includes any general will or disposition to take effect after death. In the United States settlements other than marriage settlements are little in use; and marriage settlements are of less importance, most of the states having long since adopted the principle of the married women's property act. A person is said to have a settlement in a parish when by residence or otherwise he has acquired a claim to be relieved out of the rates if destitute; see POOR-LAWS, p. 315

Settlement, ACT OF. See ELIZABETH (Queen of Bohemia).

Setu'bal (called by the English ST UBES), a seaport of Portugal, stands on the north side of the Bay of Setubal, 17 miles by rail SE. of Lisbon. The harbour is protected by five forts. The town owes its importance chiefly to its trade in wine, sea-salt, and oranges, though fishing is carried on with considerable activity. Setubal is the old Roman *Cetobriga*. In 1755 it suffered severely from the earthquake that devastated Lisbon. Pop. 14,798. Pilgrimages are made to a stalactite cave in a neighbouring mountain. The poet Bocage was born at Setubal.

Sevastopol. See SEBASTOPOL.

Seven was frequently used as a mystical and symbolical number in the Bible, as well as among the principal nations of antiquity, the Persians, Indians, Egyptians, Greeks, and Romans. The origin is doubtless astronomical, or rather astrological—viz. the observation of the seven planets and the phases of the moon, changing every seventh day (see WEEK). As instances of this number in the Old Testament, we find the Creation completed within seven days, whereof the seventh was a day of rest kept sacred; every seventh year was sabbatical, and the seven times seventh year ushered in the jubilee year. The three *Regalim*, or pilgrim festivals (Passover, Festival of Weeks, and Tabernacles), lasted seven days; and between the first and second of these Feasts were counted seven weeks. The first day of the seventh month was a 'Holy Convocation.' The Levitical purifications lasted seven days, and the same space of time was allotted to the celebration of weddings and the mourning for the dead. In innumerable instances in the Old Testament and later Jewish writings the number is used as a kind of round number. In the Apocalypse we have the churches, candlesticks, seals, stars, trumpets, spirits all to the number of seven, and the seven horns and seven eyes of the Lamb. The same number appears again either divided into half (3½ years, Rev. xiii. 5, xi. 3, xii. 6, &c.), or multiplied by ten—seventy Israelites go to Egypt, the exile lasts seventy years, there are seventy elders, and at a later period there are supposed to be seventy languages and seventy nations upon earth. To go back to the earlier documents, we find in a similar way the dove sent out the second time seven days after her first mission, Pharaoh's dream shows him twice seven kine, twice seven ears of corn, &c. Among the Greeks the seven was sacred to Apollo and to Dionysus, who, according to Orphic legends, was torn into seven pieces; and it was particularly sacred in Eubœa, where the number was found to pervade, as it were, almost every sacred, private, or domestic relation. On the many ancient speculations which connected the number seven with the human body and the phases of its gradual development and formation, its critical periods of sicknesses—partly still extant as superstitious notions—we cannot here dwell. The Pythagoreans made much of this number, giving it the name of Athene, Hermes, Hephaistos, Heracles, the Virgin unbegotten and unbegetting (i.e. not to be obtained by multiplication), Dionysus, Rex, &c. Many usages show the importance attached to this number in the eyes not only of ancient but even of our own times, and it is hardly necessary to add that the same recurrence is found in the folklore of every race.—The Seven Champions of Christendom are St George for England, St Andrew for Scotland, St Patrick for Ireland, St David for Wales, St Denis for France, St James for Spain, St Anthony for Italy.—The Seven Churches of Rev. i.-iii. are Ephesus, Smyrna, Pergamos, Thyatira, Sardis, Philadelphia, and Laodicea.—The Seven Deadly Sins are pride, covetousness, lust, anger, gluttony, envy, and sloth.—The Seven Principal Virtues are faith, hope, charity, prudence, temperance, chastity, and fortitude.—The Seven Gifts of the Holy Ghost are wisdom, understanding, counsel, ghostly strength or fortitude, knowledge, godliness, and the fear of the Lord.—For the Seven Free Arts, see ARTS.

Seven Bishops. These were Archbishop Sancroft of Canterbury, and Bishops Ken of Bath and Wells, Lake of Chichester, White of Peterborough, Turner of Ely, Lloyd of St Asaph, and Trelawney of Bristol, who were tried on the charge of publishing a seditious libel, but acquitted (June 30, 1687) amid the greatest popular enthusiasm, the very soldiers cheering even within hearing of the king. Their seditious libel was none other than a petition to James II. against his injunction that the clergy should read his Declaration of Indulgence at divine service, in London on the 20th and 27th of May, in other parts of England on the 3d and 10th of June. The order was obeyed in but four out of the hundred parish churches of London, and by not one in fifty all over England. It is striking that of the Seven all became Nonjurors with the sole exception of Lloyd of St Asaph and Trelawney. See Miss Strickland's *Lives of the Seven Bishops* (1866).

Seven Dolours of the Blessed Virgin Mary, FEAST OF, a festival of the Roman Catholic Church, dating from 1423, and since 1725 celebrated on the Friday preceding Palm Sunday. The 'dolours' or sorrows of the Blessed Virgin have long been a favourite theme of Roman Catholic devotion, of which the pathetic hymn *Stabat Mater* (q.v.) is the best known and most popular expression; and the festival of the Seven Dolours is intended to individualise the incidents of her sorrows, and to present them for meditation. The seven incidents referred to under the title of 'dolours' are (1) the prediction of Simeon (Luke ii. 35; of which, indeed, the whole seven are the fulfilment); (2) the flight into Egypt; (3) the loss of the child Jesus in Jerusalem; (4) the sight of Jesus bearing the cross; (5) the sight of Jesus upon the cross; (6) the descent from the cross; (7) the entombment. The festival is now observed as a 'greater double' (see FESTIVALS). A second one, instituted by Pius VII. in 1814, falls on the third Sunday of September.

Sevenoaks, a pleasant town of Kent, on an eminence 22 miles SE. of London. It has a Perpendicular church with some interesting monuments, the Walthamstow Hall (1882) for 100 daughters of missionaries, and a grammar-school founded in 1432 by Lord Mayor Sir W. Sennocke, incorporated by Queen Elizabeth, and reconstituted as a first-grade modern school in 1877, at which Grote and Bishops Christopher and Charles Wordsworth were educated. Knole, the magnificent seat of Lord Sackville, is close by. It was mainly built between 1460 and 1608 by Archbishop Bourchier and Thomas Sackville, first Earl of Dorset, and has a park of 1000 acres, 5 miles in circumference. Pop. (1861) 3171; (1891) 7514.

Seven Sleepers, the heroes of a celebrated legend, which is first related in the West by Gregory of Tours in the close of the 6th century (*Miraculorum Liber*, c. 92), but the date of which is assigned to the 3d century, and to the persecution of the Christians under Decius. According to the story, during the flight of the Christians from the persecution, seven Christians of Ephesus took refuge in a cave near the city, where they were discovered by their pursuers, who walled up the entrance in order to starve them to death. They fell instead into a preternatural sleep, in which they lay for nearly 200 years. This is supposed to have taken place in 250 or 251; and it was not till the reign of Theodosius II. (447) that they awoke. They imagined that their sleep had been but of a single night; and one of the seven went secretly into the city to purchase provisions, and he was amazed to see the cross erected on the churches and other buildings. Offering a coin of Decius in a baker's shop he was arrested, his startling story not being believed until he guided the citizens to the cavern where he had left his comrades. The emperor heard from their lips enough to convince him of the life beyond the grave of the dead, whereupon they sank again to sleep till the resurrection. Gregory explains that his story is of Syrian origin—it is widely current in the East, and was adopted by Mohammed (*sur.* xviii.), who even admits their dog Kitmer also into Paradise. The Roman Catholic Church holds their festival on June 27. The names usually given are Maximianus, Malchus, Martinianus, Dionysius, Joannes, Serapion, and Constantius. Paulus Diaconus (8th century) locates a similar story in Germany, and Rydberg makes out a good case that the myth is of Teutonic origin intimately connected with the return of the dead Balder and of the other dead men from the lower world, with the idea of resurrection and the regeneration of the world, but possibly enough first Christianised in Syria or Asia Minor. The seven sons of Mimer awakening from their long sleep at the blast of *Heimdal's trumpet* to take their part in the final struggle of the universe is a close parallel to the seven saints of Ephesus. Both in Germany and Sweden the seven sleepers are connected with the weather—if it rains on their day rain will follow for seven weeks together. They are supposed also to take especial care of sailors. See Koch, *Die Siebenschläferlegende* (Leip. 1882); and Rydberg, *Teutonic Mythology* (Eng. trans. 1889).

Seventh-day Baptists. See SABBATH, p. 60.

Seven Wise Masters, the most common title given to a famous mediæval collection of stories, grouped round a central story, the history of which is almost the most important among the problems of storiology. The leading story itself is briefly as follows: A young prince is born in answer to prayer as the only son of the aged king Kûrush, and the astrologers foretell a great danger overhanging his fate at twenty. At seven years he is entrusted to masters, but at thirteen he has not learned anything. The sages then recommend Sindibâd as the best master, but for six and a half more years the young prince studies under him uselessly, and at nineteen and a half he has still learnt nothing. The king again assembles the wise men, and Sindibâd offers to teach the prince everything in six months or forfeit his life. He now shuts himself up with his pupil, who this time succeeds to his master's satisfaction. Before bringing him back Sindibâd consults the stars, and sees that the prince will die if he should speak before seven days. Sindibâd therefore hides himself, and the prince at court is found to be dumb. One of the king's women now tempts him as the wife of Potiphar did Joseph, and in the fury of disappointed rage accuses him to the king of an attempt on her virtue. The king condemns him to death, whereupon the seven viziers resolve to intercede to stay his execution. The first goes to the king, and by two tales against women obtains the suspension of the execution for that day. Next day the woman by a tale of contrary character obtains a confirmation of the sentence; but a second vizier again procures a suspension by two tales; and so on till the end of the seventh day when the prince is free to speak. He now comes to the king attended by the sages and by Sindibâd, whereupon the woman is duly punished, and the king, after seeing proof of his son's wisdom, gives him his throne and retires into solitude to serve God.

Of variant versions there are two principal groups, the Eastern and the Western, the first including all the texts in Eastern languages, and some more or less free translations from Oriental texts; the other including the *Dolopathos*, the *Historia Septem Sapientum*, the *Erasto*, and many others. The Oriental texts have so many elements in common that they obviously spring from one book as a common basis, of which they are more or less faithful translations, at different epochs and in different literatures. The Western texts, though derivable from the Eastern, show great divergencies alike in the fundamental story and in the tales inserted in it. The real cause of this is that in the Western cases *oral* tradition has transmuted the contents.

The earliest version of a *Book of Sindibâd* is found in Arabian writers of the 10th century. The more important Eastern versions are the following: (1) The *Syntipas*, a Greek text translated from the Syriac by Michael Andreopulos during the last years of the 11th century (ed. by Dr A. Eberhard in vol. i. of *Fabulæ Romanenses Græce Conscriptæ*, Leip. 1872). A Syriac text was found by Rödiger, and has been edited, with a German translation, by Dr Baethgen (Leip. 1879). (2) The Hebrew version entitled *Parables of Sandabar* (*Mischle Sandabar*), translated from the Arabic, probably in the first half of the 13th century. There is a German translation by Sengelman (Halle, 1842), a French by Carmoly (Paris, 1849). (3) The *Sindibâd-Nâmeh*, an unedited Persian poem, written in 1375. (4) The eighth night of the *Tûtî-nâmeh* of Nachschebî, a Persian poet who died in 1329. Of this there is a German translation by Professor Brockhaus (Leip. 1845). (5) *The Seven Viziers*, an Arabic text, forming part of some redactions of the *Thousand and One Nights*, of uncertain age, but not ancient. (6) An ancient Spanish translation of an Arabic text existing in a 15th-century codex—the version closest to the *Syntipas*. It was first printed by Comparetti in his *Ricerche intorno al Libro di Sindibâd* (Milan, 1869; Eng. trans. of Comparetti's study and the old Spanish text, Folklore Society issues, 1882).

Western versions exist in the most perplexing variety and number—Latin, French, Italian, Catalan, Spanish, English, German, Dutch, Icelandic, Swedish, Danish, Polish, Russian, Hungarian, and Armenian. The *Dolopathos is a French metrical version supposed to have* been made by Herbert in the reign of Louis IX. from the Latin romance of Jean de Haute-Seille, *Historia de Rege et Septem Sapientibus*. This Latin text (*Johannis de Alta Silva Dolopathos*) was edited by Oesterley (Strasb. 1873); other Latin versions varied widely. A French metrical version was printed by Keller (Tüb. 1836); *Li romans de Dolopathos*, by Ch. Brunet and A. de Montaiglon (1856); two prose versions of the *Sept Sages de Rome*, by Gaston Paris (1876). An English prose version soon followed (middle of 16th century) *under the title of the Seven Wise Masters*, and about the same time a Scotch metrical version by John Rolland of Dalkeith. One English metrical version was printed by Henry Weber (1810), another by T. Wright for the Percy Society (1845). Among Italian versions we have a 13th-century translation from a French prose version, printed by Professor A. d'Ancona (*Il Libro dei Sette Savj di Roma*, Pisa, 1864); the latest is the 16th-century book, *I Compassionevoli Avvenimenti di Erasto*. German versions begin with the metrical rendering of 1412 by Hans v. Bühel, *Diocletianus Leben*, edited by A. Keller (Quedlinb. 1841). A second and anonymous poetical version is given in Keller's *Altdeutsche Gedichte* (Tüb. 1846). The prose *Volksbuch* was first printed in the 15th century, and will be found in Simrock's collection. See Professor Mussafia, *Beiträge zur Litteratur der sieben weisen Meister* (Vien. 1868); Dr Marcus Landau, *Die Quellen des Dekameron* (2d ed. 1884); and W. A. Clouston, *The Book of Sindibād*, from Pers. and Arab. (1884).

Seven Wise Men, the collective designation of a number of Greek sages, whose moral and social experience, according to the ancients, was embodied in certain brief aphorisms. Their names, as usually given, and their characteristic aphorisms are as follows: Solon of Athens—'Nothing in excess;' Thales of Miletus—'Suretyship brings ruin;' Pittacus of Mitylene—'Know thine opportunity;' Bias of Priene in Caria—'Too many workers spoil the work;' Chilon of Sparta—'Know thyself;' Cleobulus, tyrant of Lindus in Rhodes—'Moderation is the chief good;' and Periander, tyrant of Corinth—'Forethought in all things.'

Seven Wonders of the World were in ancient times reckoned to be the Pyramids of Egypt, the Hanging (i.e. terraced) Gardens of Semiramis at Babylon, the Temple of Diana at Ephesus, the Statue of Jupiter at Athens by Phidias, the Mausoleum, the Colossus at Rhodes, and the Pharos of Alexandria. This cycle of seven wonders originated among the Greeks after the time of Alexander the Great, and they were described in a special work by Philo of Byzantium, which has been edited by Orelli (1816).

Seven Years' War, THE, was the third, and by far the longest (1756-63) and most terrible, of the contests for the possession of Silesia (q.v.). During the two former wars the Empress Maria Theresa had been too much engrossed in maintaining her claims to the Austrian dominions to offer any very effective resistance to the aggression of Frederick the Great of Prussia; but after emerging triumphantly from that contest she began to concert measures for the recovery of her lost province. Frederick, however, with his usual astuteness, foresaw her purpose and resolved to anticipate her. Accordingly in August 1756 he made a sudden advance upon Dresden with 60,000 men; and, when the elector refused either to side with him or to promise strict neutrality in the coming struggle, he shut up the Saxon army (17,000 strong) between Pirna and Königstein. An Austrian army, commanded by Marshal Browne, advanced to relieve the Saxons, but was met by Frederick at Lobositz (October 1), and driven back into Bohemia. The Saxons then surrendered (October 14), and were mostly incorporated with the Prussian army, whilst their country was treated by Frederick, in the absence of the elector, who fled to Poland, as a conquered province. This action on the part of Frederick thoroughly roused his enemies, and made them rapidly perfect their alliances; so that, when the second campaign began in the following year, the Prussian king was opposed by 100,000 Russians, more than that number of French troops, and by armies raised by Sweden and the empire. His own armies, including 40,000 Hanoverians, English, and Hessians, numbered less than 200,000. In April Frederick, leaving a corps of 24,000 under Schwaldt to oppose the Swedes and Russians, invaded Bohemia and managed to shut up the Austrian army under Duke Charles of Lorraine in Prague; but Marshal Daun headed another army for the Duke's release, and inflicted a crushing defeat upon Frederick at Kolin (June 18). Meanwhile a large French army under Marshal d'Estrées advanced into Hanover, defeated the incapable Duke of Cumberland at Hastenbeck (July 26), and intimidated him into disbanding, by the Convention of Closter-Seven, the whole of his army excepting the Hanoverians. Another French army under Soubise effected a junction with the Imperialists under the Prince of Hildburghausen in the direction of Saxony; but Frederick turned and smote them at Rossbach, and after half an hour's fighting put them completely to rout. This diversion left the victorious Austrians unopposed, and they soon made themselves masters of Silesia and Breslau. Frederick, however, taught them what stuff he was made of by defeating an Austrian army three times as numerous as his own at Leuthen (December 5), and thereby recovered Silesia. These victories induced the Russians to vacate the province of East Prussia, which they had seized after defeating Lehwaldt at Grossjagersdorf (August 30). The English government, rejecting Cumberland's engagements of Closter-Seven, raised another army for 1758 and put it under the leadership of Duke Ferdinand of Brunswick, who effectually held his own against the French, and even drove them out of Westphalia and beyond the Rhine, defeating them at Krefeld (June 23) and Minden near Frankfort (August 1, 1759). The king of Prussia had in the spring of 1758 pushed into Bohemia, but could make no headway before he was called back northwards to meet the Russians, who had invaded Brandenburg. He defeated them in a desperate battle at Zorndorf (August 25). At this time Frederick's brother, Prince Henry, was being hard pressed in Saxony by Daun with superior forces, and the king, the Russians being in rapid retreat for Poland, sped back to his help. Daun, however, contrived to take Frederick completely by surprise, and gave him a terrible beating at Hochkirch (October 14). Nevertheless, before the end of the year the Prussians were again in possession of Saxony.

The fourth campaign (1759) in the east of Prussia was altogether disastrous to the Prussians. The king was not able to carry out his desire of hindering the conjunction of his enemies, the Russians and Austrians, first through the defeat of his general Wedell near Zullichau (July 23), and then through his own terrible losses against the allied armies at Kunersdorf (August 12). Three months later Daun compelled a Prussian force under General von Finck to capitulate at Maxen in the south of Saxony, and thereafter established himself in that country. With greatly diminished strength, an exhausted treasury, a desolated territory incapable of affording either men or supplies, and gloomy forebodings of the final issue, though with unfaltering resolution never to yield, Frederick prepared for the fifth campaign (1760). His army in Prussia, now reduced to 90,000 men, mostly foreigners and raw recruits, was still further diminished by the capture of Fouqué with 8000 men in Silesia, followed by Marshal Loudon's conquest of that province, though by the brilliant victory of Liegnitz (August 15) Frederick successfully prevented the Austrians and Russians from uniting their forces. In spite of this his strength was now becoming ominously insufficient for the task he had set himself; the Russians and Austrians captured and plundered Berlin (October 1), the Swedes came down from the north, and Loudon closed in upon the king from Silesia. But he fell with incredible fury upon Daun at Torgau in Silesia (November 3), slew 12,000 of his men and took 8000 more prisoners, and by the retreat of the Austrians was once more left in possession of Saxony. In the following year (1761) the French were again worsted by Duke Ferdinand at Villinghausen (July 15). In Silesia Frederick as usual attempted, but in vain, to prevent the Austrians from joining the Russians, and only found relief when scarcity of provisions compelled the Russians to retreat to Poland. Loudon, however, captured Schweidnitz, whilst farther north the Russians and Swedes drove the Prussians out of Pomerania. To add to Frederick's difficulties, all subsidies from Britain were stopped by the Earl of Bute after George II.'s death, and Prussia was utterly at the end of her resources of all kinds.

But suddenly the death of the czarina Elizabeth (January 5, 1762) freed him from one of the most powerful of his enemies. At the same time the new czar (Peter III.) induced Sweden to retire from the war. Thereupon Frederick took up the contest with renewed vigour; on July 21 he stormed the

Austrian entrenchments at Burkersdorf, and, following up this success, routed Daun at Reichenbach (August 16) and took Schweidnitz (October 9), thus recovering Silesia. Contemporaneously with these events his brother, Prince Henry, by a series of fortunate manœuvres possessed himself of the passes of the Erzgebirge, and overthrew the imperial forces at Freiberg (October 29). In the west the Duke of Brunswick still held his ground gloriously against the French, routing them at Wilhelmsthal (June 24), capturing Cassel, and recovering the whole of Hesse. France now gave up a contest from which she had gathered nothing but military disgrace, and concluded treaties with Britain and Prussia; and towards the end of the year the minor German states also withdrew from the coalition. Maria Theresa was now left alone, and, Austria being exhausted as well as Prussia, was compelled, sorely against her will, to conclude the peace of Hubertsburg (February 15, 1763; England made peace with France by the treaty of Paris on the 10th), which finally acknowledged Frederick as the lord of Silesia.

This long and desperate struggle cost Europe a million lives, and prostrated the strength of almost all the powers who had engaged in it. It made no change in the territorial distribution of Europe, but it increased tenfold the moral power of Prussia, and gave its army a prestige which it retained till the battle of Jena. But outside of Europe, in North America and India, it brought about a new epoch. According to Parkman, it crippled the commerce of France and blighted her colonial power; it gave England the mastery of North America and India, and made her the first commercial nation.

See Carlyle's *History of Frederick the Great*; Frederick II., *Histoire de la Guerre de Sept Ans*, and histories by Auchenholz (11th ed. 1879), the officers of the Prussian General Staff (8 vols. 1827-47), Maslowski (Russian account; Ger. trans. Berlin, 1888 *et seq.*), Longman (in 'Epochs of History' series), and H. Lloyd (2 vols. Lond. 1781-90); also the article FREDERICK II. And for America and India, see Parkman, *Montcalm and Wolfe* (1884); Seeley, *The Expansion of England* (1883); and the articles CANADA, CLIVE, COLONY, HAWKE, INDIA, WOLFE.

Severalty. An estate in severalty is held by one owner, without being joined with others having common interests, as opposed to Coparcenary (q.v.), Joint-tenancy, and Tenancy-in-common. In the Indian legislation of the United States land in severalty is that allotted to individuals which was once held by the tribe. In English law a contract of several persons is joint and not several—i.e. one cannot be sued separately, but they must all be sued together—unless the words 'we jointly and severally promise' are introduced into the contract, promissory-note, &c. In Scotland the general rule is the reverse; in a *conjunct* contract each is liable for the whole.

Severn (Lat. *Sabrina*), one of the most important and beautiful and, after the Thames, the largest of the rivers of England, rises, 1500 feet above sea-level, from a chalybeate spring on the eastern side of Plinlimmon, 12 miles west of Llanidloes, in Montgomeryshire, North Wales. Flowing eastward from its source to Llanidloes, to which town it retains its original British name of Hafren, it afterwards flows north-east past Newtown (465 feet) and Welshpool to the eastern boundary of Montgomeryshire, then east-south-east past Shrewsbury and Bridgnorth in Salop, and finally southward through Worcester and Gloucester, in which last it begins to form the estuary that merges in the Bristol Channel (q.v.). It is navigable for barges to Welshpool in Montgomeryshire, 180 miles from its mouth. Its entire length is 210 miles (though the distance from source to mouth as the crow flies is only 80), and it drains an area of more than 6000 sq. m. The chief affluents of the Severn are the Terne and the Upper and Lower Avon on the east, and the Teme and Wye on the west. A canal 18½ miles long, and navigable for vessels of 350 tons, extends from Gloucester to the upper portion of the estuary of the river, and thus materially shortens the navigation of its lower course; and in the summer of 1891 works were undertaken, to cost £30,000, for the improvement of the navigation to Worcester. The Montgomery Canal extends from Welshpool to Newtown, and other canals establish communication between the Severn and the Thames, Trent, Mersey, and the other important rivers of the middle districts of England. In some of the reaches below Gloucester, especially near Newnham, the tide, which flows with great velocity, produces from the peculiar configuration of the estuary a bore (locally termed *hygre*) or wave sometimes 5 or 6 feet high, which not infrequently overwhelms lighters navigating the river. The railway twice crosses the estuary—near Berkeley by a viaduct (1879), 1194 yards long, and near Chepstow by a tunnel (1873-85), 4⅓ miles long.

Severn, JOSEPH (1796-1879), an artist chiefly known as the faithful friend of Keats (q.v.). From 1861 to 1872 he was British consul at Rome. See Sharp, *The Life, Friendships, and Letters of Joseph Severn* (1892).

Severo, CAPE. See CHELYUSKIN.

Severus, L. SEPTIMIUS, a Roman emperor and a soldier of great vigour and courage, was born of equestrian rank, near Leptis Magna in Africa, 146 A.D. He became prætor at Rome in 178, and was at length appointed to the command of the army in Pannonia and Illyria. After the murder of Pertinax (193) he was proclaimed emperor at Carnutum, and promptly marched upon Rome, where the puppet Julianus had by purchase obtained the imperial purple. His arrival before Rome was the death-signal for Julianus; and after taking vengeance on the murderers of Pertinax, converting his most formidable rival, Clodius Albinus, into an ally by creating him Cæsar, and distributing an extravagant largess to his soldiers, he marched against his second rival, Pescennius Niger, and conquered him at Issus (195). A glorious campaign in the East, and the three years' siege and capture of Byzantium, were followed by a desperate struggle with his jealous rival, Clodius Albinus, whom, after an obstinate conflict near Lyons, he conquered (197). After the usual games to the degenerate citizens of Rome and largesses to the troops, Severus returned to Asia, accompanied by his sons Caracalla and Geta, had the most brilliant success in the campaign of 198 against the Parthians, and took and plundered their capital, Ctesiphon. He returned to Rome in 202, and gratified the popular taste by the exhibition of shows of unparalleled magnificence, also distributing another extravagant largess to the citizens and prætorians. A rebellion in Britain drew him thither in 208, and at the head of an immense army he marched, it is said, to the extreme north of the island, encountering enormous hardships. To secure to some extent the natives of South Britain from the incursions of the Meatæ and Caledonians, Severus repaired or partially built the wall which is often called after him, and died soon after at Eboracum (York), 4th February 211. Some recent authorities believe that the wall has as much right to bear his name as that of Hadrian; see HADRIAN'S WALL, and G. Neilson's *Per Lineam Valli* (Glasgow, 1891).—For the emperor ALEXANDER SEVERUS, see that article.

Sévigné, Madame de, the queen of letter-writers, and one of the most charming figures in the literature of France, was born at Paris of an ancient Burgundian family, February 6, 1626. Her maiden name was Marie de Rabutin-Chantal, and she was the second and only surviving child of her parents. Her father's mother had entered a convent under the advice of Saint Francis de Sales, became founder of the Order of the Visitation, and was afterwards canonised. When the child was but one year old her father fell fighting against the English at Ré; a few years later her mother followed, leaving her to be brought up at Livry by her maternal uncle, the Abbé de Coulanges, the 'Bienbon' of her life-long affection. She received a careful education under Ménage and Chapelain, and learned Latin, Italian, and Spanish. From her childhood she saw clearly the whole comedy of life, and all her days she was 'une grande dévoreuse de livres'—history, Virgil, Plutarch, Tacitus, Nicole, Montaigne, and even Rabelais. At eighteen (August 4, 1644) she married the young and handsome Marquis Henri de Sévigné, the head of an ancient family of Brittany, but unfortunately for her happiness a spendthrift and a libertine. Her daughter Françoise Marguerite was born at Paris, October 10, 1646; her son, Charles, at her famous country-house, the Rochers, in 1648. She loved her husband in spite of his infidelities and indifference; forgave him even his passion for Ninon de Lenclos, who lived to cast for a moment the same evil spell upon her son; and when he was killed in a duel by a rival in a more sordid intrigue (February 5, 1651), mourned him sincerely, yet forgot him so completely that in the long correspondence of later years with her children she does not once mention his name. Madame de Sévigné at the moment of her widowhood was but twenty-five, brilliant in her beauty and fascination; yet without hesitation she embraced that holy vocation of undivided motherhood to which she was to give such complete and exquisite expression. Her handsome figure, splendid complexion, fair, wavy hair, and brilliant eyes are spoken of by all who have described her; but her beauty was more that of expression than of feature, and she herself has told us that her nose was somewhat square, her blue eyes ill-matched (*bigarrés*). Her portraits are not satisfactory, and do not give the idea of beauty, but doubtless her charm was of that subtle kind that eludes the painter. After about a year's retirement at the Rochers she returned to society, but all the flatteries of the most brilliant court in the world failed to touch her heart. The Prince de Conti, Turenne, Fouquet the *Surintendant* of Finance, Rohan, and her cousin Bussy-Rabutin (1618-93) sighed for her in vain; and, stranger still, in the midst of that age of gilded corruption, her name remains without a stain. She was virtuous by temperament, with warmth only in the intellect, says Bussy in his malicious portrait of her; but the intended sneer recoils upon himself, as if it were no virtue for that warm heart and impulsive temperament to be virtuous! Her heart was entirely occupied by a purer love—an intense devotion to her children, and a warmth of friendship almost beyond example. For no one ever had so many and such devoted friends—no woman ever knew like her how to transform a lover into a friend. La Rochefoucauld said she fully satisfied his ideal of friendship, and Madame de la Fayette said, almost at the close, after forty years of friendship without a cloud, 'Croyez, ma très chère, que vous êtes la personne du monde que j'ai le plus véritablement aimée.' The real secret of this affection was her own goodness, which is reflected on every page of her letters; even the follies of her friends she touches with a light hand; her wit never stings, she has a charitable interpretation for everything. Her sweet and happy temper played lightly even with sorrow and wrong-doing. She was pure in an age when purity was rare, and if she had a single fault it is that she was merely something too lenient in her tolerance. She was a genial optimist, not from general indifference, but from love, for her friendships made a real part of her existence. The graphic letters to Pomponne describing the trial of Fouquet prove a noble fidelity of heart that defies misfortune and disgrace. Some of her own letters, discovered among the fallen surintendant's papers and read by the king, caused for a moment much talk and scandal, in allaying which Bussy did his cousin a good service. Yet furtively he had done her a grievous wrong. Having been in difficulties about 1656 he had applied to her for a loan of 10,000 écus (£2400), but, some delay being occasioned by Bienbon's desire to look into the securities, he took offence, found the money from the Marquise de Montglas, and, during the enforced solitude of a short banishment to his country-house for some scandalous impieties, wrote a few satirical sketches of the courtiers for the amusement of this mistress—the *Histoire amoureuse des Gaules*. In this unclean company a cruel and lying description of Madame de Sévigné was inserted, and when the book was printed at Liége (1665), without Bussy's knowledge, she had the mortification to find herself in the mouths of all the scandal-mongers of the day. Bussy was arrested on the 17th April, imprisoned in the Bastille for thirteen months, and sentenced to banishment from Paris for seventeen years. It needed only to be unfortunate to ensure the sympathy of Madame de Sévigné, and the reconciliation, which was complete by 1668, perhaps left the repentant Bussy, says Mesnard, 'with a more tender and serious feeling than he had ever experienced in his life before.' She herself invented the word *Rabutinage* to express the family ties and the common sympathy which substantially bound the two together.

Meantime her daughter had grown up with a beauty, if not a personal charm, that far surpassed her mother's, and Madame de Sévigné's heart was filled with joy at the sensation made by 'the prettiest girl in France' on her first appearance at court in the winter of 1662-63. In January 1669 she married François Adhémar, the Comte de Grignan, then Lieutenant-général of Languedoc, but ere the close of the year, of Provence—an office which obliged him at once to leave Paris. He had been twice married already, was thirty-seven, of ancient race, honourable in his life and dignified in manners, but he was overwhelmed in financial difficulties which were yet to cause much trouble to Madame de Sévigné. The great grief of her life was this separation from her much-loved daughter, but it is mainly to it that we owe those letters extending, with intervals of union (longest as well as most frequent between 1677 and 1688) over the twenty-five years until her death. Bussy and Saint-Simon say that the daughter lacked heart, and it is at least certain that she was proud, shy, and uncommunicative to the outer world. But she really loved her mother, and never failed, except when ill, to write to her twice a week throughout all the years of separation. It is unfortunate for her that these letters have been destroyed, and probably also, as Sainte-Beuve suggests, her mother has harmed her somewhat in our eyes by praising her too much. She seems cold by contrast with her mother's overflowing affection, but it is impossible in the nature of things that so much love as Madame de Sévigné's could have been lavished without forcing a return. Her love was accompanied by all the doubts and fears that are the characteristic marks of another form of human emotion; and its exceptional intensity cannot be understood unless we remember how it came to fill her heart at a moment when the dear illusion of a husband's love had been rudely shattered for ever. 'Vous ne comprenez point encore trop bien l'amour maternel: tant mieux, ma fille, il est violent,' she writes. Its iteration has deterred many a reader at the outset, as it long did so fine and sympathetic a spirit as Edward FitzGerald. Yet he lived to take her altogether to his heart, and he thus ends a letter with a personal touch of pathos worthy of herself: 'I sometimes lament I did not know her before; but perhaps such an Acquaintance comes in best to cheer one toward the End.'

At fifty her splendid health was first shaken at the Rochers by a violent fit of rheumatism; thereafter till the close her only troubles were her son-in-law's vast expenditure and ever-increasing debts, and one by one the deaths of her dearest friends. Her life wore itself away in a round of duties at Paris, at the Rochers, and in visits to the country-houses of her friends and to her daughter in Provence. Nothing in her was more wonderful than her adaptability of disposition; she is happy alike by the bedside of a sick friend, in her drives with Madame Scarron, soon to be virtual queen of France, in the society of the court, and alone under the dense leafage of her park at the Rochers. One thing only we would have had otherwise than it is, but it would be a complete anachronism to ask for more sympathy than she has to show for the miserable Breton peasants under the cruel campaign of 1675. Her son Charles had some follies which cost money, before his marriage (1683); but he stands out an attractive figure enough, generous and warm-hearted, content with an unequal half of his mother's heart. Bienbon died in 1683; Bussy and Madame de la Fayette in 1693. Her letters grow sadder as she begins to find herself alone, yet some of the latest stand among the first in literary value. She never grew old, for her heart retained its warmth; yet she lived to see son and grandson married, and after nursing her daughter through a tedious illness was herself attacked by smallpox, and died calmly and without fear, 18th April 1696.

Madame de Sévigné's twenty-five years of letters to her daughter reveal the inner history of the time in wonderful detail, but the most interesting thing in the whole 1600 (one-third letters to her from others) remains herself. She was genuinely religious without superstition, a strong sympathy with Port-Royal manifest throughout; she had read widely and gained much from conversation, and she had lived in the time of Pascal, Molière, Racine, Bossuet, and La Rochefoucauld. Still more, she possessed the great natural gifts of a solid understanding and strong good sense. But it needed the warm touch of affection to make all these qualities live, and to give her letters the freedom, the rapidity, the life of spoken words. Hence her sparkling wit, her swiftly changing emotions, her unstudied yet admirable phrase, clear, firm, and natural, the tenderest sentiments and gayest flights of fancy ever expressed with unfailing grace and the indefinable charm of style. Her imagination, warmed by sympathy and love, realises the conditions of those to whom she writes, and enables her to enter into the thoughts of others, as well as to reflect as in a mirror the world around herself. Yet over all there is a gravity and reserve characteristic of that stately and ceremonious age. She never once *thous-and-thees* anybody; a certain dignity remains even in the most intimate relations. The perfection of her letters was from the first moment recognised, and the question has often been asked did that piquant grace of detail, that charming variety in the repetition of the same thoughts, cost her pains. No doubt she knew she wrote well, however little she thought of fame, yet this knowledge did not exclude sincerity, and she must have written fast to have written so much—'Je fais de la prose avec une facilité qui vous tue,' she says. And she does not write alike to all people; to Bussy and the sprightly Mme. de Coulanges there is a little restraint: to her daughter it is heart to heart, now private affairs and prattle about her neighbours, now matters of state and the graver questions of life and death, written with swift-flowing pen for her eye alone. We may love Madame de Grignan only for her dear mother's sake, yet we owe to her an inestimable debt of gratitude, for it was her care that preserved the precious letters of Madame de Sévigné, and bequeathed them to the endless affection of posterity.

The earliest of her letters that were published were those to Bussy, printed in his *Mémoires* (1696-97). The first edition of the *Lettres* was printed in 1726 by Bussy's son, the Abbé de Bussy, to whom her granddaughter Pauline (Madame de Simiane) had given transcripts of the originals. A more complete edition, authorised by the family, was the final one of those edited by the Chevalier Marius de Perrin (8 vols. 1754). Further editions were innumerable—three only need be mentioned, those of the Abbé de Vauxcelles (1801), Gouvelle (1806), and M. de Monmerqué—an abiding monument of patient industry (10 vols. 1818-19). The final edition is, however, that in the 'Grands Ecrivains de la France,' begun by M. de Monmerqué, and finished by A. Régnier, Paul Mesnard, and E. Sommer (14 vols. 1865-67; vol. i., with Mesnard's life; vols. xiii.-xiv. a Lexique by Sommer), especially as supplemented by Ch. Capmas in *Lettres inédites de Madame de Sévigné* (2 vols. 1876). See Walckenaer, *Mémoires touchants la Vie et les Ecrits de Madame de Sévigné* (5 vols. 1842-52; vol. vi. by Aubenas, 1865); the Comtesse de Puliga, *Madame de Sévigné, her Correspondents and Contemporaries* (2 vols. 1873); the admirable studies by Miss Thackeray in 'Foreign Classics' (1881) and Gaston Boissier in 'Les Grands Écrivains Français' (1887), as well as those by Combes (1885) and Vallery-Radot (1888); Léon de la Brière's *Madame de Sévigné en Bretagne* (2d ed. 1882); and Saporta's *La Famille de Madame de Sévigné en Provence* (1889). See also Sainte-Beuve's *Portraits de Femmes, Causeries du Lundi* (vol. i.), and *Nouveaux Lundis* (vol. i.); E. Scherer's *Etudes sur la Litt. Contemp.* (vols. ii. and iii.), and chapter 6 of Amelia Gere Mason's *Women of the French Salons* (1891).

Seville, one of the most famous of Spanish cities, stands on the left bank of the Guadalquivir, 62 miles (95 by rail) N. by E. of Cadiz, and is connected with a large suburb (Triana) on the right bank by an iron bridge (1848). It has had two periods of great splendour in its history, first as the capital of a Mohammedan emirate, and later in the 16th and 17th centuries as the headquarters of Spanish painting and the chief port of Spanish commerce; and it is now rapidly recovering a good deal of its former commercial prosperity, the river Guadalquivir being navigable for large vessels (of 16 feet draught) up to the city. Until quite recently Seville had the appearance of a picturesque Moorish town—the streets narrow, tortuous, and shady, the houses built round handsome court-yards and gardens, the squares studded with fountains. But during the last few years the city has been greatly modernised by the clearing away of the narrower quarters to make room for wide straight streets and modern houses and shops. Only a few fragments now remain of the former circular city wall, which was adorned with sixty-six towers. The water-supply was formerly brought from Alcalá de los Panaderos by an old Roman aqueduct of 410 arches, but this has been superseded by new waterworks constructed by Englishmen in 1883. The greatest ornament of the city is the vast Gothic cathedral, built in 1401–1519 on the site of a Moorish mosque. It is one of the largest in Europe, and contains valuable paintings by Murillo (a native of Seville), Valdés Leal, De Vargas, and other masters; magnificent Flemish stained glass of the 16th century; one of the largest organs in the world; the tombs of King Ferdinand III. of Castile, Ferdinand the son of Columbus, and other notabilities; and much most excellent artistic work in bronze, wood-carving, and sculptured work. Close beside the cathedral stands the beautiful Campanile (q.v.) called Giralda, 275 feet high. Both cathedral and tower were seriously damaged by an earthquake in 1884; the latter was soon afterwards restored by the government of Spain and the queen, but in the case of the former the injury done to two of the main piers has not yet been repaired. Another of the glories of Seville is the Alcazar, or Moorish royal palace, begun in the end of the 12th century, and considerably enlarged and beautified by Peter the Cruel; its halls and gardens are surpassed only by those of the Alhambra. Amongst the other interesting buildings and public institutions of the city must be mentioned the House of Pilate built by a Spanish nobleman in 1533 in imitation of the reputed palace of Pilate in Jerusalem; the museum, with masterpieces by Murillo, Zurbaran, Pacheco, Valdés Leal, Herrera, and other artists of the Seville school, as well as by Velasquez (also a native of Seville); the charity hospital, with fine pictures by Murillo and Valdés Leal; the exchange, built by Herrera in 1585, sheltering the valuable archives of the Americas; the university, which was founded in 1254, though the present buildings were erected in 1567; the palace (1697) of the archbishop; the Palace of San Telmo, founded as a naval college by Columbus' son, but now a palace of the Duke of Montpensier; the bull-ring, which can accommodate 18,000 spectators, being exceeded in size by that of Madrid only; and numerous churches.

There is considerable manufacturing industry, especially in the production of cigars (a royal factory employing 4000 work-people), iron, machinery, pottery, cannon, silks, cottons, and various minor commodities. An average of 1295 vessels of 327,650 tons burden enter the port every year, and of this total fully one-third is Spanish and about one-fifth British. The imports, which consist principally of chemicals, timber, textiles, petroleum, machinery, coal, metals, spirits, fish, haberdashery, tinplate, and furniture, average £1,152,900 per annum in value; the first two items make up nearly one-half of the total. The exports, consisting chiefly of lead, quicksilver, wine, copper, oranges, olives and olive-oil, and corks, range from £708,900 (1889) to £1,043,973 (1888). Pop. (1878) 133,938; (1887) 143,182. This city was the Roman *Hispalis*, a place of trade in those days. Here two provincial synods of the church were held, in 590 and 619, and a Spanish council in 782. From 712 to 1248 the city (*Ishbilia*) was an important Moorish town, usually the seat of an emir, in more or less close dependence on the califs of Cordova. When Ferdinand III. of Castile captured it (1248) about 300,000 Moors abandoned the place, and it was a century or two before it began to recover. Its second period of prosperity gradually closed in as Cadiz rose into importance. Seville was the seat of the Spanish government in 1808–10, and suffered severely from Soult's troops in 1810.—The *province* has an area of 5428 sq. m. and a pop. (1887) of 543,944.

Sèvres, a small town of France, dept. Seine-et-Oise, 10½ miles SW. of Paris by rail, is celebrated for its manufacture of artistic porcelain (see POTTERY), an industry carried on under state control since 1756. The Sèvres vases are of great value and are known the world over. Painted glass and mosaic are also made. See the illustrated *Soft Porcelain of Sèvres*, with Historical Introduction by E. Garnier (£8, 8s.; Lond. 1891). The Porcelain Museum contains a large and curious collection of articles in china and earthenware from all parts of the globe. Pop. 7506.

Sèvres, DEUX-, a dept. in the west of France, formed chiefly out of the ancient province of Poitou. Area, 2315 sq. m.; pop. (1886) 353,766. It takes its name from two rivers of the same name, the Sèvre-Niortaise, which flows west into the sea, and the Sèvre-Nantaise, an affluent of the Loire. The northern portion is taken up with the woody plateau of Gâtine. In other parts the soil is fertile, yielding large crops of wheat, oats, barley, potatoes, beet-root, colza seed, wine (nearly 3 million gallons annually), and vegetables. The mules and cattle are celebrated. Coal is mined, and there are good quarries of freestone. The principal industries are in cloth, leather, linen, spirits, flannel, &c., but not to any very great extent except in the first named. The arrondissements are Niort, Bressuire, Melle, and Parthenay. Niort is the capital.

Sewage, the materials conveyed by sewers. A sewer under the existing sanitary acts is a duct or channel used for conveying away the sewage of two or more houses, as distinguished from a drain, which is the duct or channel for the drainage of one house only. *Sewerage* is the term applied to the system of pipes and culverts and their appendages by which sewage is conveyed from populous places. Sewage is composed of the refuse matter other than the dry solids and vegetable debris collected in towns. It consists of the liquid and solid excrements of men and animals; the washings from the streets and slaughter-houses; the waste waters used in cleansing operations; the contents of baths and the organic liquid refuse from some manufactories, together at times with a quantity of rainfall.

In the separate system of sewerage it is assumed that the rainfall, as far as possible, shall be kept separate from the ordinary sewage that is produced in towns and villages. In order to entirely separate rainfall from sewers two systems of drains are requisite for every house, and as a result of the expense the separate system is rarely carried to this extent; but as much rainfall is excluded from the sewers as conveniently can be separated. In recent years it has been the practice, except in very crowded districts, to carry out the separate system, and generally the old sewers and channels, more or less found in all towns, are utilised for conveying away the rainfall falling upon the district, while a new system of sewers is provided for the express purpose of rapidly removing the sewage proper with a portion of the rainfall that cannot be conveniently excluded from the sewers. In streets of great traffic, however, it is found that the liquids flowing from the surface of the roads are as foul as the foulest sewage, and consequently there is no reason why this foul liquid should not be passed directly into the sewers. There are other districts (e.g. Longton) in which there exist connections between the sewers for conveying the rainfall and those for conveying the foul water, with a connection so arranged that the small and impure rainfall should pass into the sewers proper, while the larger rainfalls leap over the opening into the sewer and pass by the surface-water system to some stream in the neighbourhood.

The effect of rain upon sewers even under the separate system requires a very much larger provision to be made for the conveyance of rainfall than for the sewage proper, as the sewers are affected by the rate at which rain falls, and not by the given amount which falls in a day. Under the ordinary rule of thumb calculations the sewers should only admit a quantity not exceeding a quarter of an inch in twenty-four hours, which has been shown to be totally inadequate, and serious flooding has arisen in consequence. Rainfalls in London have been recorded at a rate exceeding 300 cubic feet per acre. On an average of four years' observations made at Croydon it has been found that whenever it rains so as to affect the sewers the rain falls at the rate of 4 cubic feet per acre per minute; and rains have been known to increase the average flow of sewage by over thirteen times its ordinary normal volume. It is therefore important in all systems of sewerage to determine the exact area that shall contribute rainfall to the sewers. In districts of considerable area the rate at which sewers are affected by rain is very much less than in smaller districts of limited area, as in the case of large districts the distant rainfall has to traverse a considerable length of sewer before it arrives at the outfall. The abrupt increase of the flow in the sewer may cause sewer-air to be discharged. But long experience has now firmly established the fact that the water-carriage system of removing sewage is superior on the whole to all other systems.

If the sewers are liable to decay or to leak there is danger of the ground upon which houses are built being fouled; hence comes pollution of the ground-water and the outbreak of various diseases. The bricks used in the construction of all sewer-works should be as impervious as possible, and as a rule no bricks should be allowed to be used in the sewer-work in which the absorptive capacity for water exceeds 12 per cent. of their weight. The materials used in the jointing of brick sewers should also be of the most permanent character, and no other material except Portland cement mortar has yet been discovered which will stand the chemical action of sewage upon it. The smallest sewers are as a rule made of glazed stoneware pipes having various forms of joints. In some, especially wet districts, cast-iron pipes jointed with lead are used to form the sewers. No material should be used in the construction of sewers which will not allow of contraction and expansion by change of temperature. In the case of house-drains the changes of temperature are much more considerable than in the case of sewers, as often in house-drains boiling water may at one period be passing through and at another melted snow. These changes of temperature affect the stability of all sewer-work, and tend to pull it to pieces. The joints therefore should be of such a character if possible as not to present too much resistance, and should be parallel, so that if the pipes move by contraction or expansion the joint will not open more at one point than at another. The ordinary socket joint when properly made is found to be one of the best joints for either sewers or drains.

The size of sewers must depend upon the population, the volume of sewage, and the fall which can be given to them. The average dry-weather volume of sewage in most towns can be taken roughly at 30 gallons per head per day. In some places, however, it is very much less, in others considerably exceeded. The dry-weather sewage is made up by the volume of the water-supply of the district, to which may be added in districts with a wet subsoil a varying amount of leakage into the sewers. There is a daily fluctuation in the flow through sewers. Within a mile of the point of production of the sewage the volume in one hour of maximum flow is at the rate of three times that of the average flow during the whole twenty-four hours, and as a rule one-half the sewage flows away in from six to eight hours per day.

In order to make sewers self-cleansing, either by the natural flow of sewage through them or by artificial means of flushing, they should in the case of small circular sewers or sewers of less than 10 inches diameter never be laid with a less inclination than would give a velocity of 3 feet per second through them; circular sewers above 10 inches diameter and up to 24 inches internal diameter should never be laid at a less slope than would give a velocity of flow of less than 2½ feet per second; and in large sewers the rate of inclination should be such as to give a velocity of not less than 2 feet per second. In house-drains the rate of inclination ought to be such that the flow should not be less than 4 feet per second. This means that a pipe 1 foot in diameter should not have a less inclination than 1 in 160. The proper inclination of any smaller size of pipe or drain to give a velocity of 4 feet per second will be found by multiplying 160, which expresses the proper inclination for a 1-foot sewer, by the diameter of the sewer in feet. For instance, a drain which is 6 inches or ·5 foot in diameter would require to have an inclination of 1 in 80 to give the desired velocity. To give a velocity of 3 feet per second multiply the diameter in feet by 275; thus a 9-inch sewer = ·75 feet should, to give it a velocity of 3 feet per second, have an inclination of 275 × ·75 = 206 or 1 in 206. When the velocity required is 2½ feet per second, then multiply the diameter in feet of the sewer by 386; thus a sewer 2 feet in diameter will require to have an inclination of 386 × 2 = 772 or 1 in 772. When the velocity required is 2 feet per second the number to multiply the diameter of the sewer will be 584. A sewer therefore, 3 feet in diameter, would require to have an inclination of 584 × 3 = 1752 or 1 in 1752, or practically 3 feet per mile fall, to give it the required velocity of 2 feet per second. Where sewers cannot have a proper inclination so as to render them self-cleansing with the ordinary flow of sewage through them, flushing operations are required. These consist either of the sudden admittance of a large volume of water into the sewer, or what is termed sectional flushing, by means of penning back the sewage in sections—i.e. by erecting a dam in the sewer and allowing sewage to accumulate behind it, suddenly removing the dam and allowing it to flush out the lower section of the sewer.

All sewers require to be ventilated. But it is by no means necessary to admit currents of air through sewers for the purpose of ventilation; for it may be taken for granted that the admittance of so much pure air into the sewer at one point of its course means the expulsion of so much foul air at another point. All that is required for the purpose of ventilation of sewers is a series of vents so as to allow the air to escape where it is apt to be compressed by either an increase of flow in the sewers or an increase of temperature; and to allow air to be admitted just as freely when the tendency is for the flow in the sewers to subside and so create air-space.

The simplest and probably one of the best means of ventilating the sewers is by means of pipes carried up to a sufficient altitude above the level of the houses. In no case should any pipe have direct connection with the houses themselves, nor should a rain-water pipe be used for the purpose of ventilation, as these pipes may be blocked by rain when most required for ventilating. Ventilating pipes should be free from all obstruction and interference, and should be independent of other pipes and connections with the sewers. Openings at the levels of the streets have been largely used for ventilators on the score of cheapness, though they are generally a source of complaint at some periods of the year as being a serious nuisance. Sometimes the ventilating gratings of sewers in streets are protected by means of charcoal air-screens, as strongly urged by Dr Stenhouse; and when such screens have been adopted and are so constructed as not to interfere with the free ingress and egress of air from the sewers, they have been found of great advantage, and have immensely reduced the nuisance and probable danger arising from an unprotected street sewer grating.

To secure a sufficiency of fall for the sewers in order to make them self-cleansing it may be necessary to divide a town into a number of sections; smaller sewers with rapid falls convey the sewage with rapidity to a number of different points, and at these points it may be pumped away. This mode of construction has led to the introduction of several methods for the automatic pumping of the sewage, such as the hydraulic system, the vacuum system of Berlier and Liernur, and the compressed air system of Shone.

The *disposal of sewage* is one of the most important points for consideration, as it is no longer admissible for the sewage to be turned in its crude state into the fresh-water rivers and watercourses of the country. Sewage-irrigation has been very largely adopted as a means of purifying the sewage. At one time it was thought that such application would give a reasonable return from the manuring elements which were applied to land; but this has only been realised in a very few instances. Only in cases where it is not absolutely necessary to purify the sewage at all times by its application to the land can it be said to be remunerative, owing to the difficulties which local authorities have in acquiring land for this purpose, and the large sums of money to be paid by way of purchase, often with a considerable contribution for consequential damages arising from some supposed injury to adjoining lands. Nor are the climatic conditions in Britain favourable to the continual application of liquid manures to land. Wherever, however, sewage can be applied or not as required, as in Craigentinny Meadows at Edinburgh, it has been found to produce large and valuable crops of grass well suited for the feeding of cattle. In the case of Croydon, where sewage-irrigation has been carried out more with a view to effect the purification of the sewage, it has been found to have answered every purpose excepting that of making a profit. Here the crude sewage, after having the solids screened from it by means of a revolving screen, actuated by the flow of the sewage, passes on to the land and thence, after its purification, into the river Wandle—a river so small that the flow of sewage forms a very large percentage of the total flow, and yet valuable as a trout stream. The fact that the effluent sewage is passed into it without injury to the fisheries speaks well for the capability of a suitable soil to effect the purification of sewage.

Where Irrigation (q.v.) is adopted for the purpose of purifying sewage, if the land has considerable inclination, the irrigation is usually laid out on the catchwork plan or with contour carriers one above another which shed the sewage on the space below. If the land has a gentle fall, then the sewage is best distributed over it on the pane and gutter system—gutters are cut down in the direction of the fall of the land at distances from half a chain to a chain apart, and from these the sewage is thrown on to the intervening land by means of stops, which are removed from time to time. In the case of very flat land the ground is laid out upon the bed system—i.e. the sewage is brought upon the top of a sloping bed and falls down to a gutter at the bottom of the slope of the bed. In sewage-irrigation works, when purity of effluent is desired, it will be found advisable to so lay out the land as to be able to pick up the effluent sewage which has passed over one area, and to pass it a second, or even a third time, over another plot of land, so as to ensure that no liquid has passed away without being purified.

Another method of purifying sewage is by intermittent filtration through land—i.e. the land is laid out in plots to form a filter, which must be effectually drained, and the sewage, being placed upon a particular plot, is allowed to filter through the land to the drains below. The filtration area is so arranged that the plots are used intermittently or in succession, and in this way a limited area of land may be made to purify a very considerable volume of sewage; the more porous the land, the more sewage it will purify. By this intermittent action a considerable degree of purity is secured in the effluent sewage, and a suitable crop may be grown upon the surface of such filters. Intermittent filtration areas are in common use in connection with most irrigation farms so as to avoid as far as possible the application of the sewage to large areas of land in the winter and at other times when the land is under crop not suited for the application of large volumes of sewage. At the works for the Croydon rural district at Merton, and for the Kingston rural district at Esher in Surrey, the whole of the sewage is treated by intermittent filtration, and these works are typical representatives of this system. In the former case the sewage is applied in its raw state after simple subsidence to remove the solid matters in suspension; and in the latter case the sewage is chemically treated before its application to the land.

It has been found that the purification of sewage, whether by irrigation or intermittent filtration through land, is entirely due to a small organism discovered by Messrs Schlœsing and Muntz in connection with the Paris Sewage Farm. This microbe has the power of converting nitrogenous matter into nitric acid; and investigations made by Professor Warington at the laboratory of Sir John Bennet Lawes and Dr Gilbert at Rothamsted show that it is mostly to be found in surface-soils (see NITRIFICATION). It is not found at any depth below the surface. Messrs Schlœsing and Muntz showed experimentally that if the soil containing the nitrifying organism was chloroformed the organisms were rendered inactive, and in this state sewage could pass through the soil without purification, but nitrification and purification was resumed when the organism woke up. Since this discovery it has been shown that artificial filters may be built of suitable soils and other porous materials which allow the ready admittance of atmospheric air, so that large volumes of sewage may be dealt with upon limited areas. At the works of the Friern Barnet Local Board at New Southgate, the sewage of upwards of 5000 people per acre has from 1885 till 1892 been effectually filtered and purified after chemical treatment by being passed through artificial filters; and during the whole of the time these filters have been in operation they have not had a particle of material removed from their surface. Experience shows, however, that these filters can be put out of order by paralysing the action of the nitrifying organism by giving them an excessive dose of chemicals in the sewage.

Experiments made by the State Board of Health of Massachusetts on intermittent filtration tend to show that coarse sand when used intermittently is capable of purifying 60,000 gallons of sewage per acre per day, and produce an effluent as chemically pure as most drinking-waters. The sewage, however, used in these experiments is much more dilute than sewage in England, as 100 gallons represent the sewage of a single individual per day. Other modes of filtration have been also very successfully used for the purification of sewage—for instance, a sand filter in which there is introduced a layer of mineral substance composed of magnetic oxide of iron combined with carbon, or what is now called polarite, but which was called by Mr Spencer, its discoverer, magnetic carbide of iron. It is now manufactured by carbonising in a retort the materials composing a bed of shale found in the coal-measures of South Wales. This material, like Spencer's magnetic carbide of iron, is shown to have remarkable properties in purifying sewage or other liquids containing organic substances. Filters of this character, however, require constant cleansing, as however perfectly a chemical process may be applied, sewage still contains a certain amount of flocculent matter which tends to clog the surface of the filter-bed. The area of a polarite filter required for the purification of sewage after chemical treatment is comparatively small, as a superficial yard may be trusted to purify in a properly prepared and aerated filter 500 gallons per day.

Chemical Treatment, used either separately or in combination with both natural and artificial filtration, or in connection with some sewage-irrigation works, requires a certain amount of tank space, so arranged as to secure the precipitation of matters separated from the sewage. As a rule, sewage is alkaline, and if it is treated with further alkali in excess, such as with lime, it tends to coagulate certain albuminous substances present; also the lime tends to combine with the carbonic acid contained in the sewage, or held in excess in the waters which go to make up the sewage. The consequence is that a carbonate of lime is precipitated as a flocculent deposit, forming a sort of net, which entangles and drags down other suspended impurities to the bottom of the precipitating tank.

In other cases both an alkaline and an acid chemical are used. It should be noted that there is hardly an earthy salt that has not been used in connection with the processes of precipitating sewage; the salts of alumina, iron, lime, magnesia, potash, soda, silica, zinc have all been used, either by themselves or in combination with each other. When an alkali and an acid salt are used for precipitating sewage, such as lime and sulphate of alumina, the lime should be first added as a milk of lime to the alkaline sewage, which tends to increase its alkalinity. The sulphate of alumina dissolved in water or sewage is subsequently added, and the alumina itself is precipitated as an insoluble hydrated oxide of alumina, which drags down impurities with it; while the lime combines with the sulphuric acid of the sulphate of alumina and forms a sulphate of lime, which goes away as solution in the effluent, so that the total solids in solution in the effluent are in excess of those in the sewage. Of all the precipitating processes the lime process is the only one in which there is less solid matter in solution in the effluent than in the original sewage, and, combining cheapness with efficiency, more work is got out of it for a given expenditure than by any other process. Lime effluents, however, unless passed over or through land or artificial filters, are as destructive to fish life as decomposing sewage, and therefore should not be turned direct into any stream in which injury is likely to arise to the fisheries.

Sewage Sludge is the semi-liquid substance that is deposited in tanks, whether by mere sedimentation in preparing the sewage for its application to land, or by its chemical treatment and clarification; and the disposal of this sludge is often a difficult problem. If not already in a state of decomposition, it is very likely soon to be highly offensive from that cause, and if exposed in an inhabited neighbourhood would soon prove to be an intolerable nuisance. Sludge is a difficult material to handle, as when it leaves the tanks not less than 90 per cent. of it is water. In some instances it is pumped direct on to land and at once covered over with soil; in others it is left on the surface of the land, not without risk of nuisance, until a large part of its moisture has either evaporated or filtered into the ground, when it is dug in. In some cases the sludge is mixed with other refuse of towns, and burned in destructors. In one case it is taken by steam hopper barges out to sea and cast away, as being the least expensive method of its disposal. By far the most effectual way of disposing of the sludge is to pump it into filter-presses. In this way it is rendered portable, and becomes free from nuisance, as sufficient water does not remain in the mass to render it offensive and liable to decomposition, and what does remain is soon partly evaporated. By pressing, about five and a half tons of crude sewage direct from the tanks are reduced to one ton of pressed sludge, containing about 50 per cent. of moisture. Pressed sludge is just about as valuable as farm-yard manure, and its sale in some places realises something, and partly defrays the cost of pressing.

London sewage is discharged by two outfalls—viz. Barking on the north and Crossness on the south, into the river Thames, which divides the metropolis into two distinct drainage areas. The sewage on the north side is chemically treated and sludge removed before the clarified effluent is discharged into the Thames. On the south side of the Thames similar sewage-works were about to be constructed in 1892. On the north side of the Thames there is a population of about 2,900,000, and the dry-weather flow of the sewage is roughly estimated at about 100,000,000 gallons per day. The sewage first receives lime in the form of lime-water at the rate of 3·7 grains of lime per gallon of sewage, and subsequently lime-sulphate at the rate of 1 grain per gallon of sewage. In hot weather, however, the sewage receives further treatment, and a small quantity of permanganate of soda is applied to the sewage, usually about 1000 tons of permanganate being used in the course of a season. The sludge produced at the existing sewage-works at Barking, on the north side of the Thames, is about 21,000 tons per week, of which 91 per cent. is water. After getting rid of a portion of the water, the remainder is pumped into steam hopper ships specially constructed, and is conveyed down the Thames and out to sea, where it is discharged, this mode of disposal being found the cheapest method.

For many years the sewerage systems of American cities were modelled on European methods; but experience showed that the conditions on which these were based—as to rainfall, for instance—differed so much from those of America, that of late the special needs of each particular case have been more carefully studied. Chicago, Memphis, and various summer-resorts may be mentioned as cases where local conditions have largely modified the methods of sewerage employed.

House-drainage.—However perfectly the sewers of a town may be constructed, however safely the sewage may be disposed of, yet if care has not been taken in the design and construction of the works necessary for the drainage of each individual house very little sanitary benefit may accrue. And in any case direct evils are almost certain to follow bad house-drainage work. All house-drains, while rapidly carrying away from the house all liquid refuse, fæcal, and other matters, must be so constructed as to preserve the site of the habitation from being polluted and prevent the entrance of any sewage-air into the house. As a rule it is now required that every house-drain connected with a public sewer shall have an intercepting trap placed between the house and the sewer. This trap serves the purpose of cutting off the direct connection between the house and the sewer, so that if the house-drainage works are imperfectly carried out the intercepting trap will at least prevent the air of the public sewer entering the house. The intercepting trap also forms an opening at the lower end of the house-drain by which air can enter the drain. All house-drains require to have separate and independent ventilation by means of either the soil-pipe or some special pipe at the head of the drain, and its branches carried up to a point somewhere near the top of the house; but it must not terminate near the eaves or a window or the top of a chimney, for at all these points at certain periods there are direct air-currents into the house which would carry the foul air from the ventilating pipe into the habitation.

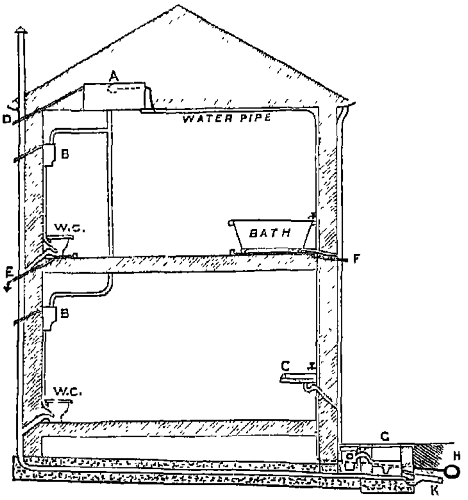

Fig. 1.

The apartment for the water-closet in a private house should be well lighted and ventilated. A window should always be provided, which should open to the external air, and should be carried up to near the ceiling of the apartment. It is also desirable that air-bricks should be built into the external walls, both at a level with the floor and near the ceiling. In large dwellings, and public buildings, such as hospitals, workhouses, and hotels, it is desirable that the water-closets should be separated from the main building, and be approached by a corridor with doors at either end, and having through ventilation, so as to cut off the direct communication of the closets from the rest of the building. Such an arrangement will, in a severe winter climate, need special provision for heating the apartments.

Fig. 1 gives an illustration of a section of a house constructed in accordance with the sanitary requirements of the Model Bylaws of the Local Government Board. Fig. 2 shows the arrangement adopted in the case of houses in streets, showing the position of the intercepting trap and air opening at the kerb of the street. With reference to the sinks and baths of houses, the simplest way of dealing with these appliances is to allow the pipes to pass through the external wall, and to discharge on the top of a trapped gulley outside the building, as shown in fig. 3.

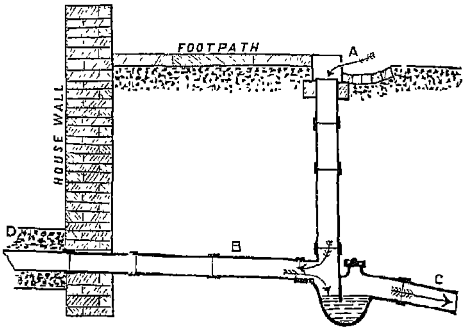

Fig. 2.
A, air-inlet in kerb; B, 4-inch drain; C, to sewer; D, concrete.

The old pan closet, the invention of Bramah, is a most intolerable nuisance and source of danger if admitted into a house. This form of closet has been so generally recommended by plumbers and others whose interest it has been to foist it upon the public that a description of it is desirable. It consists of a moving pan at the bottom of a basin, which is worked from the handle of the closet, and a receiver, against the sides of which the contents of the pan are projected every time the handle of the closet is raised, the consequence being that the walls of the receiver get plastered over with fæcal matter, which, decomposing, generates noisome gases. These gases being confined in the space between the water seals of the pan and that of the D-trap at the bottom, when the closet is used and the contents of the pan are discharged into the

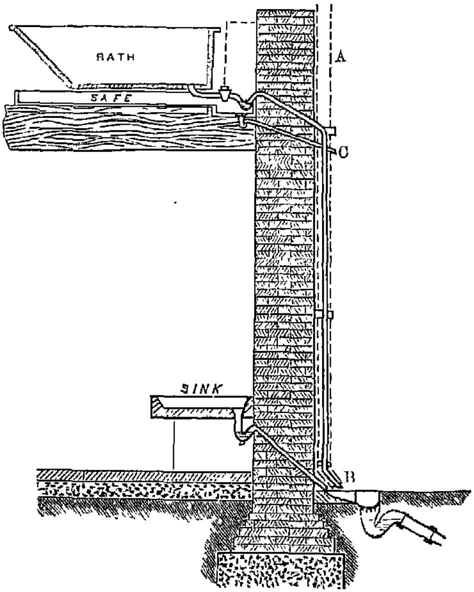

Fig. 3.
A, rain-water pipe disconnected below; B, bath and sink waste-pipes disconnected; C, overflow from safe under bath.

receiver, a portion of the noisome gas escapes at once into the atmosphere of the apartment in which the closet is located, and very often pervades the air of the habitation. This is a form of water-closet that never should, under any circumstances, be used, and, as it is expensive both in first cost and in maintenance, it is difficult to understand how it is that it still finds a place in the houses of the people. The D-trap which is used in connection with this pan closet should also be prohibited.

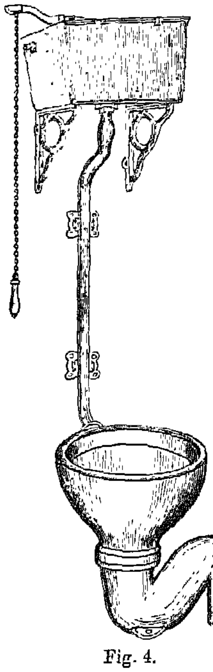

Fig. 4.

The valve water-closet is also largely used. It has a valve at the bottom of the basin, and it differs but slightly in principle from the pan closet. In this form of closet there is not so much space between the valve and the trap as in the pan closet. It is, however, difficult to maintain the valves water-tight, and, on the other hand, it is an expensive article, and nothing like so perfect a sanitary appliance as some cheaper forms of closet.

The ordinary hopper closet is one of the simplest, cheapest, and most sanitary devices, and when furnished with an adequate flushing-cistern is one of the best and sweetest appliances which can be used in houses. This is shown in fig. 4. The flush-out closet (fig. 5) is a closet which has been largely used in recent years. It has some objections in consequence of the fæcal matters being spread out over a large area and but imperfectly covered with water, and the tendency of the flush water to break up the fæcal matters deposited in the basin, which gives rise to effluvia when the closet is used.

Trough closets are largely used where numbers of people congregate together, as in clusters of cottages, workhouses, mills, and barracks. An ordinary form of closet or latrine is shown in fig. 6. This is cleansed by a flushing-tank which fills up slowly with water, and discharges rapidly by siphon action. The provision of urinals, lavatories, and water-closets for public use is a matter of necessity in most towns, and lately in large towns these conveniences have been constructed in chambers below the street level, which are approached by a flight of steps.

In the case of detached houses and cottages where there are no sewers it is often a difficult matter to know how to deal with the liquid refuse produced, including the chamber slops and waste water. Probably, in the majority of cases, the best mode of dealing with these matters is by application to the garden by throwing them on the surface, or into an open trench freshly cut for the purpose, and as far from the habitation as possible. Means have also been provided in some rural districts to distribute these waters by a series of underground agricultural drain-pipes laid about 1 foot below the surface, and intermittently charged by a gulley having an intermittent discharge by means of a siphon connection with the drain. Where waters are distributed in this way in retentive soils a lower set of agricultural drains laid at a depth of about 4 feet should be provided for collecting the drainage after purification in passing through the land. The success of this mode of disposal, however, largely depends upon the nature of the ground.

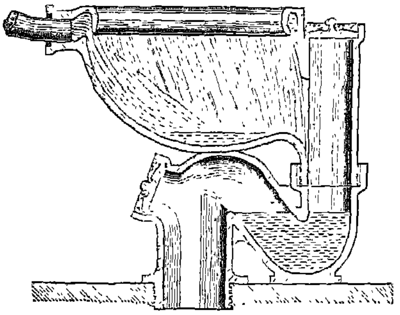

Fig. 5.

Cesspools.—Wherever it is necessary to construct a cesspool for the retention of sewage, it should be in such a position with reference to the water-supply as not to foul (in case the cesspool leaks) any well used as a source of water-supply. As all underground waters move in particular directions, the cesspool should invariably be on the lower side of the source of water-supply. It is absolutely necessary that cesspools should be built of good materials, and made perfectly water-tight with Portland cement, otherwise pollution of the ground and ground water is sure to arise, the evil consequences of which may spread for unlimited distances in the direction of the moving ground water. Cesspools also require to be properly ventilated,

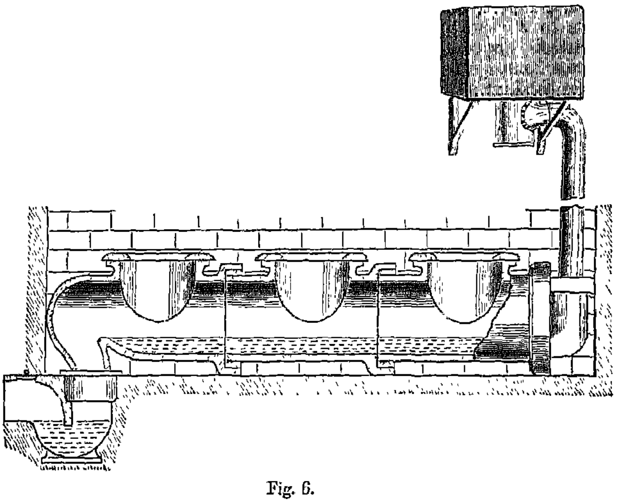

Fig. 6.

and they should be so located that in emptying them it should not be necessary to carry their contents through any dwelling-house or building in which persons are employed.

In some towns and districts there seems to have been a great prejudice about admitting the fæcal matters of the population into the sewers, and in such districts various forms of dry conservancy have been adopted. The Middenstead appliance is one in which the fæcal matters of the population are mixed more or less imperfectly with ashes and garbage. Formerly these middensteads had the adjoining ashpit uncovered, and still in many places they remain uncovered. A great improvement was effected when it was made a necessity that the ashpit should be roofed over to prevent the rain percolating into the vault below. A still greater improvement has been attained by insisting that the floor of the chamber should be located above the level of the surface of the ground; that the ashes should be properly distributed over the fæcal matter; and that the space should not be greater than to hold the contents of one week's supply, or about 8 cubic feet in capacity. An *illustration of this is shown in fig. 7; A represents* the plan of a pair of closets of this description, and B a section of the closet. In no case ought a privy to be under the roof of the dwelling-house, and the least distance it should be from an inhabited building is 6 feet. It has been clearly shown that in some large towns in which this middenstead system is very largely adopted it leads to a very high death-rate amongst the inhabitants, especially amongst the children, and cannot compare for health or cheapness with the water-carriage system.

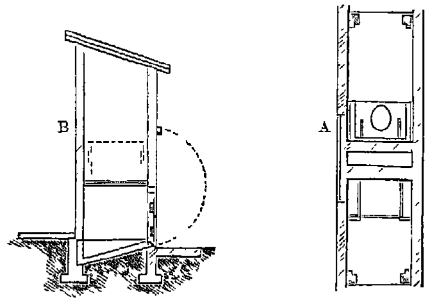

Fig. 7.

The Pail system has also been largely adopted in some towns for receiving the fæcal matter only of the population. The pail is usually placed below the closet seat. Where the pail system is in use the whole of the interior surrounding the pail should be flagged, asphalted, or cemented. The floor of the chamber should be kept above the ground level, and the contents of the receptacle should not exceed 2 cubic feet, and it should be removed at least once a week. An arrangement by which the sifted dust from the ashes is passed into the pail, so as partially to effect its deodorisation, is also very useful in detached houses. All these appliances of dry conservancy, however, only deal with part of the polluting matter produced by the population; the rest finds its way to the sewers, and the sewage is found to be none the less offensive because a part of the fæcal matter has been kept out of the sewers. And the collection and manufacture into manure of all the matters that are collected in towns has only resulted in a dead loss to the authorities of every town that continues to maintain these systems.

The Earth-closet system is the invention of the Rev. Henry Moule, vicar of Fordington, Dorset. It consists of the application of earth to the deodorisation of fæcal matters, and is a valuable system in its proper place; but it cannot compare in efficiency with the water-carriage system in a town in which there are sewers. In detached houses, however, and country places, and in some public buildings it has proved to be an exceedingly valuable adjunct to other sanitary appliances. The first requirement for the successful working of the earth system is that earth of a loamy character, *perfectly dry and finely sifted, should be used.*

Earth closets are of two varieties, those with fixed receptacles and those with movable receptacles. For the interior of the house the latter only should be used. In earth-closets outside the dwelling the materials may be allowed to accumulate in a dry vault for three months without any injury or annoyance, provided sufficient suitable dry earth was originally used in the closet. It is found that fæcal matter when mixed with sufficient dry earth is completely disintegrated, and together with paper entirely disappears in the course of a few days, and that no decomposition takes place during the process. In the case of closets with movable receptacles they should be emptied every week. Apparatus for supplying the earth should be fitted and form part of the closet, and should be made self-acting. No slops should be thrown into an earth-closet.

The quantity of dry earth required in England for use in the earth-closet is about 2½ lb. per head per day, which is about five times the weight of the fæcal matter that is collected in those towns in which the pail system is in operation; so that the volume of earth required is large in proportion to the matter dealt with; and it is difficult to procure and expensive to carry in the case of a large population. Of course the earth after removal is from an agricultural point of view more valuable than before use, but, unfortunately, it does not produce a manure of a high class. The earth in an outside earth-closet may be used several times over, provided it is dried each time before use; and this adds to the value of the manure and reduces the cost of earth. Fig. 8 represents a form of earth-closet

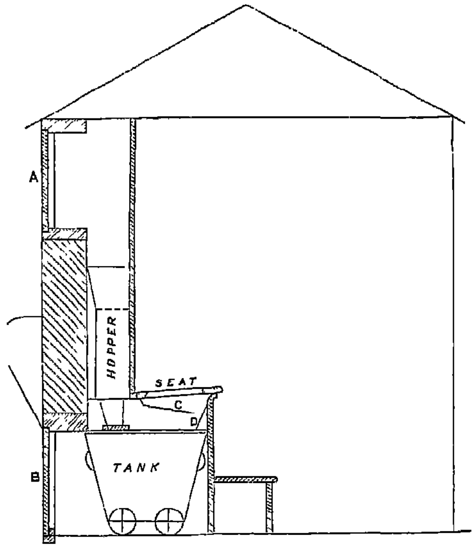

Fig. 8.
A, door-opening for filling hopper, B, door for emptying tank; C, shield; D, slide.

which is actuated from the movement of the seat of the closet, and in which the earth after admixture with the fæcal matter is retained in a tank on wheels which can readily be removed and replaced with another tank when required. The objection to the earth-closet is that it necessitates heavy double carriage of the materials, and that it only deals with part of the refuse produced. From a sanitary point of view, however, it is clearly superior to any other method of dry conservancy.

Pneumatic Systems of Sewerage.—The Liernur system, the oldest pneumatic system of sewerage, is the invention of Captain C. T. Liernur, and is in operation in some continental towns, especially in Holland; but there is no town at present in which the entire sewage of the whole town is treated on this system. The Liernur system consists in aiding the withdrawal of the fæcal matters from the habitation with the assistance of air-pressure. Under this system, at some convenient central place, works are erected, and steam or other power is provided which gives motion to an air-pump which keeps certain air-tight receivers exhausted or partially exhausted of air, and these receivers communicate by means of air-tight iron pipes with various convenient stations throughout the district that is to be served by this system. From these latter stations other iron pipes branch off into the streets, and with these pipes the individual houses are connected by means of iron pipes with a valve on each house-drain, which is controlled from outside the house by the persons in charge of the system. The closet within the house is a truncated conical vessel with a bent pipe at the bottom, looking like a trap, but which is used for receiving and storing the fæcal and other matters deposited in the closet. A partial vacuum being maintained in the pipes of the system, it is obvious that if the valve at the street front of the houses is suddenly opened the atmospheric pressure acting on the matters collected in the bent tube at the bottom of the closet and in the pipes between this point and the valve will be withdrawn and a large volume of air will be carried into the pipes, which will continue so long as the valve is open and a partial vacuum is maintained. The Liernur system, from a sanitary point of view, is little better than the pail system; and, in spite of the value put on the manure, it is, when compared with a proper system of sewers and water-carriage, very expensive. All the pipes and fittings must be constructed of iron, and it does not deal with the whole of the sewage, so that a system of sewers is requisite for dealing with the greater part of the waste waters. In all the pneumatic systems the large volume of foul air exhausted from foul pipes, and again liberated into the atmosphere, is a source of very considerable danger to health.

The Berlier system, which has been partially adopted in Paris, is similar to the Liernur system, except that the discharge from the house into the vacuum-pipes in the street is automatic in its action. The same objections apply to this as to the Liernur system.

The Shone system is another pneumatic system, used simply for raising sewage from one level to another higher level. In this system, instead of a vacuum being used, air above atmospheric pressure is directly applied to the liquid sewage contained in an iron vessel called an ejector, and the direct pressure of the air forces the sewage out of the ejector to the required altitude. Under this system the town is usually drained on the separate system of water-carriage to a number of convenient points at which there are ejectors. The air used for transmitting the requisite power is compressed at some convenient point, and is distributed through iron pipes to the various ejector stations to be used as required. The Shone system is ingenious, but very expensive, both in first cost and to maintain at work, and it has the sanitary disadvantages, in common with other pneumatic systems, of liberating foul air into the atmosphere. It has, however, been adopted by the authorities of several small English towns, and is in operation at the Houses of Parliament.

The Hydraulic Sewage System.—This is a system that has for its object the local pumping of sewage at several points within a district, and raising it to a higher level. In this case the district may be divided into a number of separate areas, and at some convenient central position in each area an automatic hydraulic pumping-station is established, to which the sewers of the district gravitate. In this system a power-station is provided just as in the various pneumatic systems, and at this station steam or other power is employed, this power being transmitted throughout the district to the various automatic stations by water at high pressure. At the power-station the water is pumped into an accumulator, which is a cylinder weighted to the requisite pressure, riding on a ram, through the centre of which the water enters the cylinder, and the cylinder rises and falls as it is more or less filled with water. From this accumulator pipes are carried to the various automatic pumping-stations throughout the district. The automatic hydraulic engines at the various local stations are simply direct-acting pumping-engines, in which the high-pressure water gives motion to a piston within a cylinder, and this in turn works a pump directly attached to it. The automatic engines are controlled by a float in such a way that when there is sewage to pump it is pumped just as fast as it flows from the sewers, and when the flow of the sewage declines the hydraulic engine stops until the supply of sewage is replenished. In the transmission of the power, water under a pressure of 700 lb. per square inch or more is used; and the great advantage of the system over any pneumatic system arises from the fact that a large amount of power can be distributed with little loss. For the friction of water, unlike air, in passing through pipes does not increase with the pressure; there is just as much loss in transmitting water at 10 lb. pressure per square inch as at 1000 lb. per square inch through a pipe of the same size, and consequently the actual percentage of loss at the higher pressure is very small. Another great advantage of water over air is that there may be any number of variable altitudes to which the sewage is raised without loss of power, as it is only a question of grading the size of the cylinders of the automatic hydraulic engines to adapt them to any lift. High-pressure water can also be stored in an accumulator ready for urgent work without increase of pressure, and without the loss that arises when it is attempted to store air in a receiver for use. Again, the water that has been used for transmitting the power is used for the purpose of flushing the sewers, as it may be distributed to automatic flush-tanks. This saves the cost of buying water for the purpose of flushing the sewers; generally the water so applied, if it had to be purchased, would involve a greater expenditure than the whole cost of transmission of the power. The water used for transmitting power may be the purified sewage or subsoil water, and if the latter source is adopted the result of taking it from the ground and so reducing the water-level is a further great gain from a sanitary point of view.

The hydraulic system of pumping is more economical at work than any other system, and it occupies less space than any other apparatus.

Two engines of this kind, capable of raising together 1½ million gallon per day, can be accommodated in a chamber of 9 feet in diameter, which can be constructed wholly below a public road; and its existence would be unsuspected, as the engines are noiseless in their action and require very little attention. The system has already been adopted and is at work in the districts of Friern Barnet, Esher, Thames Ditton, Long Ditton, and Margate, and is being adopted by the authorities of other towns both in Britain and in other countries.

The Electrical System of Sewerage.—This system, sooner or later, is likely to come into operation in towns, for the purpose of automatically pumping the sewage. It has already been successfully used in pumping water in mines, and it has been shown to give more than double the duty that can ordinarily be secured by the use of air under pressure; so that there is no reason why, in towns in which electric lighting has been employed, the same apparatus may not be used to transmit power for the purposes of the automatic pumping of the sewage. For an electric or other plant is only really economical when it works continuously up to nearly its full power; and as sewage pumping is most required in the daytime and electric lighting at night, by combining the two this would be effected and a certain economy would result. Electricity has already been applied experimentally to the purification of sewage, combining a chemical precipitating process with oxidising properties that have been shown to purify sewage.

Also the article HYGIENE.

Seward, ANNA, the 'Swan of Lichfield,' was born in 1747 at the rectory of Eyam in Derbyshire, but lived from the age of seven all her days at Lichfield, where her father, himself a poet, became a canon residentiary. Dr Darwin and Mr Day were notable figures in the society of Lichfield; her dearest friend was Honora Sneyd, who married Edgeworth; Dr Johnson, like the prophet of the proverb, had more honour everywhere else than among his own people. Miss Seward only escaped a nearer connection with the lexicographer by the death of her only surviving sister Sarah on the eve of marriage with Lucy Porter's brother. Her own father died in 1790, but she continued to live as before in the bishop's palace, dear to her friends and correspondents—Mrs Piozzi, Hayley, Southey, Scott—and died 23d March 1809. She published her poetical novel, *Louisa*, in 1782; her *Sonnets* in 1799; her Life of Dr Darwin in 1804; but bequeathed to [Sir] Walter Scott the care of the collected edition of her poems (3 vols. 1810). Her long-winded, florid letters, on which she piqued herself even more than her poems, were collected in six volumes (1811-13). Boswell received from her 'some obliging communications concerning Johnson,' but after his book was published quarrelled with her, accusing her of malevolence towards his hero. Her monody on Major André and an elegy on Captain Cook were thought her best poems. In the letters she is Johnsonian without strength, metaphorical beyond all measure, feeble and absurd to a degree. Horace Walpole says of her and some other harmonious virgins, 'Their thoughts and phrases are like their gowns—old remnants cut and turned.'

Seward, WILLIAM HENRY, an American statesman, was born at Florida, Orange county, New York, May 16, 1801, graduated at Union College in 1820, was admitted to the bar at Utica in 1822, and thenceforth made his home at Auburn. He early took an active interest in politics, and in 1827 presided over a young men's convention held at Utica to advocate the re-election of John Quincy Adams to the presidency. In 1830 he was elected, as an anti-Mason, to the state senate, where he remained four years, leading the opposition to the dominant Democratic party. In 1834 he was the unsuccessful Whig candidate for the governorship of the state of New York, but was elected to that position in 1838, and again in 1840. A noteworthy incident of his administration was a controversy with the governor of Virginia in regard to three negro seamen, whom the latter claimed as fugitives from justice, on the charge of inciting a slave to escape, and whom Governor Seward refused to surrender. Having declined a third nomination, he was engaged from 1843 to 1849 in the practice of his profession, being especially sought after in criminal and patent cases. In 1847 he defended John van Zandt, accused of aiding in the escape of fugitive slaves, and incurred obloquy by his defence of the negro murderer, Freeman, on the plea of insanity. His argument in this case was pronounced by Mr Gladstone 'the greatest forensic effort in the English language.' Mr Seward continued to give active support to his party, while at the same time making himself remarked as an opponent of the pro-slavery policy. In a speech against the admission of Texas into the Union he said: 'To maintain the slave-holding power is to subvert the constitution;' and at Cleveland, during the campaign of 1848, he told his hearers, in speaking of slavery: 'It must be abolished, and you and I must do it.' In February 1849 he was elected to the United States senate, where he served two full terms, being re-elected in 1855. He was much consulted by President Taylor, but declined to be put on any important committee lest his opinions on slavery should embarrass the administration. In 1850, while urging the admission of California into the Union, he declared that the national domain was devoted to liberty, not only by the constitution, but by 'a higher law than the constitution'—a phrase which became famous. He opposed the Compromise Bill of 1850; separated himself from those Whigs who followed President Fillmore in his pro-slavery policy; opposed the Know-Nothing (q.v.) party; and on the formation of the Republican party became one of its leaders. His speeches in the senate on the repeal of the Missouri Compromise and the admission of Kansas made a great impression, as did also an address delivered at Rochester in 1858, in which he spoke of the 'irrepressible conflict' between freedom and slavery.

Copyright 1892 in U S. by J B Lippincott Company.

In 1860 Mr Seward was a candidate for the presidential nomination, but on failing to receive it gave his hearty support to Mr Lincoln, whose cabinet he entered as Secretary of State, an office which he held through two administrations, from 1861 to 1869. The civil war, which was in progress during the first half of this period, rendered the foreign relations of the United States unusually delicate, especially in view of the attitude of the governments of France and Britain. In the 'Trent' affair he was obliged, in opposition to popular clamour, to admit the justice of England's claim and to advise the president that the Confederate envoys should be given up. He protested against the fitting out of the *Alabama* and similar vessels in British ports, and declared that the United States would claim from the English government indemnities for damages resulting from this breach of the obligations of a neutral power. On the subject of the French invasion of Mexico he maintained a prudent reserve, until the conclusion of the war enabled him to insist on the withdrawal of the French troops. On April 14, 1865, while confined to his bed with a broken arm and jaw, the results of a carriage accident, he was attacked and severely cut on the face and neck by an accomplice of J. B. Booth. He supported President Johnson's reconstruction policy, thereby placing himself in opposition to the majority of his own party and incurring much bitter censure. In 1867 he negotiated with Russia the treaty for the purchase of Alaska. After leaving office he travelled in 1869 to California and Alaska, returning through Mexico, where he was warmly welcomed as the guest of the nation; and in 1870-71 he made a tour round the world, his narrative of which was edited and published (1873) after his death by his adopted daughter, Olive Risley Seward. He died at Auburn, October 10, 1872. Without being a creative statesman, Mr Seward had great practical ability controlled by sound notions of truth and justice; always a party man, he was never an extreme partisan, and rather made public opinion than followed it. Strong convictions joined to a conciliatory disposition rendered him a fitting representative of the moderate anti-slavery sentiment and a worthy fellow-worker with Lincoln in preserving the Union.

See his Autobiography, continued to 1846 in a memoir by his son (1877), and to 1872 in his *Life and Letters*, by the same (2 vols. 1891); the Life by T. K. Lothrop (1891); also Charles F. Adams' Address on his Life, &c. (1873), and the memoir by George E. Baker published with his *Works* (3 vols. 1853; 2 other vols. 1862-84).

Sewell, Elizabeth Missing, author of a long series of High Church novels, the daughter of a Newport solicitor, was born in the Isle of Wight in 1815. Her first novel, *Amy Herbert*, was anonymous, and edited like three or four more of her early works by her brother, the Rev. William Sewell, vicar of Yaxley. She has produced more than forty volumes, including novels and devotional works. There is an edition of her works in 11 vols. (1886). She has been a frequent contributor to the *Monthly Packet*.

Sewellel. See Haplodon.

Sewing-machine, a machine for sewing and stitching upon cloth, leather, and other fabrics. It is one of the most important labour-saving inventions of the age, and is extensively used for domestic and manufacturing purposes throughout the civilised world. By its use the labour of doing the family sewing has been reduced to a minimum, a new and profitable article of merchandise, to wit, 'ready-made clothing,' created, the manufacture of shoes and various articles of merchandise greatly facilitated, and the processes of their manufacture revolutionised.

Copyright 1892 in U.S. by J. B. Lippincott Company.

There are at the present time a large variety of sewing-machines manufactured, each adapted to the kind of work it is intended to perform, as the Family Sewing-machine, for general domestic or family purposes; the Manufacturing Machine, for manufacturing purposes; the Cylinder Machine, for the vamping of shoes, stitching of water-hose, water-buckets, mail and travelling bags and satchels, and generally for leather-work; the 'Universal Arm Feeder Machine,' used largely in the manufacture of gloves and repairing of shoes; the Over-seaming Machine; the Carpet Sewing-machine; the Jacquard Pattern-stitching Machine; the Stay-stitch Machine; the Basting and Quilting Machine; the Button Sewing-machine; and the Button-hole Machine. Indeed the sewing-machine, in the present stage of development, is adapted to all kinds of plain or fancy sewing required, whether it be upon the finest tulle or gossamer, or the heaviest shoe, harness, or upholstery work, and for the purposes of its construction furnishes a striking illustration of the possible accuracy, adaptability, and perfection of machinery.

The familiar family sewing-machine, as made by Wheeler & Wilson, is worked with the foot by a treadle motion, and, with its various attachments of 'hemmers,' 'fellers,' 'corders,' 'binders,' 'quilting-gauge,' &c., is adapted to all kinds of family sewing. The same machine, without the stand, is fitted up with a crank, to be operated by the hand. Sewing-machines are also run by the spring or electric motor for home use, or by steam-power in factories. Sewing machines may be divided into classes, according to the stitch made, as the 'chain-stitch,' the 'double-loop stitch,' the 'lock-stitch,' and the 'button-hole stitch' machines.

The 'chain-stitch' machine uses but one thread, looped upon itself, by means of a curved needle or hook, beneath the cloth, which catches the thread as it is carried through the cloth in the eye of the vertical needle, and holds it until the second descent of the needle, this time through the loop thus made, which is drawn up upon the under side of the cloth as the vertical needle again rises, and so on—thus making a chain of stitches which is easily unravelled. Machines of this class are of limited application, being better adapted for embroidering and basting than for manufacturing purposes or for general domestic use. Fig. 1. represents this stitch. The Wilcox & Gibbs is an illustration of this class of machine.

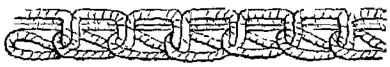

Fig. 1.

The 'double-loop stitch' is a machine using two threads, one upon each side of the fabric—the upper thread in the eye of the vertical needle above the cloth, the other in the circular needle which vibrates immediately beneath the cloth. By the descent of the vertical needle the upper thread is carried down through the cloth, where it becomes looped and interlooped with the under thread, forming a stitch which, being interlooped with the adjacent stitch, presents the appearance of three threads interlooped upon the under side of the cloth, and upon the upper side the single thread as in the 'single chain-stitch.' This 'Grover and Baker stitch' makes a strong and durable seam, but consumes a large quantity of thread, and is easily unravelled. The Grover & Baker machine, upon which this stitch was originally made, is no longer manufactured; the 'stitch' has, however, been retained in some of the more modern machines.

The 'lock-stitch' class of machines, sometimes called the 'double lock-stitch' machines, comprises fully four-fifths of all the machines now in use, and is admirably adapted for domestic and manufacturing purposes. Like the 'double-loop stitch' the 'lock-stitch' machine is a double-threaded machine, having one thread upon either side of the fabric.

The upper thread of the lock-stitch machine, passing from the spool as it is purchased and placed upon the 'spindle' or 'spool-holder' upon the arm of the machine, through the 'thread-check,' around the 'tension-pulley' or between the 'tension-discs,' through the 'thread-guide,' 'take-up,' and 'leader' (these are of various devices), finally through the eye of the vertical needle, is carried by the descent of the needle bar downward through the cloth and the loop of the under thread, and by the upward motion of the needle is again brought back through the cloth, drawing the under thread upward to the centre of the fabric, where, by a proper adjustment of the tension of the two threads, they are locked, making a perfect stitch, exactly the same upon both sides of the cloth. Fig. 2 represents the 'lock-stitch,' than which nothing better is required for sewing. By this stitch an elastic and durable seam is made, which even the skilled operator finds difficulty in ripping. It will not unravel. Of this class of machines there is also a large variety, which may be subdivided into two classes—those using the vibratory, oscillatory, or shuttle motions, and those constructed entirely upon the rotary motion principle.

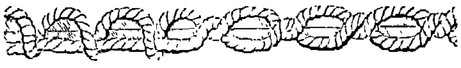

Fig. 2.

The Singer and Wheeler & Wilson are the leading exponents of these two classes of lock-stitch machines, and are the two great competitors in the markets of the world. There are many other excellent lock-stitch machines whose names are familiar both in homes and workshops, as the Howe, Remington, Florence, Weed, Domestic, American, &c., the latter using a rotating shuttle, all of which make the lock-stitch in the centre of the fabric, and are constructed either upon the principle of the vibratory or oscillatory shuttle motion or upon that of the rotary motion.

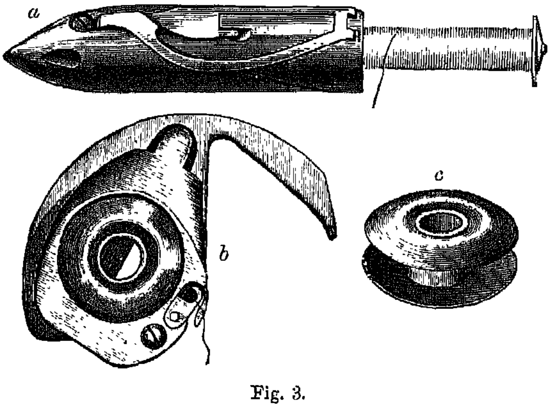

Fig. 3.
a, vibrating shuttle; b, oscillating shuttle; c, bobbin of oscillating shuttle.

Fig. 3, a, represents the vibrating or reciprocating shuttle of the Singer machine. All of the Singer machines were originally constructed with this mechanical device for the supply of the under thread, the shuttle vibrating beneath the 'baster-plate.' The oscillating shuttle was adopted by the Singer Manufacturing Company in 1878. The loop is formed and caught by the beak of the shuttle as in the reciprocating shuttle. The shuttle has a long beak, the object of which is to hold the loop until the needle has been lifted entirely out of the goods. While the needle is out of the goods the loop is opened by the body of the shuttle sufficiently to pass through, the thread being pulled down through the needle's eye and the opening through the goods left free for the thread to play in, a vast friction and strain upon the thread being thus avoided. Fig. 4 represents the sewing device of the Wheeler & Wilson family machine, consisting of a rotating hook, formed by a disc of polished steel, with 'slot' cut in its periphery and its pointed ends curved, which being attached to the horizontal pulley shaft revolves with it, giving off from its bevelled edge at each revolution a loop of thread, formed by the upper thread on the outer side of the needle as it descends through the 'slot.' This loop is caught upon the rotating hook and carried along with it about two-thirds of the way round, and, as it slips off and the thread is again partially drawn up by the rising needle, crosses the bobbin, catching its thread and drawing it upward, thus forming interlocking loops, which tightly drawn form the stitch. The bobbin is perfectly free, is neither pivoted nor placed upon an axle, but is fitted in a concave holder upon the outer side of the rotating hook and revolves in the opposite direction from the hook, thus securing a proper tension and giving off at each revolution sufficient thread for one stitch. Fig. 5 represents the sewing mechanism of the manufacturing machine of this make—'No. 12'—constructed with a view of securing the highest speed, accuracy, and economy of power consistent with the rotary motion. The bobbin is placed upon a 'stud' or 'axle' in the centre of the rotating hook, and the thread is drawn through a 'slot' in the periphery of the bobbin-case, and held securely by a spring or passed through an eyelet.

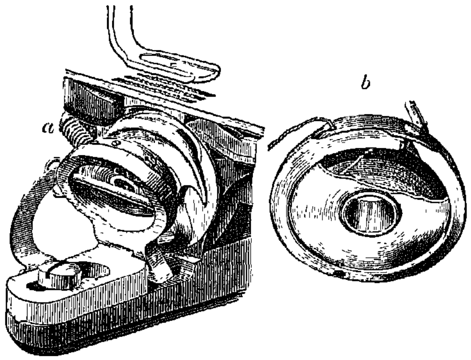

Fig. 4.
a, rotating hook, bobbin-holder with bobbin, &c.; b, bobbin and bobbin-case.

This machine is also constructed with a 'cylinder feed' especially adapted to the vamping of shoes (the vamp being stitched just as it comes from the pasting block), which is easily changed into a 'flat-bed' machine by means of an adjustable platform, adjusted over the cylinder feed; and, as represented in fig. 6, it may be constructed as a three-threaded machine, having two parallel threads which by its peculiar mechanism become interlocked alternately with the under thread, forming a zigzag stitch upon the under side and presenting two parallel rows of stitching upon the upper surface, each row having the exact appearance of the ordinary lock-stitch. The stitching thus made can be taken out only stitch by stitch, and is largely used upon the 'uppers' of shoes.

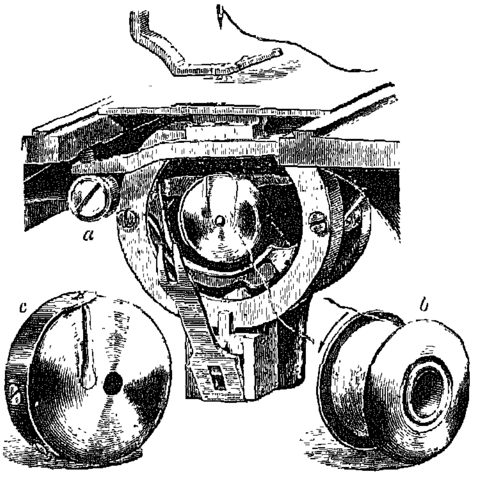

Fig. 5.
a, bobbin-holder, rotating-hook, &c.; *b*, bobbin; and *c*, bobbin-case.

The German universal feed cylinder sewing-machine, a lock-stitch machine which feeds in every direction and which by its small cylindrical arm is adapted to repairing of shoes, glove manufacturing, and pocket-book manufacturing, has an automatic device attachment by which it duplicates any number of patterns of circular stitching. About 2½ or 3 yards of thread are required to one yard of sewing for the 'lock-stitch,' being about half the quantity required by the 'double-loop stitch' machines. Some of the lock-stitch machines will make a single chain-stitch if we remove the under thread device and substitute a looper using but one thread.

The button-hole machine makes the 'whip-stitch' of the button-hole and also the 'pearl-edge stitch.' It is a wonderful piece of mechanism — impressing one as almost possessing conscious intelligence. It works automatically, cuts its own button-hole, works the button-hole before or after it is cut, cords the button-hole, and bars the end, heavy or light as required, and stops automatically when the hole is completely worked. The machine will work 6000 holes in a day, taking 1500 stitches per minute, and is capable of being used upon the leather shoe or glove, or upon cloth of either light or heavy weight. The stitch is substantially a lock-stitch, the under thread being thrown up upon the edge of the button-hole. There are several machines of this class, and this stitch is secured by a 'button-hole attachment' adjusted to a family machine.

The Singer carpet-sewing machine is manufactured under the Joseph Hesse original base patent for straddling a carpet—supplemented by re-issue patent in 1879, also the patents for improvement on same machine by G. Grisel in 1884 and 1885. While other sewing-machines feed the goods, this is the reverse. While the goods remain stationary, the operator, holding the machine with one hand, with the other turns the crank, which in turn moves a right and left feed-wheel in the straddling plates. These feed-wheels take hold of the carpet and force the machine forward fast or slow as the crank is turned. The stitch is made with a curved needle and looper. The machine may be operated by a lady; the carpet is secured by clamps, and a durable overseam is produced. Ingrain, hemp, Brussels, velvets, moquettes, or Axminsters are sewed with equal facility.

Machines have been invented for taking the 'back-stitch,' the 'basting or running' stitch, the through-and-through stitch known as the 'cordwainer's' stitch, the over-and-over stitch; indeed every stitch used in plain and fancy needlework except the 'blind' or 'hemming' stitch.

The hemming stitch must not be confounded with 'hem-stitching,' a well-known process by which certain threads of the 'filling' of cloth are drawn, and the warp artistically wrought into clusters or groups of threads by the use of the needle. The hem-stitching effect is produced upon the sewing-machine by the weaving of the thread alternately through the edges of adjacent pieces of

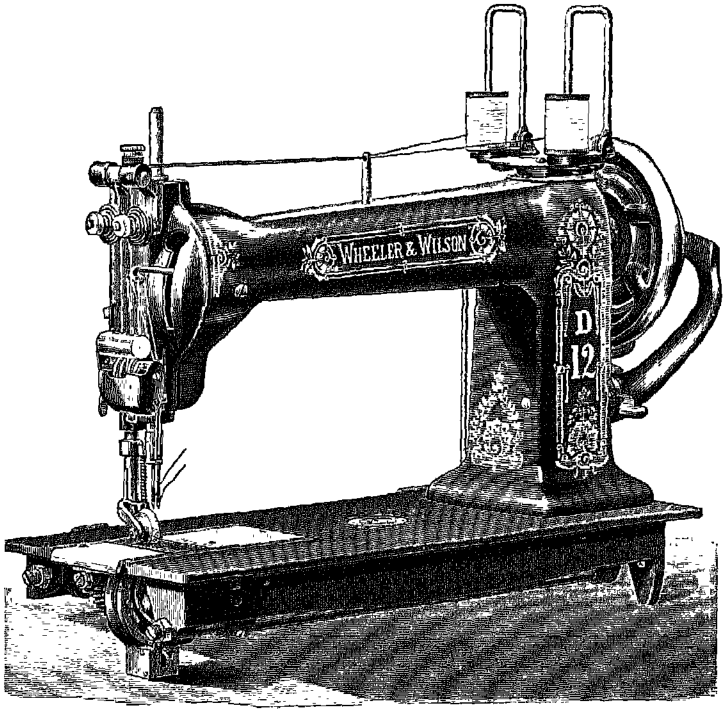

Fig. 6.—Head of Wheeler & Wilson's No. 12 fitted up with two upper threads.

cloth, then by the lock-stitch, sewing the threads through the centre, by stitches lengthened for the purpose of producing the effect desired. By a similar process, the skilled operator can readily produce lace in beautiful and artistic designs; and the effects of old tapestry may even be produced by the use of the sewing-machine.

History.—The idea of the sewing-machine originated in England during the 18th century, but as an invention of practical utility it is a product of the 19th century, and of the United States of America. In June of 1755 Charles F. Weisenthal patented a needle in England, having an eye in the centre, and being pointed at both ends. It was intended for hand embroidery, but was subsequently used in some of the earlier sewing-machines. Robert Alsop in 1770 patented in England a device for embroidering with one, two, or more shuttles. This was followed in 1804 by a machine, invented and patented by John Duncan, for embroidering, consisting of a large number of barbed or hooked needles set in a horizontal bar, and supplied with thread by a feeding needle. By a forward motion of this bar the needles were simultaneously carried through the fabric, and by the reverse motion were again brought back, passing through the loop of thread made by the previous stitch, thus making a 'loop-stitch.' This machine was subsequently improved by Mr Heilman, and extensively used for embroidery purposes.

Meanwhile, in 1790, a patent was taken out in England by Thomas Saint 'for quilting, stitching, and making shoes, boots, spatterdashes, clogs, and other articles.' This machine used a single thread, made a loop-stitch, the loops being upon the outer side of the fabric, had a perforated awl by which the hole for the needle was made, and was worked by a combination of 'cogs,' 'prongs,' 'wheels,' and 'spindles.'

In 1834 M. Thimonnier, a Frenchman, secured a patent in England for a crocheting-machine for sewing purposes, which made a loop-stitch by means of a hooked needle that had to be passed through the cloth backward and forward twice in order to make one perfect stitch. This machine improved was subsequently patented in France, and in 1851 in the United States. In 1871 Archbold and Newton secured a patent for sewing or stitching the backs of gloves, with the ornamental or tambour stitch, the tension being regulated by passing the thread over a roller covered with cloth, and by the alternate rising and falling of a bar across the thread, the latter acting as the modern *take-up*, and securing uniformity in the degree of tightness of the thread. The *feed* was a rack-and-pinion motion by which the material secured between two metal clamps, through which were openings for the needle, was moved forward as the stitching proceeded. In 1842 J. Greenough of Washington secured a patent in the United States for a machine for sewing shoes. This machine made the 'through-and-through' stitch, or 'shoemaker's stitch,' represented in fig. 7, using a single thread in the eye of Weisenthal's needle, *a*, the needle being drawn through backward and forward by means of pincers upon each side of the material. There was neither 'chain,' 'loop,' nor 'lock' by which the firmness and durability of the 'hand-sewed' shoe or of the ordinary 'back-stitch' for garments was secured, and hence this machine could not be adapted for general sewing. In 1843 B. W. Bean of New York patented a machine making the 'running' or 'basting' stitch, a stitch similar to the 'through-and-through' stitch, but by quite a different device (see figs. 7 and 8, and compare) and designed for a different class of fabric. Fig. 8 represents the device used in the machine for the making of the running stitch. The needle, *a*, is long and stationary, with the eye and point at opposite ends, as in the ordinary needle for hand-sewing, and receiving a continuous supply of thread from the reel, *b*; the two small toothed wheels, *c*, are so arranged that their teeth pressing into one another crimp the two pieces of cloth, *d*, and push them forward against the needle-point, the operator drawing off the cloth from the needle at the eye end as rapidly as it is filled. This machine was extensively introduced into England, and used by bleachers, printers, and dyers for temporary basting, and for loose tacking of pieces of stuff.

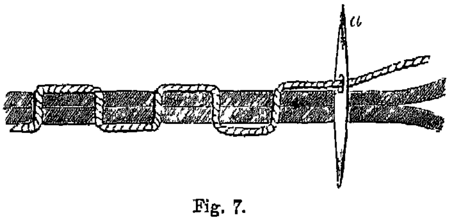

Fig. 7.

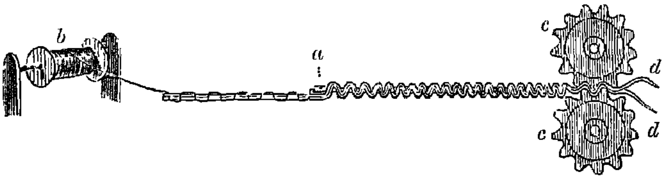

Fig. 8.

The machine destined to revolutionise the sewing world and play a most important part in future industries was not yet conceived. The thought of the inventor had been centred apparently upon facilitating the embroidery of various articles of household and dress ornamentation, excepting the effort to lessen the labour of making shoes. Walter Hunt of New York is said to have constructed a machine for taking the lock-stitch in 1832 or 1834. However, to Elias Howe (1819-67), of Cambridge, Massachusetts, belongs the credit of constructing and patenting the first lock-stitch sewing-machine. Compared with the almost perfect machines of to-day, this machine was indeed a crude effort; it however formed the basis of the present lock-stitch sewing-machine, and comprised its essential features. It was patented in 1846, although possibly constructed earlier. Mr Howe combined a needle having the eye near the point vibrating in the direction of its length, though horizontally, with a shuttle device vibrating horizontally, yet so as to pass through the loop made by the thread in the needle eye being carried through the cloth, then drawn backward in the opposite direction; together with the 'sawmill carriage' 'feed motion,' and a baster-plate and projecting pins holding the cloth as in metal clamps in a vertical position while being stitched. The stitch formed by the two threads, one upon each side of the fabric, drawn in a 'double interlocked loop' in the centre of the material, presents the appearance of a single thread in regular stitches, exactly the same upon both sides of the cloth, and is essentially the lock-stitch of the more modern machine. The needle of the

Howe machine was a great invention, without which no sewing-machine is possible; improvements were, however, soon made in the 'setting' of the needle, substituting the vertical motion of the needle for the horizontal motion of the original machine, thus passing the cloth upon the table of the machine horizontally under the needle, together with a 'wheel feed motion' beneath the baster-plate, by which the cloth was moved horizontally from left to right. Subsequently the shuttle was made to describe an entire circuit instead of the former oscillating or vibrating motion. This latter improvement was made and patented by Blodgett & Heron of Boston in 1849; but while it effectively economised power, it was soon found impractical because of the untwisting of the thread as the shuttle rotated. In 1850 Allen B. Wilson of Pittsfield patented a 'double beak shuttle,' by which a complete stitch was made at each forward and backward motion of the shuttle, which also economised power. About the same time Robinson of Boston patented a machine having two needles curved, which being threaded with short threads, one upon each side of the cloth, were passed alternately through the cloth, and the thread drawn each way, making the cordwainer's stitch. By this machine the back stitch and the basting stitch could be made.

In 1851 Mr Wilson invented and patented the 'rotating hook' device (see fig. 4), a device new in machinery and an effective substitute for the shuttle. Mr Wilson also made a most substantial improvement in his lock-stitch rotary motion machine, known as the 'four-motioned feed' or 'rough surface feed with yielding pressure,' which has since been adopted by all sewing-machine manufacturers for all flat-bed work. It consists of a horizontal slotted bar placed between the standards which support the cloth plate, with a 'feed-tongue,' which fills the slot, and is pivoted at one end, but free at the other end for an up-and-down motion. The *four* motions are an upward or lifting motion by which the teeth are fixed in the cloth, a forward motion by which the cloth is moved forward, a downward motion by which the teeth loose their hold upon the cloth, and a backward motion effected by a spiral spring at the other extremity of the feed-bar. The length of the stitch is determined by the play of the feed-bar. By the successive motions of this rough surface feed, the only hold upon the cloth while the needle is passing down through the cloth is the needle itself; hence the cloth may be turned in any direction by the operator without stopping the machine, an advantage which will be readily appreciated, making it possible to turn corners while sewing. In 1849 a 'chain-stitch' machine was patented by Morey and Johnson, in which the cloth was suspended from a circular baster-plate, the thread being carried through the cloth by the horizontal play of the needle. This machine was subsequently improved by J. E. A. Gibbs of Virginia, and as improved is known as the Wilcox & Gibbs machine. The double loop-stitch machine before described was invented and patented by W. C. Grover and W. E. Baker of Boston in 1852. Immediately after the Singer machine, bearing the name of the inventor, was patented. It was an improvement upon the original Howe machine, and it in turn has been improved from time to time with various patents, until, as we have seen, it is one of the leading machines. Its automatic self-adjusting belt is one of its recent patents. In 1856 Chapin secured a patent for the 'hemmer,' a device of steel consisting of a 'scroll' or 'gauge' set in a steel 'presser-foot,' by which the hem or fell is turned. It is an attachment adapted to any sewing-machine. Various patents have been secured for the various attachments and improvements from time to time, and also for new machines adapted to special classes of work, the number in the United States alone amounting to many hundreds, and still a large number of devices for sewing-machine appliances are patented annually.

The button-hole machine was invented and patented in 1882 by Ostrom, and almost at once materially improved by Horace Doggett, a young man under twenty, by the addition of an 'automatic cutter.' This device was patented, and was subsequently purchased by the Wheeler and Wilson Company. Attachments for the working of button-holes have been patented, adapted for use upon any sewing-machine. The button sewing-machine is also a recent invention, of which there are a variety of devices patented.

Immediately after the invention of the Singer machine litigation arose between the various inventors, and terminated in 1854 in a sewing-machine combination, by which all companies united in the use of the Howe needle and the Wilson four-motioned feed, paying to their inventors a royalty. Mr Howe's royalties amounted to over $2,000,000; Mr Wilson also amassed a large fortune from his four-motioned feed patent, which patent ran out in 1878, the last of the important original patents to run out. Immediately sewing-machines were reduced in price fifty per cent.

The sewing-machine of to-day is fitted up with an open or closed cabinet with or without drawers elaborately finished in expensive woods, the machine being of the same quality in all cases. A large amount of capital is invested in the sewing-machine manufacture, and many thousands of machines are annually made, there being from 6,000,000 to 8,000,000 now in use. The Singer Manufacturing Company is the largest manufacturing company, having factories at Elizabethport, New Jersey, at Kilbowie, near Glasgow, at Vienna, and in Canada. The main factory of the Wheeler and Wilson Company is in Bridgeport, Connecticut, and its machines are extensively used in Great Britain and other European countries.

Sex. In all the many-celled animals, and in most of the many-celled plants, the continuance of life from generation to generation is secured by special reproductive cells which form new lives, being sooner or later separated from the body of the parent. In this specialisation of reproductive cells lies the great difference between sexual and asexual reproduction. But in the great majority of organisms the special reproductive cells are of two kinds—there are relatively large and passive ova, and relatively small and often very active spermatozoa. These two kinds of reproductive cells are mutually dependent; in most cases they die unless they unite with one another. When this union or fertilisation takes place a new life begins. But in most organisms the ova are formed in one organ, the spermatozoa in another, while in most animals, and in all the higher forms, the ova are formed by one individual (a female) and the spermatozoa by another (the male)—there being, in other words, two distinct sexes. Moreover, the males and females differ not only in their essential characteristics of producing spermatozoa and ova respectively, but they often differ very markedly in external appearance, constitution, and habits. Further, they are instinctively attracted to one another in such a way that the union of the complementary reproductive cells is secured.

It is evident then that the fact of sexual reproduction involves many distinct biological problems: (*a*) the formation of specialised reproductive cells; (*b*) the origin of two different kinds of reproductive cells—ova and spermatozoa; (*c*) the differentiation of distinct organs or of two distinct types of individual for the production of these two kinds of elements; (*d*) the divergence between the sexes in secondary as well as in essential characteristics; and (*e*) the evolution of the sexual instincts which find their highest expression in the love and courtship of many of the higher animals. As the general problem of sexual reproduction is discussed in the article REPRODUCTION, and as the divergent modes of sexual reproduction are discussed in special articles, such as HERMAPHRODITISM and GENERATIONS (ALTERNATION OF), we shall confine ourselves here to the problems immediately connected with the evolution of sex.

What is the meaning of the existence of two distinct sexes? The problem may be approached in several different ways. We may, for instance, inquire whether this normal divergence of individuals into two types has any analogue among other cases of divergent variation among organisms. To some the analogy seems not far to seek. For throughout organic nature a great contrast may be read, between plant and animal, Gregarine and Infusorian, coral and jellyfish, barnacle and shrimp, coccus-insect and fly, slug and Pteropod, tortoise and lizard, reptile and bird, and even more clearly between related genera or even related species; a contrast between predominant passivity and activity, between a storing and constructive physiological habit and one which is prone to expenditure and disruption; a contrast expressible in technical language as an antithesis between a relative anabolic and a relative katabolic preponderance in the protoplasmic life of the creature. Now it may be that the difference between the sexes, between the relatively passive female and the more energetic male, is an expression of what is really a fundamental alternative in variation.

Or we may take a survey of the contrasts between the sexes, and endeavour, after making allowance for the special conditions of each case, to reach some average truth. Then we find that females tend to be larger, more sluggish, less brightly coloured and decorative, that they often have a longer life and sometimes a higher temperature; and that males, on the other hand, tend to be smaller, more energetic, more brightly coloured and decorative, and so on. Now, these characteristics, when physiologically analysed, tend to corroborate the theory that the females and males are individuals of relatively anabolic and relatively katabolic constitutions.

Again, we may approach the problem by inquiring into the physiological conditions which tend in each birth to determine whether the individual will be a male or a female. In many cases—e.g. in amphibians, birds, and mammals—the young life is for some time—usually of very short duration—potentially bisexual; it is believed that surrounding conditions, especially of nutrition, acting upon some constitutional predisposition, determine the predominance of either maleness or femaleness. It is true that we have but incomplete knowledge of this matter, but there are many facts which suggest that influences of food, temperature, &c., which favour anabolism in the parents, embryos, and young, tend to result in female offspring, while opposite factors tend to produce males. Thus by abundant and rich nutrition Jung raised the percentage of females in a brood of tadpoles from 56 to 92, and starved caterpillars tend to become male butterflies or moths. Or again, we may fix our attention on the characteristic products of the sexes—on the ova and spermatozoa. Here the difference between female and male has its fundamental and most concentrated expression. For the ova are relatively large cells, very passive, and usually rich in reserve-products, while the spermatozoa are very minute cells, usually very active, rarely with any reserve-products. In short, the ova (like the females) are relatively anabolic, and the spermatozoa (like the males) are relatively katabolic.

We should also inquire into the beginnings of sexual differentiation among the simpler forms of life. Among the unicellular Protozoa, in which sexual reproduction in the strict sense cannot occur, there are already the analogues of males and females, as we see for instance in Vorticella, when a small free-swimming individual unites with a stalked cell of normal size. Very gradual among the simple plants also are the steps of sexual differentiation. But of especial importance is the genus Volvox—a colony of loosely united cells—in many ways related to the Flagellate Infusorians. In this globular colony division of labour is at a minimum, and individuals often occur which are quite asexual, forming daughter-colonies, without specialised reproductive cells. Others have, among the other units of the colony, special reproductive cells, which are, however, parthenogenetic, able of themselves to form new colonies. Others have special reproductive cells—ova and spermatozoa—formed within the same colony, but usually maturing at different times. Then there are colonies in which only ova are formed, and others in which only spermatozoa are formed, cross fertilisation taking place as usual. And besides these various sexual conditions other combinations often occur in the same species of Volvox, in which we can indeed read, and with increasing physiological knowledge will more fully understand, almost the whole story of the evolution of sex.

Finally, it must be observed that the origin of two kinds of reproductive cells which combine in fertilisation, and the specialisation of two types of individual as the bearers of ova and spermatozoa respectively, must have been of advantage in the general evolution of organisms. For, as almost every life begins in the mingling of two distinct reproductive units produced by two distinct types of individual, there is here one of the most important sources of variation and one of the most important means of securing the average stability of the species.

But we must also recognise the psychical expression of sex—the love of mates. This also has its history. Among crustaceans and insects first, in fishes and amphibians, in reptiles too, but most markedly among birds and mammals, the males are attracted to the females, and enter into relations of helpfulness with them. The relations and attractions may be crude enough to begin with, but to mere physical fondness are added subtler attractions of sight and hearing, and these are sublimed in birds and mammals to what we call love. This love of mates broadens out; it laps the family in its folds; it diffuses itself as a saturating influence through the societies of animals and of men.

See REPRODUCTION, SEXUAL SELECTION, and *The Evolution of Sex*, by Prof. Geddes and the present writer (1889), with a bibliography of the subject.

Sexagesimals. See SCALES OF NOTATION.

Sexagesima Sunday (Lat. *sexagesima*, 'sixtieth'). See QUINQUAGESIMA.

Sextant, an instrument for measuring the angular distance of objects by means of reflection. The principle of its construction depends upon the theorem that, *if a ray of light suffer double reflection, the angle between the original ray and its direction after the second reflection is double of the angle made by the reflecting surfaces.* Thus, let A and B (fig. 1) be two mirrors perpendicular to the same plane, and inclined to each other, and let SA be a ray of light, which falling upon A is reflected on B, and re-reflected in the direction BC, then

ACB is the angle between the original and finally reflected rays, and ADB is the angle between the mirrors. Now, as the angle of reflection is equal to the angle of incidence, $\angle$ SAF = $\angle$ BAD, and $\angle$ GBA = $\angle$ DBC; but $\angle$ EBC = $\angle$ BAC + $\angle$ BCA = ($\angle$ BAD + $\angle$ DAC) + $\angle$ BCA = ($\angle$ BAD + $\angle$ SAF) + $\angle$ BCA = 2 $\angle$ BAD + $\angle$ BCA; and $\angle$ EBC also = $\angle$ EBD + $\angle$ DBC = $\angle$ EBD + $\angle$ GBA = 2 $\angle$ EBD = 2 $\angle$ BAD + 2 $\angle$ BDA; therefore $\angle$ BCA = 2 $\angle$ BDA, which proves the truth of the theorem. The instrument of which this theorem is the principle is a brass sector of a circle in outline; the sector being the sixth part of a complete circle, for which reason the instrument is called a *sextant.* Fig. 2 shows the essentials of its construction; AMN is the sector whose curved side, MIN, is the sixth part of a circle; A is one mirror wholly silvered, placed perpendicular to the plane of the sector, and on, and in line with, the limb AI, which is movable round a joint at or near A; B is the other mirror, also perpendicular to the plane of the instrument, and silvered on the lower half only, the upper half being transparent; E is an eyelet-hole or small telescope. The graduation runs from N to M (on a slip of silver, platinum, or gold let into the rim), and is so adjusted that, when the movable limb is drawn towards N till the mirrors A and B are parallel, the index which is carried at the foot of the movable limb is opposite zero on the graduation. If we suppose that this zero-point is at N, it is evident that the angle between the mirrors is equal to the angle NAI; and again, if instead of graduating from 0° at N to 60° at M, which is the proper graduation for the sixth part of a circle, the graduation be made from 0° to 120°—i.e. each half degree being marked as a degree, and similarly of its aliquot parts—then the angle NAI, read off by the index at I, will show at once the angle between the incident and finally reflected rays. The mode of using the sextant consists in placing the eye to the telescope or eyelet-hole, and observing one object directly through the unsilvered part of B, and then moving the index till the image of the other object, reflected from A upon the silvered part of B, coincides with or is opposite to the first object; then the angle, read off at I, gives the angle between the objects. For additional accuracy a vernier is attached to the foot of the movable limb.

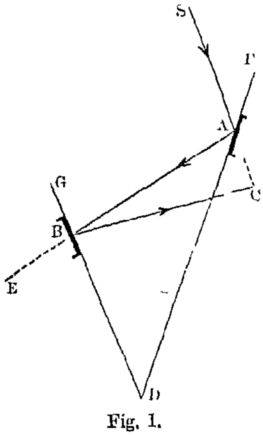

Fig. 1.

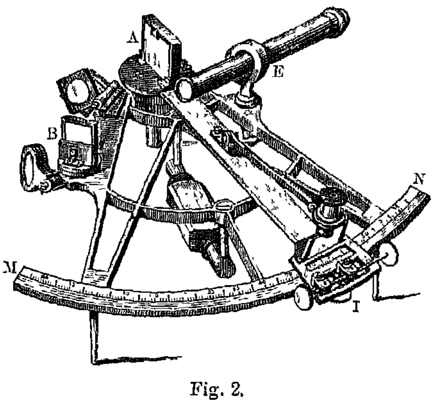

Fig. 2.

The sextant is capable of very general application, but its chief use is on board ship to observe the altitude of the sun, the lunar distances, &c., in order to determine the latitude and longitude. For this purpose it is necessary to have stained glasses interposed between the mirrors A and B, to reduce the sun's brightness. These glasses (generally three in number) are hinged on the side AM, so that they may be interposed or not at pleasure. B is the glass through which the horizon is perceived, and has hence received the name of the *horizon-glass;* while the other mirror, from its being attached to the index-limb, is called the *index glass.*

The sextant is liable to three chief errors of adjustment: 1° if the index glass be not perpendicular to the plane of the instrument; 2° if the horizon-glass be not perpendicular to the plane of the instrument; and 3° if, when the mirrors are parallel (which is the case when a very distant body, such as the sun or moon, is observed directly through B, and found to coincide with its image in the lower part of B), the index does not point accurately to 0°; this last is called the *index-error,* and is either allowed for, or is remedied by means of a screw, which moves the index in the limb AI, the latter being stationary. The first two errors are also frequently remedied by means of screws working against a spring, but in the best instruments the maker himself fixes the glasses in their proper position.—The *quadrant* differs from the sextant only in having its arc the fourth part of a circle, and being consequently graduated from 0° to 180°; the *octant* contains 45°, and is graduated from 0° to 90°; while the *repeating-circle,* which is a complete circle, is graduated from 0° to 720°. A common form of the sextant is the 'snuff-box' sextant, which is circular in shape, and, as it can be conveniently carried in the pocket, is the form most frequently used by land surveyors.

The idea of a reflecting instrument, on the principle of the sextant, was first given by Hooke about 1666; but the first instrument deserving the name was invented by John Hadley (q.v.) early in the summer of 1730, and a second, and much improved form of it, was made by him a short time afterwards. Halley, at a meeting of the Royal Society, claimed for Newton the priority of invention, and in October 1730 a Philadelphian, named Godfrey, also asserted his claim as the original inventor; but that learned body decided that Newton's claim was unsupported by even probable evidence, and that Hadley's and Godfrey's inventions were both original, but that the second form (which is almost the same as the common sextant now employed) of Hadley's instrument was far superior to his first form and to Godfrey's. See works by H. W. Clarke (1885) and C. W. Thompson (1887).

Sexton (corrupted from Sacristan, q.v.) is a parochial officer in England, whose duty is to take care of the things belonging to divine worship. He is usually chosen by the inhabitants, but often also by the clergyman or the churchwardens, the mode of appointment being regulated by the custom of each parish. He sometimes also holds the office of parish-clerk. Women have occasionally been appointed sextons (e.g. at Kingston-upon-Thames, 1731; Donnybrook, near Dublin, 1845–56; and the adjoining parish of Booterstown, 1856–74). The office is a freehold office for life, except in the new parishes under Church-building Acts; the duty is to keep the church clean, swept, and adorned, to open the pews, to make and fill up the graves, and to prevent any disturbance in church. The salary is usually paid by the churchwardens, and as to amount depends on custom. In Scotland he may also be beadle or 'church-officer,' although the latter's duties are usually connected with attendance on the minister.

Sextus Empiricus, physician and philosopher, lived at Alexandria and Athens about 200-250 A.D. As physician he was a representative of the Empirics (hence his second name; see MEDICINE); as philosopher he was the chief exponent of the later Scepticism (q.v.) of the Old World, which was professedly a continuation of Pyrrhonism. In his two works still extant—the *Hypotyposes* and *Adversus Mathematicos*—he has left a prodigious battery of arguments and exceptions against dogmatism in grammar, rhetoric, geometry, arithmetic, music, astrology, logic, physics, ethics. There are monographs by Jourdain (Paris, 1858) and Pappenheim (Berlin, 1875).

Sexual Selection is a term applied by Darwin to the process of favouring and eliminating which to some extent occurs in the mating of many animals. It is a special case of natural selection, depending upon a competition between rival males, in which a premium is set upon those qualities which favour their possessors in securing mates. This competition takes two forms: on the one hand, rival males, for instance stags and gamecocks, fight with one another, and the conquerors have naturally the preference in mating; on the other hand, rival males sometimes seem to vie with one another in displaying their attractive qualities before their desired mates, who, according to Darwin, choose those that please them best.

Darwin gives the following summary of his theory: 'It has been shown that the largest number of vigorous offspring will be reared from the pairing of the strongest and best-formed males, victorious in contests over other males, with the most vigorous and best-nourished females, which are the first to breed in the spring. If such females select the more attractive and, at the same time, vigorous males, they will rear a larger number of offspring than the retarded females, which must pair with the less vigorous and less attractive males. So it will be if the more vigorous males select the more attractive and, at the same time, healthy and vigorous females; and this will especially hold good if the male defends the female, and aids in providing food for the young. The advantage thus gained by the more vigorous pairs in rearing a larger number of offspring has apparently sufficed to render sexual selection efficient.'

Where there is direct competition between males, the weakest will tend to be eliminated, either directly by death or injury in the struggle, or indirectly by diminished success in reproduction. In the same way, if a male be lacking in the qualities necessary to find a mate—e.g. in senses acute enough to find out her whereabouts—that male may remain unreproductive. But there is not enough of evidence to enable us to compute how many males do remain unmated in consequence of non-success in competition.

In regard to the second aspect of sexual selection, in which the females are believed to exercise some choice, giving the preference to those suitors which have brighter colours, more graceful forms, sweeter voices, or greater charms of some kind, there is no little difference of opinion. Darwin indeed believed strongly in the female's choice, and referred to this process of selection many of the qualities which distinguish male animals. The females 'have by a long selection of the more attractive males added to their beauty or other attractive qualities.' 'If any man can in a short time give elegant carriage and beauty to his bantams, according to his standard of beauty, I can see no reason to doubt that female birds, by selecting during thousands of generations the most melodious or beautiful males, according to their standard of beauty, might produce a marked effect.' On the other hand, Alfred Russel Wallace maintains a very different position. 'There is,' he says, 'a total absence of any evidence that the females admire or even notice the display of the males. Among butterflies there is literally not one particle of evidence that the female is influenced by colour or even that she has any power of choice, while there is much direct evidence to the contrary.' Against this, G. W. and E. G. Peckham, in their careful essay on sexual selection in spiders, state that they have in the Attidæ 'conclusive evidence that the females pay close attention to the love dances of the males, and also that they have not only the power, but the will, to exercise a choice among the suitors for their favour.' Some observers of birds are also confident that the females choose the more musical or otherwise attractive males. But again Wallace maintains that the fact that every male bird finds a mate 'would almost or quite neutralise any effect of sexual selection of colour or ornament; since the less highly coloured birds would be at no disadvantage as regards leaving healthy offspring.' In spiders, however, it seems that the more brilliant males may be selected again and again while the mating season lasts.

The theory of sexual selection is of considerable importance in a general theory of evolution. This may be illustrated in reference to the bright plumage of many birds. If we postulate successive crops of variations (which cannot at present be completely rationalised), if we acknowledge that there is really 'preferential mating' among birds (which is not readily proved or disproved), if we believe that the females are sensitive to the slight excellences which distinguish one suitor from another and that their choice of mates is determined by these excellences (which Wallace emphatically denies), then we may say that the greater brightness of male birds may have been evolved by sexual selection. This was Darwin's opinion. The brighter males succeeded better than their rivals in the art of courtship; the variations which gave them success were transmitted to the offspring; gradually the qualities were established and enhanced as secondary sexual characters of the species. But Wallace interpreted the facts quite otherwise. The relatively plain plumage of the female birds was due to natural selection, eliminating those whose conspicuousness during incubation was fatal, fostering those whose colouring was protective. Just as Daines Barrington, a naturalist still remembered as the correspondent of Gilbert White, suggested (1773) that singing-birds were small and hen-birds mute for safety's sake, so Wallace maintained that female birds had forfeited brightness as a ransom for life.

But, leaving the birds, let us take a case which seems to afford better illustration of Darwin's theory of sexual selection—that of spiders. The courtship of these animals has been observed and described by G. W. and E. G. Peckham in a manner so careful that their paper ranks as one of the most important contributions yet made to the theory of sexual selection. 'The fact that in the Attidæ the males vie with each other in making an elaborate display, not only of their grace and agility but also of their beauty, before the females, and that the females, after attentively watching the dances and tournaments which have been executed for their gratification, select for their mates the males that they find most pleasing, points strongly to the conclusion that the great differences in colour and in ornament between the males and females of these spiders are the result of sexual selection.' It may be that the American observers have, especially in their psychological language, mingled a little imagination with their induction, but they state a strong case for sexual selection.

The conclusions drawn from the courtship of spiders are not affected by Wallace's criticism so seriously as are those which Darwin drew from the courtship of birds, and this suggests that the wisest position is one of compromise, which recognises that in some cases—e g. spiders—the external divergence of the sexes may depend upon sexual selection, and that in other cases—e.g. birds—it may depend rather upon natural selection.

But even with this compromise it is difficult to rest satisfied. For before we can believe that attractively bright ornaments could become characteristic of males by sexual selection, or that protectively plain colouring could become characteristic of females by natural selection, we must assume that the qualities of brightness can be entailed in inheritance on the males only, and the qualities of plainness on the females only. But this fundamental assumption has not yet been justified by a sufficiently strong body of facts.

This difficulty arouses scepticism as to the thoroughness of the explanations of secondary sexual characters suggested either by Darwin or by Wallace. We are not surprised, therefore, to find Mivart's explanation of the beauty of males as the direct expression of an internal force, or Mantegazza's hints as to a physiological explanation of the sexual divergence, or Brooks's reference to 'something within the animal which determines that the male should lead and the female follow in the evolution of new breeds.' Geddes advanced further, endeavouring to interpret the secondary sexual characters as outcrops of the relative preponderance of anabolism and katabolism characteristic of females and males respectively. Gay colouring—sometimes at least due to pigmented waste products—is regarded as a characteristic expression of the predominantly katabolic or male sex, and quiet plainness is equally natural to the more anabolic females. But this theory, which seeks to rationalise the variations which Darwin simply postulated, is by no means inconsistent with a recognition of sexual selection as an accelerant directive process in the evolution of male brightness, or of natural selection as a retardative directive process eliminating disadvantageously conspicuous females.

Wallace has also in his work on *Darwinism* (1889) worked towards a rational interpretation of the variations which he was previously content to postulate as facts. For he says that 'ornament is the natural outcome and direct product of superabundant health and vigour,' and is 'due to the general laws of growth and development.' It seems to some that this mode of interpreting characters is of far-reaching importance, and that it affects not only the theory of sexual selection but that of natural selection as well.

The Peckhams do indeed deny that male spiders possess greater vital activity than the females, and they find no relation in either sex between activity and development of colour. But it must be noted that a predominant katabolic diathesis—which is, according to Geddes, the fundamental characteristic of maleness—may be true of male spiders though not expressed in greater vital activity.

We must of course be careful to distinguish that the suggestions made by Geddes, Wallace, and others as to the physiological meaning of sexual characters have to do with primary factors in evolution—i.e. with those which originate variations—while the explanation of the differences in plumage between male and female birds, either by the theory of sexual selection (according to Darwin) or by natural selection (according to Wallace), have to do with secondary factors in evolution—i.e. with those which foster or eliminate variations. Apart from the problem of the origin of the sexual variations the central question with regard to sexual selection by preferential mating is, as Lloyd Morgan says, what guides the variation along special lines leading to heightened beauty. 'Sexual selection by preferential mating involves a standard of taste; that standard has advanced from what we consider a lower to what we consider a higher æsthetic level, not along one line but along many lines. What has guided it along these lines?'

To sum up, the problems involved in sexual selection are (1) what physiological conditions explain the secondary sexual characters which so often distinguish males and females; (2) to what extent and in what degrees of refinement does preferential mating occur; and (3) to what extent has sexual selection guided the differentiation of the sexes alike in distinctive qualities and in æsthetic sensitiveness? Before these problems can be adequately solved many more facts must be accumulated.

Seychelles, a group of islands belonging to Great Britain, and administered by an officer (assisted by an executive council of three members and a legislative council of five) acting under the governor of Mauritius, are situated near the middle of the Indian Ocean, 600 miles NE. of Madagascar. There are thirty larger islands and numerous smaller ones, their total area being 78 sq. m., of which 59 belong to Mahé, the largest (17 miles broad by 7 long) and most important of them. Next in size and importance come Praslin, Silhouette, La Digne, Curieuse, Bird, Frigate, and Denis. They get their French names from having been first colonised by the French in 1742, though they were known to the early Portuguese navigators. The British wrested them from the French at the same time they took Mauritius (1794), and they have held them ever since. The islands are mountainous, and in Mahé reach close upon 3000 feet. Coral-reefs grow round most of the islands, and the coral is used for house-building. The climate, though tropical (range of thermometer 70° to 93° F.), is tempered by the proximity of the sea, and is very healthy. The soil is fertile and vegetation luxuriant. The principal products and exports are the fibres, nuts, and oil of the cocoanut palm; but maize, manioc, tobacco, coffee, vanilla, cloves and other spices are grown to some extent, and vanilla, cloves, tortoiseshell, soap, and vacoa bags are exported. The exports increased in value from £27,800 in 1884 to £39,260 in 1889. The Coco de Mer (*q.v.*) is peculiar to Praslin and one or two more of these islands. Gigantic tortoises, and the edible black tortoise, resort to certain islands of the group. The imports, consisting chiefly of cotton, haberdashery, coal, spirits and wine, and provisions, increased from £29,960 in 1884 to

£49,900 in 1889. Victoria, the chief town on Mahé, is an imperial naval coaling station, and is visited by the Messageries Maritimes steamers and by merchant vessels for coal. Pop. of islands (1881) 14,081; (1890) 16,162—chiefly French creoles, Indian coolies, negroes, and British officials. See Horne, *Report on the Seychelles Islands* (1875).

Seymour, a city of Indiana, 88 miles by rail W. of Cincinnati, with manufactures of woollens, flour, staves, spokes, &c. Pop. (1890) 5307.

Seymour, an historic family, originally settled in Normandy at St Maur—whence the name. Coming over to England, they obtained lands in Monmouthshire as early as the 13th century, and in the 14th at Hatch Beauchamp, Somersetshire, by marriage with an heiress of the Beauchamps. In 1497 Sir John Seymour helped to suppress the insurrection of Lord Audley and the Cornish rebels, and subsequently he accompanied Henry VIII. to his wars in France, and to the Field of the Cloth of Gold. His daughter, Jane Seymour (*c.* 1509–37), became the wife of Henry VIII. and mother of Edward VI.; and his second son, Thomas, created Lord Seymour of Sudeley, became Lord High Admiral of England and the second husband of Henry's widow (Catharine Parr), but ended his life on the scaffold (1549). Sir John's eldest son, Edward, was successively created Viscount Beauchamp, Earl of Hertford, and Duke of Somerset, and as Protector played the leading part in the first half of the reign of Edward VI. (q.v.). The Protector's eldest son by his second marriage, being created by Elizabeth Earl of Hertford, married the Lady Catharine Grey, a grand-niece of Henry VIII., and sister of the unfortunate Lady Jane Grey—a marriage which entailed on him a nine years' imprisonment and a fine of £15,000. His grandson, who in 1621 succeeded him in the earldom of Hertford, also fell into disgrace for attempting to marry the Lady Arabella Stuart, cousin of James I.; but subsequently, playing a conspicuous part in the royalist cause in the Great Rebellion, obtained a reversal of the Protector's attainder, and in 1660 took his seat in the House of Peers as third Duke of Somerset, although the descendants of the first duke, by his first marriage, were then in existence. He died unmarried in 1671, and the ducal title ultimately passed to a cousin, on whose death it was inherited by Charles Seymour (1661–1748), known in history as the 'Proud Duke of Somerset,' a nobleman whose style of living was ostentatious and haughty in the extreme, and who filled several high posts in the courts of Charles II., William III., and Anne. He married the heiress of the Percies, by whom he had a son, Algernon, seventh duke, who in 1749 was created Earl of Northumberland, with remainder to his son-in-law, Sir Hugh Smithson, the ancestor of the present Percy line. On the death of this duke in 1750 a curious peerage case arose, the title being claimed by the descendants of the first duke by his first marriage; and the attorney-general having reported in favour of the claim, Sir Edward Seymour took his seat in the House of Peers as eighth duke. The earldom of Hertford, which became extinct in 1750, was in that same year conferred on this eighth duke's first cousin, Francis, who in 1793 was advanced to the dignity of Marquis, and one of whose great-grandsons, Sir Frederick Beauchamp Paget Seymour, admiral R.N., was in 1882 created Baron Alcester for his services at the bombardment of Alexandria.

Seyne, La, a seaport of France (dept. Var), on the Mediterranean, 3 miles SW. of Toulon. Here are fine shipbuilding-yards, employing 2000 men, and a spacious harbour. Pop. 9340.

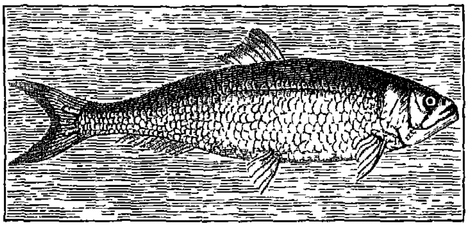
Sezze (anc. *Setia*), a city of Italy, situated immediately north of the Pontine marshes and 40 miles SE. of Rome, has a Gothic cathedral and ruins of a great temple to Saturn, an amphitheatre, &c. Pop. 6114.

Sfax, the second port in the regency of Tunis, is situated on the Gulf of Cabes, 150 miles S. by E. of the town of Tunis, and is surrounded by gardens and suburban villas. The Mohammedans, the Europeans, and the Jews each live in separate quarters; the French camp forms a fourth division. There is an active trade in dates, olive-oil, esparto grass, wool, fruits, sponges, &c., the port being entered by 1100 to 1600 vessels of 224,000 to 237,000 tons annually. Large quantities of fruit are grown, and cottons, woollens, and silks are manufactured. Pop. 30,000. The town was bombarded by the French in 1881, the opposition here being fierce and fanatical.

Sforza, a celebrated Italian family during the 15th and 16th centuries, the founder of which was a peasant of Cotignola, in the Romagna, by name Muzio Attendolo (1369–1424), who from a woodcutter became a great *condottiere* and received from Count Alberigo de Barbiano the name of Sforza ('Stormer'—i.e. of cities). He speedily found himself the independent leader of a band of condottieri, and as constable to Queen Joanna II. was one of the main supports of the kingdom of Naples. His natural son, Francesco Sforza, then twenty-three, succeeded, and, as was the custom of the time, sold his sword to the highest bidder, fighting without the slightest scruple for or against the pope, Milan, Venice, and Florence. He invented an improved system of tactics, and it soon came to be taken for granted that victory was certain for the party which he supported. It was thus no great act of condescension in the Duke of Milan, the haughty Visconti, to confer upon him the hand of his only child Bianca and the succession to the duchy. Meantime Sforza took the march of Ancona from the pope (1434), added to it Pesaro (1443), and by a judicious combination of force and stratagem obtained his elevation to the dukedom of Milan (1450) after the decease of his father-in-law. He firmly established his authority over all Lombardy and several districts south of the Po, acquired the esteem of Louis XI., who gave up to him Savona and Genoa, and, after gaining the universal love of his subjects, died 8th March 1466. Though uninstructed he loved and protected letters. Unhappily his successors possessed neither his virtues nor his talents. His son, Galeazzo-Maria Sforza (1466–76), was a tyrant and a monster of debauchery, prodigality, and ferocity, without a single redeeming feature in his character. He was assassinated at the porch of the cathedral of Milan. His son Giovanni-Galeazzo Sforza (1476–94) succeeded, under the regency of his mother, Bona of Savoy, who held the reins of government with a firm hand. But she was forced to give up (1480) her able coadjutor Simonetta to the vengeance of her brother-in-law, Lodovico Maria, surnamed 'the Moor' from his dark complexion; and three days after Simonetta's execution the ambitious Lodovico banished her, and assumed the regency. Finding the young duke in his way, Lodovico put him and his wife, Isabella of Calabria, in prison, and was immediately threatened with attack by the king of Naples, a danger which he attempted to ward off by giving his daughter Bianca, with a dowry of 400,000 ducats, to the Emperor Maximilian I. and by stirring up Charles VIII. of France to assert his claims to Naples. Soon afterwards Duke Giovanni-Galeazzo died, poisoned, as some believe, by his uncle, 20th October 1494. Lodovico-Maria (1494–1500) obtained his investiture as duke, and becoming alarmed at the rapid progress of the French in Italy he joined the league against them, and was rewarded for his perfidy by being driven from his duchy, which was seized by the troops of Louis XII. (1499). The following year he made an ineffectual attempt to regain possession, was made prisoner, and carried to France, where he died in 1510. Of great talents, but low morality, he valued astuteness more than everything else; yet his encouragement of letters and of the fine arts has preserved his name to posterity. His eldest son, MASSIMILIANO SFORZA (1512–15), regained the duchy of Milan after the reverses suffered by Louis XII., and with the aid of the Swiss steadily repulsed the various energetic attempts of the French to recover it; but after the battle of Marignano (1515) he abandoned his rights to the French for a pension of 30,000 ducats, glad to be free from the insolence and exactions of his allies and the attacks of his enemies. His brother FRANCESCO-MARIA SFORZA succeeded nominally to the Milanese after the battle of Pavia, but he was a mere puppet in the hands of Charles V., and on his death, 24th October 1535, and the extinction of the main line of the House of Sforza, the duchy was quietly swallowed up by Austria. The Dukes of Sforza-Cesarini descend from collateral branches of the family. See Ratti, *Della Famiglia Sforza* (1794).

Sgraffito, or SCRATCHED WORK, is the name given to a mode of external wall-decoration practised in Italy, and of which examples have been found in Pozzuoli near Naples, of the date of about 200 B.C. The process is accomplished by means of superimposed layers of plaster applied and operated upon in the following manner. First, the wall having been thoroughly moistened to ensure adhesion, a ¾-inch coat of plaster is floated on, and before it is perfectly dry a ¼-inch skin of black, red, or any other coloured plaster that will not fade is applied; when this is set and while it is still wet, a finishing coat of white plaster is added. A full-sized drawing of the design that is to be realised is then transferred to this outer coating, and the outline cut through to the second coat with a sharp instrument, and made broad or narrow according to the effect desired, and where necessary these incisions are enforced by additional lines as shading. The process is an economical mode of obtaining effect, but like 'fresco' requires to be executed while the material is moist, and therefore no more should be prepared than can be immediately operated upon. Examples of the system are to be found in the choir boys' school of St Paul's Cathedral, the inner court of the Science Schools at South Kensington, some private residences, and the interiors of some churches in England. The application of this principle of decoration is not confined to plaster, but extends also to superimposed metals and to pottery. There are 15th-century specimens of sgraffito pottery in the South Kensington Museum. The examples of house-decoration in Italy are of the 15th, 16th, and 17th centuries.

Shad (*Alausa* or *Alosa*), a genus of fishes of the family Clupeidæ, differing from Clupea (the Herring, &c.) in having the upper jaw deeply notched. The teeth are very small, on the jaws only, and often wanting, at least in the adult fish. The species are numerous, inhabiting the sea, but ascending rivers to spawn. The eggs are small, heavy, and non-adhesive; but they are not buried, like those of the salmon, in the gravel of the river bottom. Shad are very like herrings in form and appearance, and on this account and their large size the British species receive from Scottish fishermen the name of *King of the Herrings*. The herrings of extraordinary size of which the capture is sometimes reported are probably always shad. The Common Shad or Allice Shad (*A. communis*) is rather thicker and deeper in proportion to its length than the herring. It is found on the British coasts and in the lower part of some of the large rivers, more abundantly in the Severn than in any other British river. It attains a length of two or even three feet and a weight of from four to eight pounds. It has no teeth. There is a single black spot behind the gills. Its flesh is of good flavour. The Twaite Shad (*A. finta*) is more plentiful on the British coasts, and is the common shad of the Thames, but the foul state of the river has now made it of very rare occurrence above London. It is smaller than the Allice shad, seldom exceeding 16 inches in length; there are small teeth in both jaws, and a row of dusky spots along each side of the body. The flesh is coarser and less esteemed than that of the Allice shad, but much used for food wherever the fish is plentiful. This species spawns later in the year than the last, and in order to permit it to deposit its spawn its capture in the Thames is prohibited after the end of June. It abounds in many of the rivers of France and other parts of Europe. A species of shad (*Alosa sapidissima*), generally weighing about four or five pounds, but sometimes twelve pounds, is very abundant during some months of the year in some of the North American rivers, as the Hudson, Delaware, Chesapeake, and St Lawrence, and is now bred successfully and in immense numbers in the United States piscicultural establishments.



Common Shad (*Alausa communis*).

Shaddock (*Citrus decumanus;* see CITRUS), a tree, which, like the other species of the same genus, is a native of the East Indies, and which has long been cultivated in the south of Europe. It is said to derive its English name from a Captain Shaddock, by whom it was introduced from China into the West Indies about 1810. It is readily distinguished from most of its congeners by its large leaves and broad-winged leaf-stalk; it has very large white flowers, and the fruit is also very large, sometimes weighing ten or even fourteen pounds, roundish, pale yellow; the rind thick, white and spongy within, bitter; the pulp greenish and watery, subacid, and subaromatic. It is a pleasant, cooling fruit, and much used for preserves. The tree is rather more tender than the orange, but with proper care is often made to produce fine fruit in orangeries in Britain. Finer and smaller than the Shaddock proper is the Pomelo (also called Pummelo, Pompelmoose, and Grape-fruit), a variety rather larger than an orange which bears its fruit in clusters. Both varieties are grown in Florida, and the pomelo is exported thence to the northern states.

Shadows, as ordinarily understood, are the result of the interception of rays of light by opaque or semi-opaque substances. Close inspection of any shadow, whether cast by the sun or by an artificial light, shows that its margin is not clear cut. This is chiefly due to the fact that the source of light has a finite size. There must consequently exist certain regions from which the source of light appears to be only partially screened. In these regions the shadow is partial; whereas in regions from which the source of light is wholly screened by the intercepting substance, the shadow is complete. Other forms of radiant energy may be intercepted, and corresponding shadows cast. Take, for example, sound. To appreciate the existence of sound shadows we must ourselves get within the shadow, that is, we must set ourselves so that a large obstacle intervenes between us and the source of sound. In such circumstances the intensity of the sound becomes very much diminished. The deadening effect of an ordinary wall upon a sound originating at the farther side is a familiar illustration. In electrical radiations shadows also may exist, and may be made evident by suitable means. It should be remembered, however, that a substance which is opaque to one kind of radiation is not necessarily opaque to another. A stone wall is opaque to light, but is not opaque to electrical radiations of a certain kind. Again, rock-salt and glass cast no very apparent light shadows; but with radiant heat glass casts a distinct shadow, while rock-salt casts little or none. See HEAT, and LIGHT; also ECLIPSES.

Shadwell, THOMAS, a dramatic writer of some note in his day, though now only remembered as the 'MacFlecknoe' of Dryden's satire, was born in 1640 in Norfolk. He was educated for the law, but not finding it a pursuit to his mind he deserted it, and after an interval of foreign travel betook himself seriously to literature. His first comedy of *The Sullen Lovers* (1668) had great success, and he continued from year to year to entertain the town with a succession of similar pieces, a complete edition of which was published in four volumes (1720). The immortality which these must have failed to achieve for him he was fated to attain in another way. With Dryden he seems at first to have been on terms of friendly intimacy, and indeed the great poet contributed the prologue to his *True Widow;* but when Dryden flung his *Absalom and Achitophel* and *The Medal* into the cause of the court Shadwell was rash enough to make a gross attack upon him in the *Medal of John Bayes.* Dryden heaped deathless ridicule upon his antagonist in the stinging satire of *MacFlecknoe* and as 'Og' in the second part of *Absalom and Achitophel.* Though his works, hasty and careless as they are, exhibit lively talent and considerable comic force, all that the reading world now knows of Shadwell is that 'Shadwell never deviates into sense.' It was some consolation to succeed his enemy in the laureateship, which in 1688 it became necessary for Dryden to resign. He did not survive long to enjoy it, however, as in 1692 he died—of an overdose of laudanum, it is said.

Shafiites, the name of one of the four principal sects of the Sunnites (q.v.), or 'orthodox' Muslims. Its name is received from its founder, Abu Abdallah Mohammed Ibn Idris, called Al-Shâfiî, from one of his ancestors who descended from Mohammed's grandfather, Abdul Múttalib.

Shaft. See COLUMN.

Shaftesbury (locally *Shaston*), a very ancient municipal borough in Dorsetshire, 3 miles SSW. of Semley station and 22 WSW. of Salisbury. It stands on a narrow chalk ridge, and commands magnificent views over Dorset-, Somerset-, and Wiltshires. The *Caer Palladwr* of the Britons, it was made by King Alfred the seat of a famous abbey of Benedictine nuns (880), whither Edward the Martyr's body was translated in 980, and where Canute died, 1035. At the date of Domesday Shaftesbury had three mints and twelve churches, but four only remain—St Peter's (Norman) the most interesting. Till 1832 Shaftesbury returned two members, and then till 1885 one. Pop. (1851) 2493; (1891) 2122. See Mayo's *Municipal Records of Shaftesbury* (Sherborne, 1891).

Shaftesbury, ANTHONY ASHLEY COOPER, EARL OF, was born on 22d July 1621, at Wimborne St Giles in Dorsetshire, the seat of his mother's father, Sir Anthony Ashley (1551-1628), a clerk of the Privy-council. He was the elder son of John Cooper of Rockborne in Hampshire, who next year was created a baronet. His mother died in 1628, his father in 1631; and though he ultimately came into over £6000 a year, his estate was then torn and rent from him by unjust kinsmen to the tune, he tells us, of £20,000. His boyhood was mostly spent at Cashiobury in Herts, Southwick in Hampshire, and Maddington in Wilts, till at sixteen, having had three tutors, he went up as a gentleman commoner to Exeter College, Oxford, where he 'not only obtained the good-will of the wiser and elder sort, but became the leader even of all the rough young men.' He left without a degree, and in February 1639 married Margaret, daughter of the Lord Keeper Coventry. She died, sore lamented by him, in 1649; and nine months later he married Lady Frances Cecil, the Earl of Exeter's sister, who also dying in 1654, in 1655 he married pious Margaret Spencer, the Earl of Sunderland's sister, who survived him till 1693. Only two sons were born to him, both by his second wife, and one of them died in childhood; but by all three marriages he largely strengthened his family connections.

Meanwhile in 1640 he had entered the Short Parliament for Tewkesbury, but he had not a seat in the Long. A royalist colonel (1643), after ten months' service he went over to the parliament, either from pique or from 'the dictates of a good conscience,' and for nine months more commanded their forces in Dorsetshire, then from 1645 to 1652 lived as a great country gentleman. In 1653 he entered Barebone's parliament, and was appointed one of Cromwell's council of state, but from 1655 he was in opposition, and in 1677 we find him claiming to have 'had the honour to have a principal hand in the Restoration.' He was one of the twelve commissioners sent to Breda to invite Charles II. home, and on the way thither met with the carriage accident which caused him a lifelong internal abscess, but which also in 1666 secured him a lifelong friend in an Oxford student of medicine, John Locke.

For his services he was made a privy-councillor (1660), and next year Baron Ashley and Chancellor of the Exchequer. He served on the trial of the Regicides; proved a diligent minister; supported the war with Holland; and after Clarendon's fall (1667), in which he had no direct share, sided with Buckingham, with whom he formed one of the infamous Cabal, and like whom he was fooled as to the Catholic clauses in the secret treaty of Dover (1669-70). He seems to have opposed the 'stop of the exchequer' (1672), which yet he justified; that same year was made Earl of Shaftesbury and Lord Chancellor (he proved a most upright judge); but in 1673, suddenly espousing the popular Protestantism, supported the Test Bill, which broke up the Cabal.

On 9th October, the Great Seal being demanded of him, he uttered one of his memorable sayings, 'It is only laying down my gown, and putting on my sword;' and, the bribe and the dukedom rejected that were designed to purchase his submission, he ranged himself against Danby as a champion of toleration, but for Dissenters only, and figured thenceforth as a defender of national liberties, or rather, it may be, as an unscrupulous demagogue. He opposed Danby's non-resistance Test Bill (1675), and in February 1677, for his daring protest against a fifteen months' prorogation, was sent to the Tower, whence he was only released a year later on making a full submission. As early as 1674 he had feigned apprehensions of a popish massacre; and though the 'Popish Plot' was not of his forging, but Oates's, he it was that passed the base coin, using that two years' terror (1678–80) against his opponents with a ruthless dexterity that must stamp him for ever with infamy. Not even the Habeas Corpus Act (q.v.), long known as Shaftesbury's Act, is a set off against the judicial murder of Lord Stafford, his personal enemy. Still, for a while he seemed to have completely triumphed. The fall of his rival Danby was followed by his own appointment as president of Temple's new Privy-council of thirty members (April 1679), and James's dismissal to Holland by an attempt to exclude him from the succession, in favour, not of William and Mary, but of Shaftesbury's puppet, the bastard Monmouth. That monstrous proposal gave Charles II. his chance, and in October 'Little Sincerity' (as he had nicknamed Shaftesbury) received his congé; and Shaftesbury from that time onward was driven into extremer opposition, indicting James as a recusant (1680), and bringing armed followers to the Oxford parliament (1681). In the July of that year he was again sent to the Tower, on a charge this time of high-treason, and though the Middlesex Whig grand jury threw out the bill in November, and he was consequently released, arrest was again impending, with no such chance of escape. Monmouth and Russell hung back from the open rebellion to which he promised to furnish 'ten thousand brisk City boys,' and, after some weeks' hiding, he fled to Holland early in December 1682. 'Delenda est Carthago' he had quoted against the republic ten years before; 'Carthago nondum deleta' greeted him now when he landed. On 22d January 1683 the 'fiery spirit' passed away at Amsterdam, whence the 'pigmy body' was borne home for burial in the place that had given him birth.

Transcendently clever, eloquent, and winning, fairly void too of lust and venality when most men were lustful and venal, Shaftesbury yet stands condemned by the many talents committed to him. He, who might have done so much good, did so little but what was evil. Whether for or against monarchy, for or against republicanism, for or against France, for or against Holland, he was always for himself—self the dominant principle to which alone he was true. At least, if that count for praise, he was the author of party government, ever ready to make capital out of religious animosities, 'atrocities,' perjuries, forgeries, anything. After all that has been written, men seem in doubt still whether Shaftesbury was the 'pure,' 'high-minded,' and 'great statesman' that Mr Christie would make him, or, what Charles pronounced him, 'the wickedest dog in England.' ('I believe, Sir, I am, of a subject'—one remembers his witty rejoinder.) Whether, again, was he a deist; and here again we have the well-known story, how one day he said to a friend, 'Men of sense are all of one religion.' 'And what religion is that?' a lady broke in; to whom, turning and bowing, he answered, '*That*, madam, men of sense never tell.'

See Dryden's *Absalom and Achitophel* and *Medal* (1681); part iii. of Butler's *Hudibras* (1678); the hostile *History* of Burnet, who is the chief authority for Shaftesbury's 'dotage of astrology;' the able apologetic *Life* by W. D. Christie (2 vols. 1871); the shorter, less partial study by Mr H. D. Traill in the 'English Worthies' series (1886); the article by Mr Osmond Airy in vol. xii. of the *Dictionary of National Biography* (1887); and other works cited at LOCKE and CHARLES II.

ANTHONY ASHLEY COOPER, third Earl of Shaftesbury, philosopher, was born at Exeter House, London, February 26, 1671, the grandson of the above, and son of that 'shapeless lump,' the second earl (1652–99), by Lady Dorothy Manners, daughter of the Earl of Rutland. Locke superintended his education at Clapham under a learned governess, Mistress Elizabeth Birch, who taught him to speak Greek and Latin fluently; three years at Winchester (1683–86) were not happy ones, for his schoolfellows visited on him the sins of his grandfather. With a tutor and two other lads he then travelled for three years more in Italy, Germany, and France, and on his return applied himself to study. A zealous Whig, he sat for Poole (1695–98), but ill-health compelled him to turn from politics to literature; and there is little to record in his life beyond two visits of a twelvemonth each to Holland (1698–99, 1703–4), where he lived with the Quaker, Benjamin Furly, and formed friendships with Bayle and Le Clerc; his accession to the earldom (1699); his marriage (1709) to Miss Jane Ewer of Lee, for 'the satisfaction of his friends,' but to his own subsequent contentment; his removal to Naples (1711); and his death there on February 15 (4 o.s.), 1713.

His somewhat superfine writings (Lamb hits off their style as 'genteel') were all, with a single exception, published after 1708, and were mostly collected as *Characteristics of Men, Manners, Opinions, Times* (3 vols. 1711; 2d enlarged ed. 1714). Here the 'moral realist' expounds his system, which Pope has immortalised in the *Essay on Man*, and which Mr Hunt reduces to the three main contentions, that ridicule is the test of truth, that man possesses a moral sense, and that everything in the world is for the best. An opponent of Locke, and a disciple of the 'Cambridge Platonists,' Shaftesbury found a follower in Hutcheson (q.v.), the founder of the Scottish school of philosophy. Still, like most prophets, he has had least honour in his own country, for, while there he was more attacked as a deist than praised as a philosopher, on the Continent he has attracted the attention, and generally the admiring attention, of thinkers like Leibnitz, Voltaire (who, however, ridicules his optimism in *Candide*), Lessing, Diderot, Mendelssohn, and Herder.

See Professor Fowler's *Shaftesbury and Hutcheson* ('English Philosophers' series, 1882); Hunt's *Religious Thought in England* (1870–73; new ed. 1884); Leslie Stephen's *English Thought in the Eighteenth Century* (1876); and two German monographs by Spicker (Freiburg, 1872) and Gizycki (Leip. 1875).

ANTHONY ASHLEY COOPER, seventh Earl of Shaftesbury, was born in London, 28th April 1801. From the early training of a faithful old servant, Maria Millis, the future philanthropist received his earliest and deepest religious impressions. He went to Harrow in his twelfth year, and to Christ Church, Oxford, in 1819, and took a first-class in classics in 1822, his M.A. degree in 1832; and he was made D.C.L. in 1841. As Lord Ashley he represented Woodstock in parliament from 1826 to 1830; and joining the Conservatives, then led by Lord Liverpool and Canning, he formed a close friendship with the Duke of Wellington, under whom he obtained the post of Commissioner of the India Board of Control (1828). Under Peel he was made a Lord of the Admiralty in 1834. In 1830 he married Emily, daughter of the fifth Earl Cowper (so that he was thus a connection by marriage of Lord Palmerston); by her he had six sons and four daughters. He represented Dorchester (1830-31), Dorset (1833-46), and Bath from 1847 to 1851, when he succeeded his father as earl. Among his earliest efforts at philanthropic reform was the promotion of two bills for the Regulation of Lunatic Asylums and for the better Treatment of Lunatics (1845), which have been called the Magna Charta of the liberties of the insane. He acted as chairman of the Lunacy Commission from 1828 till his death, a period of fifty-seven years. He took much interest in the passing of an act (1840) to prevent the employment of boy chimney-sweeps. He worked unweariedly for fourteen years on behalf of a bill limiting the hours of labour of women and young persons to ten hours a day, but it was 1847 ere a Ten Hours' Bill was passed, when it so happened he was out of parliament. He would not join Sir R. Peel's administration in 1841, because that statesman refused to countenance the Ten Hours' Bill; but in 1846 he supported Peel in his proposal to repeal the Corn Laws, an action which cost him his seat for Dorsetshire. A speech in connection with his Mines and Collieries Bill (1842) was considered his greatest effort. In 1842 was passed an act for abolishing the apprenticeship in mines, and excluding women and boys under thirteen from working underground; a Print-works Act was passed in 1845; and he was chairman of the Commission of Inquiry which resulted in the passing of the Factory Acts Extension Act (1867) and the Workshop Regulation Act (1867; consolidated 1878). In 1843 he joined the Ragged School movement. Relinquishing society and all amusements, he gave the remainder of his life to other beneficent schemes, and his time and strength were exhausted by letters, interviews, chairmanships, and speeches. To mention all the religious and benevolent societies in which he was interested would be to name the most prominent and useful agencies for good of the present day. Peabody's scheme for bettering the house accommodation of industrial London sprang from Shaftesbury's efforts in the same direction. He was the adviser of Lord Palmerston in many important church appointments, and was consulted by the Queen and Prince Consort. The freedom of Edinburgh was conferred upon him in 1878, and of London in 1884. Active and vigorous to the last, he died at Folkestone, October 1, 1885. Although not a great orator, he spoke with neatness, force, and precision. In religious matters he was an out-and-out evangelical, and strenuously opposed ritualism, rationalism, and socialism when divorced from Christianity.

See his *Speeches*, with introduction by himself (1868), and Hodder's *Life and Work of the Earl of Shaftesbury* (3 vols. 1886).

Shag. See CORMORANT.

Shagreen. This term is applied to the skins of sharks, rays, and other fish included in the order Selachia, whether they are artificially prepared or not. These skins are furnished with a covering of small nodules or grains of dentine, which is of a hard nature and resists wear of the surface better than ordinary leather. In the shagreen used by cabinet-makers for smoothing wood, the grains or papillæ are sharp-pointed and closely set, but in the case of the skins of allied species these grains are comparatively flat and of different outlines. Such skins, when prepared like parchment, dyed and smoothed, present an attractive appearance, and are used for covering small caskets, boxes, cigar cases, spectacle cases, and similar articles. Shagreen was formerly a good deal employed for covering also watch cases, instrument cases, &c. The name shagreen (Persian *sâghri*, meaning the back of a beast of burden) is also, and perhaps was originally, applied to the skins or to portions of the skins of horses, asses, and other animals prepared by unhairing and scraping them. Each piece is then stretched on a frame, and while they are still moist the seeds of a species of Chenopodium are sprinkled on the surface and forced in by means of the feet or of a press. The skin is then left to dry, and when the seeds are beaten out it has a pitted appearance. It is next pared down with a knife nearly to the bottom of these depressions, after which it is macerated in water till the pits swell and give the skin a pimpled appearance resembling that of a shark. A steeping in a warm solution of soda and afterwards in brine completes the dressing, and it can then be dyed. The covers of old Persian manuscripts are made of this shagreen, which is also used for horse-trappings and shoes in the East. Wood has been embossed by a process somewhat similar to the way leather shagreen is made. See EMBOSSING.

Shâh (Persian, 'king,' 'monarch,' 'prince'), the general title of the supreme ruler in Persia, Afghanistan, and other countries of southern and central Asia. The sovereign, however, may, and outside of Persia frequently does, decline the title, assuming in its place that of Khân (q.v.), an inferior and more common appellation. The same title can also be assumed by the shah's sons, and upon all the princes of the blood the cognomen Shâh-zâda ('king's son') is bestowed.—For Shahpur, see PERSIA, Vol. VIII. p. 67; for Shah Soojah, see AFGHANISTAN.

Shahabad, a town of Oude, 80 miles NW. of Lucknow by rail, with a pop. of 18,510—only a third of what it was in the 16th century. In 1868 there was a savage riot here between Hindus and Mussulmans at the Moharram festival.

Shahjahanpur, a town of British India, in the North-west Provinces, stands 100 miles by rail NW. from Lucknow. It take its name from Shah-Jehan, in whose reign it was founded in 1647. It was a hot-bed of rebellion during the Mutiny of 1857-58. Sugar is made and exported. Pop. (1890) 77,690.—The *district* has an area of 1745 sq. m. and a pop. of 856,946.

Shah-Jehan, the fifth of the Mogul emperors of Delhi, was during his father's reign employed in military expeditions against the Rajputs, the independent Mohammedan states of the Deccan, and the Afghan tribes around Kandahar. From 1623 he was in revolt against the Emperor Jahangir, his father, and was still unreconciled at the latter's death in 1627, when he was at once saluted as emperor by the nobles. The chief events of his reign were the war against the Deccan sovereigns, which resulted in the complete destruction of the kingdom of Ahmadnagar (1636), and the subjugation (1636) of those of Bijapur and Golconda; an indecisive contest against the Uzbeks of Balkh (1645-47); attempts to recover Kandahar from the Persians (1637, 1647-53), which, however, was finally lost; and a second successful war, conducted by his son Aurungzebe, against the Deccan princes (1655). But in 1658 the emperor fell dangerously ill, and his sons commenced to dispute regarding the succession. Ultimately Shah-Jehan was taken prisoner by Aurungzebe, and confined in the citadel of Agra till his death, December 1666. This emperor administered strict justice, and was an able and capable ruler, and a clever financier. The magnificence of his court was unequalled; the splendid 'peacock throne' was constructed by his orders at a cost of nearly £7,000,000, and many magnificent public buildings executed under his direction remain as monuments of his greatness. Chief of these are the superb Taj Mahal and the lovely 'pearl mosque' at Agra (q.v.), and the palace and great mosque at Delhi (q.v.).

Shah Nameh. See Firdausí.

Shaikh-Othman. See Aden, and Falconer (Ion Keith).

Shairp, John Campbell, one of the Shairps of Houston, Linlithgowshire, was born 30th July 1819. He was educated at the Edinburgh Academy and Glasgow University, whence he went as Snell Exhibitioner to Oxford. There he gained the Newdigate prize for an English poem upon Charles XII., and graduated with second-class honours in 1844. From 1846 to 1857 he was a master at Rugby. From Rugby he went to St Andrews as deputy-professor of Latin. In 1861 he succeeded to the Latin chair, and in 1868, upon the death of Forbes, to the principalship of the United College. In 1877 he was appointed professor of Poetry at Oxford, and reappointed in 1882. He died 18th September 1885.

Shairp was an ideal Scotsman, but with a strong appreciation of English life and thought. His patriotism was almost phenomenal. A summer spent out of Scotland he considered wasted. He explored its loneliest spots and revelled in all its historical associations. The haunts of Jacobites and of Covenanters alike fascinated him, and there are few better companions in the Borderland and the Highlands than his sketches and poems.

His character and thought were moulded by home surroundings, by love of nature and of Wordsworth (his favourite author), by life at Oxford, and by Coleridge, Scott, Keble, Newman, and Erskine of Linlathen. He found the routine work of teaching somewhat irksome, but as a professor he was suggestive, stimulating, and sympathetic. Few have enjoyed the friendship and esteem of so many distinguished men. His singularly lovable and transparent nature, his sense of duty and loftiness of aim, and his sterling unobtrusive Christian principles impressed such men as Norman Macleod, Clough, Matthew Arnold, Lord Coleridge, Archbishop Benson, Professor Veitch, Dr John Brown, and Dean Stanley more than all his writings. It is by these, however, that his name will live. They reveal rare poetic instincts and a keen, though kindly, critical faculty. They aim at promoting high thoughts, at quickening love of nature, at increasing interest in history, literature, and philosophy, and at suggesting at least clues to some of the deeper mysteries of life and religion. His own interest in these subjects is healthily infectious. His prose is clear, simple, and vigorous; his poetry fresh and natural, with a true ring in the lowland Scotch.

His principal works are *Kilmahoe* (1864), *Studies in Poetry and Philosophy* (1868), *Culture and Religion* (1870), *The Poetic Interpretation of Nature* (1877), *Burns* (1879), *Aspects of Poetry* (1881), *Glen Desseray* (1886), and *Sketches in History and Poetry* (1887). See Prof. Knight's *Principal Shairp and his Friends* (1888).

Copyright 1892 in U S. by J. B. Lippincott Company.

Shakers, the popular name first applied in derision to 'The United Society of Believers in Christ's Second Appearing,' a small religious sect which had its origin in England about the middle of the 18th century. The first leaders of this sect were James Wardlaw, a tailor, and Jane, his wife, the latter claiming to have special spiritual illumination, and to have 'received a call' to go forth and testify for the truth; she proclaimed that the end of all things was at hand, that Christ was coming to reign upon the earth, and that his second appearance would be in the form of a woman, as prefigured in the Psalms. She still adhered to many of the tenets of the Society of Friends, of which she and her husband were members, and preached against war, slavery, profane swearing, and the taking of the legal oath. Among her followers was one Ann Lee, an uneducated girl of poor parentage, of a highly nervous organisation, a strong will, and ambitiously fond of power, who, professing to have received a spiritual baptism, with a command to go forth and preach this new gospel, began to preach in Toad Lane and the adjacent streets of Manchester. She acquired great power over her hearers, who believed in her as one filled with the Holy Ghost, and speaking with the voice of God. The preaching in the streets, accompanied with shouting, speaking of tongues, and other physical manifestations, excited much public hostility, in consequence of which James and Jane Wardlaw, Ann Lee, and her parents were fined and imprisoned in the Old Bailey Prison in Manchester upon a charge of obstructing the streets and violating the Sabbath. A professed experience of Ann Lee while in prison, in which the Lord Jesus appeared before her and became one with her in form and person, led her to be recognised by Jane Wardlaw and her followers as the female Christ—the Bride of the Lamb—in whose person Christ had come to reign upon the earth. She was henceforth styled 'Mother Ann,' and has since been recognised as the 'Head' of this new order. Her claim to be the female Christ excited only ridicule among her neighbours; hence another special revelation—that the foundations of Christ's kingdom were to be laid in America. In the following year, accompanied by her husband and five of the most prominent members of the society—four men and one woman—she emigrated to America, and settled at Niskayuna, 7 miles from Albany, New York, now Watervliet, distinguished as the parent Shaker settlement in America. Here, in their wilderness home, 'Mother Ann' established absolute community of property, the sacred duty of labour, and enforced upon her followers celibacy, which she had previously taught as becoming to 'Believers,' teaching them that no form of love could be allowed in the Redeemer's kingdom, and that men called into grace must live as the angels, with whom 'there is no marrying nor giving in marriage.' Her husband, Mr Stanley, a blacksmith, to whom she had been married in early life, and by whom she had had four children, all of whom had died in infancy, now left her; but believing herself the 'Bride of the Lamb,' she was not daunted either in purpose or faith.

Early in 1780 Joseph Meacham, a Baptist preacher, and Lucy Wright were sent from New Lebanon to Niskayuna, to seek new light as to the way of salvation. They had both been greatly exercised in the religious revival, accompanied by physical manifestations not understood by the clergy, which had occurred the previous year in Albany and adjacent districts, and now, satisfied that in this new order they had found the key to their religious experiences, became believers in Ann Lee. The first converts to Shakerism in America, they returned home and founded a Shaker settlement at New Lebanon which still exists. The denunciations of Ann Lee against war, and her refusal to take the colonial oath, caused her to be suspected as a British spy, and as such she was for several months imprisoned at Poughkeepsie. In the spring of 1781 she started upon a missionary tour throughout the colonies, which she continued until the autumn of 1783, making a goodly number of converts and laying the foundation of future Shaker settlements. In the autumn of 1784 she died at Watervliet, having previously made over the 'headship' of the society to Joseph Meacham and Lucy Wright as representatives of the dual rule of

God, through the male and female Christ, conferring upon Lucy Wright the title of 'Mother Lucy.' Her death was a great shock to her followers, many of whom believed that she was to live in the physical form for ever upon the earth among her people. Her successors, however, taught them that like the male Christ she had cast off her dress of flesh, and withdrawn from worldly sight, but still lived among her people, visible to eyes exalted by the gift of spiritual sight So all the saints would remain after death near and be in 'union' with the visible body of Believers, becoming their spiritual teachers. This was accepted as a new and divine revelation, and still is a vital part of the Shaker religion. Under the ministrations of Joseph Meacham and Lucy Wright ten Shaker settlements were formed and an organisation of these settlements effected, bound together by a covenant, recognising the duality of God, the divine mission of Ann Lee as the female Christ, the sacred duty of celibacy, labour, and community of property, and appointing elders and deacons of both sexes for the government of their temporal and spiritual affairs. Joseph Meacham died in 1796, after which for twenty-five years, and until her death, 'Mother Lucy' ruled as the sole head of this new order, discontinuing the title of 'Mother' for the female head of the order at her death, and appointing a successor with the title of 'Elderess,' which title is still given to the female head of the church.

According to the 1890 census there are fifteen Shaker settlements in the United States, three each in Massachusetts and Ohio, two each in New York, New Hampshire, Maine, and Kentucky, and one in Connecticut. They have ten edifices, valued at $36,800, with a seating capacity of 5650. There are 1728 members, a reduction of nearly one-third since 1870. The value of their communistic property is about ten millions. They are the oldest communistic order in the United States, and by their success demonstrate the possibility—for a time at least—of communistic life. They have two classes of members—the 'Probationers' and 'Covenantors;' the former practically adopt the Shaker doctrines, but retain control over their own property, or, if they have given it to the community, may at any time resume control of it without interest; the latter consecrate themselves and their property to the society, never to be reclaimed by them or their legal heirs. All full members have equal rights in the community, without regard to the property consecrated, only that it is their all. Each Shaker settlement is divided into families, each family consisting of brothers and sisters, who live in the same house, sit upon opposite sides of the same table, and are presided over by an elder and elderess, their temporalities being superintended by a deacon and deaconess. They take their meals in silence, are scrupulously neat, live well but simply, *employ no doctors, take no drugs*, and are noted for their good gardens, flower-seeds, and medicinal herbs which they cultivate for the market. Their numbers are recruited mostly by young men and women, although occasionally married people with their children join the order. Believing that education is the right of all, they provide liberally for the education of the children left in their care. Their worship consists of vocal and instrumental music, 'dancing and making merry' followed by silent communion, and sermons which in point of devoutness, logic, and rhetorical form may fairly be compared with the sermons of the ordinary Christian churches. Their societies are united in one organisation presided over by the head elderess, assisted by the chief elder. They repudiate a priesthood, monarchy, and paid ministry, and teach that it is not Christ or Ann Lee, but the principles of Christ which must be accepted, and that all may become Christ's by death of the generative nature and an infusion of the Christ spirit. They repudiate the atonement by blood and the resurrection of the body as 'a horrid idea,' anti-Christian and anti scientific. They have no creed, but depend upon divine revelation, which they claim is progressive according to the needs and development of humanity. They believe that God is dual—the Eternal Father and the Eternal Mother—the heavenly parents of all beings angelic and human: that the first revelation of God to humanity was as a Great Spirit pervading all things, hence pantheistic worship: that the second revelation of God was as Jehovah; the third through Jesus, a divinely inspired man, representing God as a father; and that in 1770, the beginning of the last cycle, God was revealed in the character of the Eternal Mother—the bearing spirit of all the creation of God in divine love and tenderness—in the person of Ann Lee as the female Christ. Salvation, they teach, can only come by the death of the Adamic or generative life, by which man becomes a new order of being, able to comprehend 'the mysteries of God.' The earthly procreative relation for the purposes of reproduction is fit only for the children of this world, and carnal sexual indulgence is denounced as 'the unfruitful works of darkness.' Labour is 'a sacred and priestly duty,' and the work of the saints is by loving labour bestowed upon the earth to redeem it from the Adamic curse, which was lifted by the coming of Christ; each child born has a title-deed from God for land sufficient for its existence, and in the present advanced stage of civilisation this right is best recognised by a community of interest in the rent obtained for advantages of location, fertility, and mineral wealth. They denounce war, claiming that all disputes of individuals and nations should be settled by arbitration. They oppose the union of church and state, take no interest in governments as now constituted, loving their own country only as the favoured land of God, believing that in America the millennium is first to come when human governments, civil and ecclesiastical, will recognise the female element in harmony with the dual government of God. They make no effort to secure converts, it being a part of their religion that God will designate whom he has called to live in 'union,' and claim that instead of Shakers becoming extinct as is prophesied, and as they admit is prophetically indicated by their loss of membership, 'the first heavens and earth are passing away, and that a new heavens and new earth will be evolved out of the chaotic elements which exist in church and state humanity by the inspiration of revelation from the Christ heavens'—in other words, that the general principles of Shakerism will be established throughout the world.

English Shakers was the name commonly given to a community calling themselves '*Children of God*,' founded by Mary Anne Girling (born 1827), who about 1864 came to believe that she was a new and final incarnation of God, and insisting on celibacy. Founded in London, the communion grew to about 150 members, and in 1872 settled on a property purchased for them, New Forest Lodge, in the New Forest, Hampshire. Though industrious and blameless, they sank into poverty; and, unable to pay their debts, were evicted in December 1873, and subsequently, shrunk to twenty or thirty in number, lived a miserable existence in sheds and temporary shelters. Mrs Girling, who was confident she would never die, did die of cancer, 18th September 1886, and her sect collapsed.

See Elder F. W. Evans, *The Shakers* (New York, 1859), his *Autobiography of a Shaker* (1879), the Shaker magazine; also Eads, *Shaker Sermons* (1879).

Shakespeare, WILLIAM, the greatest of dramatic poets, was born at Stratford-on-Avon towards the close of April 1564. The birthday is uncertain; tradition points to April 23, O.S., corresponding to our 5th May; on April 26 the infant was baptised. The house in Henley Street which is believed to be the birthplace may still be seen—as restored. The child's father, John Shakespeare, son of Richard Shakespeare, a Warwickshire farmer, was a fell-monger and glover, perhaps also a butcher, and certainly a dealer at times in corn and timber. In 1557 he married Mary Arden, daughter of a wealthy farmer, who on dying had left her a small estate named Asbies, with the reversion to part of another property at Snitterfield. John Shakespeare for a time prospered; in 1561 he became chamberlain of the borough, afterwards an alderman, and in 1568 high-bailiff of Stratford. The boy William was John Shakespeare's third child; two daughters born before him died in infancy. The later born children were five—two daughters, of whom one outlived the dramatist, and three sons, Gilbert, Richard, and Edmund; the last of these became an actor and died in 1607.

Although John Shakespeare was a respected burgess of Stratford, his education was small; he could not write his name. In all probability his eldest son was educated at the free school of Stratford, where beside English he would learn something of Latin, possibly even the elements of Greek. 'Small Latin and less Greek' is Ben Jonson's description of the scholarship of his great contemporary. The Greek, if any, must have been small indeed. At a later time Shakespeare seems to have acquired a little French, and possibly something of Italian. As a boy he may have seen dramatic entertainments at Stratford, for companies visited the town and performed there on several occasions from the year of his father's bailiffship onwards. In 1575 Leicester received Queen Elizabeth at Kenilworth, and it is possible that John Shakespeare may have taken his eldest son to look at the masques and mummeries; Oberon's description of the 'mermaid on a dolphin's back' (*Midsummer Night's Dream*, II. i. 148-168) has been supposed to be a reminiscence of the occasion. In 1578 the fortunes of John Shakespeare underwent an unfavourable change, and for many years pecuniary troubles pressed upon him; he mortgaged the Asbies estate, and sold his wife's reversionary interests at Snitterfield; he ceased to attend the town-council; his taxes were remitted; as late as 1592 it is reported of him that he did not attend church for fear of 'processe for debt.' At what date he removed his son from school we cannot tell. Perhaps, as one tradition has it, the boy was apprenticed to a butcher; perhaps he was for a time an attorney's clerk—a conjecture founded on certain supposed allusions of his dramatic contemporary Nash, and on the fact that the legal references in Shakespeare's plays and poems are very numerous and give evidence of information which is remarkably correct. The blank in our knowledge of this period of his life is thus filled with guesses—guesses not altogether unprofitable. The worldly prudence of Shakespeare's manhood may have come to him as the lesson of these early years of trouble in his father's house. But the lesson of prudence was not learned all at once. A bond given previous to marriage between William Shakespeare and Anne Hathaway, dated November 28, 1582, was found in 1836 in the registry of Worcester. The marriage was to take place after the banns had been once asked. Anne Hathaway was the daughter of a substantial yeoman, lately dead, of Shottery in the parish of Stratford; she was eight years older than the bridegroom, who was only in his nineteenth year; she was socially his inferior, and it is probable that she was uneducated. The marriage may have been pressed forward by Anne's friends in order that a child—Shakespeare's eldest daughter, Susanna (baptised May 26, 1583)—might be born in lawful wedlock. Mr Halliwell-Phillipps argues that the bond was not improbably preceded by a contract, which, according to the customs of the time, would have given the contracting parties the mutual rights of husband and wife, though as yet unsanctioned by the church. The marriage was doubtless solemnised soon after the date of the bond, but where and on what day is unknown. Two years after the birth of Susanna twins were born, Hamnet and Judith (baptised February 2, 1585). These three were Shakespeare's only children. Hamnet (probably named after a Stratford friend and neighbour, Hamnet Sadler) died in his twelfth year (buried August 11, 1596); both daughters survived their father.

Three or four years, as it is believed, after his marriage Shakespeare quitted his native town. 'He had,' says his first biographer, Rowe, 'by a misfortune, common enough to young fellows, fallen into ill company, and, amongst them, some that made a frequent practice of deer-stealing engaged him more than once in robbing a park that belonged to Sir Thomas Lucy, of Charlecote, near Stratford. For this he was prosecuted by that gentleman, as he thought, somewhat too severely; and, in order to revenge that ill-usage, he made a ballad upon him. And though this, probably the first essay of his poetry, be lost, yet it is said to have been so very bitter that it redoubled the prosecution against him to that degree that he was obliged to leave his business and family in Warwickshire for some time, and shelter himself in London.' It seems likely that in essentials the story thus reported by Rowe is true, and a verse of the ballad—whether genuine or written, as is more likely, to suit the story—has been given by Oldys. In *The Merry Wives of Windsor* Justice Shallow complains of Falstaff's having killed his deer; there are 'luces' in the Shallow coat-of-arms as in that of the Lucy family, which luces in the Welsh parson's pronunciation become 'louses'—a play on words occurring also in the alleged stanza of Shakespeare's offensive ballad.

A tradition, which appears to have come down from Betterton and D'Avenant, relates that Shakespeare's first employment in London was that of holding at the playhouse door the horses of those gentlemen who rode to the theatre unattended by servants. 'In this office,' so Johnson received the tale from Pope, 'he became so conspicuous for his care and readiness that in a short time every man as he alighted called for Will Shakespeare, and scarcely any other waiter was trusted with a horse while Will Shakespeare could be had;' by-and-by he hired boys to wait under his superintendence, and 'Shakespeare's Boys' continued to be their name long after their master had risen to higher employment. Mr Halliwell-Phillipps holds that the story need not be set aside as an absolute fiction. The date of Shakespeare's flight to London can hardly have been earlier than 1585, and it is not likely to have been later than 1587. Mr Fleay conjectures that in the last-named year he joined Lord Leicester's players during their visit to Stratford, or soon after that visit; but tradition lends no support to the supposition that Shakespeare left his home with a view to trying his fortune on the stage. Except that we find his name joined with that of his father in an attempt made in 1587 to assign the Asbies property to the mortgagee, we know nothing for certain of Shakespeare's life from the date of his twin-children's birth until the year 1592, when he was an actor and a rising playwright. The dramatist Robert Greene, dying in that year, addressed three of his brother-authors, Marlowe, Peele, and Nash or Lodge, in a passage of his pamphlet, *Greene's Groatsworth of Wit bought with a Million of Repentance*, warning them against the ungrateful and inconstant race of players: 'Yes, trust them not: for there is an upstart crow, beautified with our feathers, that with his *Tygers heart wrapt in a players hide* supposes he is as well able to bumbast out a blanke verse as the best of you: and being an absolute *Johannes factotum*, is in his own conceit the only Shake-scene in a country.' The line of verse here parodied,

Oh, tiger's heart wrapt in a woman's hide,

occurs in the *Third Part of Henry VI.* and in the old play, *Richard Duke of York*, on which it is founded. Greene suggests that Shakespeare has been pilfering from a play in which he and Marlowe had each a hand. The editor of Greene's pamphlet, Henry Chettle, soon after, in his pamphlet *Kind-Harts Dream* (December 1592), made a handsome apology to Shakespeare: 'I am as sory as if the originall fault had been my faulte, because my selfe have seene his [Shakespeare's] demeanor no lesse civill than he exclent in the qualitie he professes; besides, divers of worship have reported his uprightnes of dealing, which argues his honesty, and his facetious grace in writting, that aprooves his art.' From these references we infer that Shakespeare had already made himself a valuable member of his dramatic company, that he was already known as a writer for the stage, that his merit as an actor ('quality' having special reference to this) was not inconsiderable, and that as a man he was honourable in all his acts. High eminence as an actor Shakespeare did not attain, though it appears from Hamlet's advice to the players that he had a just perception of the actor's merits and defects. Rowe assures us that 'the top of his performance was the ghost in his own *Hamlet*.' It is believed that he took the part of Old Knowell in Jonson's *Every Man in his Humour*, and perhaps that of the venerable Adam in *As You Like It*.

In 1593 appeared Shakespeare's first published work, the narrative poem, written in a six-line stanza, *Venus and Adonis*. It is dedicated to the young Earl of Southampton, the poet's patron and friend, who, according to a tradition derived from D'Avenant, on one occasion proved his friendship by a large gift of money to enable Shakespeare 'to go through with a purchase he had a mind to.' *Venus and Adonis* is described by its author as 'the first heir of his invention;' it is an elaborate piece of Renaissance paganism, setting forth ideals of sensuous beauty, male and female, in the persons of the amorous goddess and of the young hunter, whose coldness meets and foils her passion. Close observation of nature and much sweetness of versification characterise the poem; the passages of dialogue are, as it were, studies in the casuistry of passion; elaborate conceits, such as few Elizabethan poets could escape from, abound. The dedication promises a 'graver labour,' and this soon followed in the *Lucrece* (published 1594). The theme of the *Venus* is here, as it were, reversed; the lawless passion of Tarquin is confronted by the ardent chastity of the Roman wife. The stanza is one of seven lines; the dedication is again to Southampton, and its words express strong and deep devotion. Both the *Venus* and the *Lucrece* became immediately popular, and were many times reprinted.

Shakespeare's earliest dramatic exercises consisted probably in adapting to the stage plays by other authors which had grown a little out of date. Many critics have pointed to *Titus Andronicus* as an example of such work, and a tradition put on record in 1687 confirms this view. The play certainly belongs to a moment in the history of English tragedy which we may describe as pre-Shakespearian; it reeks with blood; its effects are rather those of horror than of dramatic terror and pity; if Shakespeare wrote it we must believe that he wrote it before his genius had discovered its true direction. Another of the early plays in which Shakespeare probably worked upon older material is the *First Part of Henry VI.*; some critics have held that in its construction three hands can be distinguished. However this may be, we accept it as all but certain that the play contains pre-Shakespearian work; we are pleased to think that the ignoble portraiture of Joan of Arc is not of our great dramatist's conceiving; in the Temple-garden scene (ii. 4), which tells of the plucking of the white rose and the red, we have perhaps Shakespeare's chief contribution to this drama.

We dare not say for certain at what precise date Shakespeare's career as a dramatic author began; but 1589-90 cannot be far astray. Among his earliest experiments in comedy were *Love's Labour's Lost*, *The Comedy of Errors*, and *The Two Gentlemen of Verona*; among the earliest historical dramas were the second and third parts of *Henry VI.*, *King Richard III.*, and *King Richard II.*; the first romantic tragedy (setting aside *Titus Andronicus*) was undoubtedly *Romeo and Juliet*. The evidence by which the chronology of Shakespeare's several works is ascertained or inferred with more or less probability is of various kinds, including entries of publication or intended publication in the Stationers' Registers; statements about the plays and poems, or allusions to them, or quotations from them by contemporary writers in works of known dates; facts connected with the history of dramatic companies which presented plays of Shakespeare; allusions in the plays to historical events, and quotations by Shakespeare from publications of the day. We cannot fail also to observe the growth of Shakespeare's imaginative power, his intellectual reach, his moral depth, his spiritual wisdom; with respect to each of these we must needs recognise a profound difference between the earlier and the later plays. At the same time we perceive a gradual change, or rather a group of changes, taking place in the structure of his dramatic verse. In his verse of early date the sense closes with the line far more frequently than is the case in his verse of a later period, and with this growing tendency to carry the sense beyond the line arises also an inclination or a readiness to place as the final word of the line some word such as *am*, *do*, *I* ('light ending'), or even such as *and*, *of*, *if* ('weak ending'), which precipitates the reader or pronouncer of the passage into the next following line. Thus in its structure the versification becomes more varied and freer, or, if not freer, subject to subtler and less obvious laws. It is part of the same process that Shakespeare gradually ceased from employing rhyme for dramatic purposes, and again that he allowed the decasyllabic line to pass much more frequently into one of eleven syllables ('double ending' or 'feminine ending'). These peculiarities of versification admit of statistical calculations in their process of development, and have formed the subject of much careful study among recent Shakespearian scholars.

In his early comedies Shakespeare is trying, as it were, his 'prentice hand in various experiments. *Love's Labour's Lost* (*c.* 1590) is perhaps his first original play; no source is known; some of the leading characters seem to be named after persons of note in recent or contemporary French history. Learned pedantry, fantastical extravagance of speech, the affectations of amorous poetry are satirised, and the dramatist pleads against artificial restraints on conduct and pseudo-ideals and in favour of nature and healthy passion. The play was partly rewritten about 1598, when it was presented before Queen Elizabeth. *The Comedy of Errors* (c. 1591) is a lively tangle of farcical incidents; it is founded on the *Menæchmi* of Plautus, which was translated into English by Warner, but Shakespeare seems to have reached the *Menæchmi* either in the original or through some other rendering. The twin-brothers Dromio are an addition to the twin-brothers of the Latin comedy, and heighten the laughable perplexities of the play. A serious—almost a pathetic—background to the story is invented by Shakespeare, and in his Luciana we get a hint of some of his later beautiful creations of female character. *The Two Gentlemen of Verona* (c. 1592), a romantic love comedy, exhibits a marked advance in the presentation of character, though not in the construction of plot. There is apparently a connection between the story of the play and the story of the 'Shepherdess Felismena' in the *Diana* of George of Montemayor, a Spanish piece of Arcadian romance. Shakespeare's humour breaks forth in his portrait of the clown, Launce; Julia is the first of his charming feminine disguisers in male costume. This group of early comedies may be considered to close with *A Midsummer Night's Dream* (c. 1593-94). Hints for the play may have been taken from Chaucer, from Plutarch, from the *Diana*, and from popular superstitions; but it is essentially a new creation of the poet. No other comedy of Shakespeare has so large a lyrical element; the figures of the lovers are faintly drawn, but the exquisite fairy-poetry, and the humours of sweet bully Bottom make sufficient amends.

Meanwhile Shakespeare was also engaged on the English historical drama. In the *Second and Third Parts of Henry VI.* (c. 1592) he worked upon the basis of old plays written probably by Marlowe and Greene—possibly also Peele—and in the revision he may have had Marlowe as a collaborator. To come under the influence of that great master, Christopher Marlowe, was no disadvantage for one who could accept gains from every quarter and by the force of his genius could make them his own. In *King Richard III.* (c. 1593) he still writes in Marlowe's manner, though the play is wholly his own. As with Marlowe the protagonist everywhere dominates over the secondary characters; as with Marlowe a great criminal is made of fascinating interest, by virtue of his unity of passion and of power. The chief source from which Shakespeare derived the material for his plays from English history was the chronicle of Holinshed. The three parts of *Henry VI.* and the tragedy of *Richard III.* present a continuous view of the rise and fall of the House of York. In *King Richard II.* (c. 1594) is set forth the rise of the House of Lancaster. Here, though there are reminiscences from *Edward II.*, the influence of Marlowe is no longer supreme. The contrast between the hectic, self-indulgent, rhetorical Richard, who yet possesses a certain regal charm, and his strong adversary Bolingbroke is a fine psychological study of a kind which is essentially Shakespearian and not Marlowesque. To mould into dramatic form the tough material of history was an admirable exercise in dramatic craftsmanship. The breadth and sanity of history also tended to preserve Shakespeare from the danger of romantic extravagance, such as injures the art of other dramatists who worked chiefly on stories of crime and passion supplied by Italian romance. *King John* (c. 1595) stands apart by its subject from both the York and the Lancaster series of plays; but in style it has something in common with *Richard II.* It is founded not so much on Holinshed as on an old play, *The Troublesome Raigne of King John*, and a comparison of his original, seen in its poverty, crudity, and coarseness, with Shakespeare's creation, where everything is ennobled, purified, and refined, affords a study of no little interest in dramatic art.

In the passage which describes Oberon's vision in *A Midsummer Night's Dream* a magnificent compliment to Queen Elizabeth, 'the imperial votaress,' is introduced. Shakespeare as a member of the Lord Chamberlain's company appeared on several occasions before her majesty. In December 1594 he acted in two comedies at Greenwich Palace. On Innocents' Day of the same year the *Comedy of Errors* was presented in the hall of Gray's Inn. The playhouse in which at first he ordinarily performed was either that known as 'The Theatre' or 'The Curtain' on the Shoreditch edge of London. From 1599 onwards he was connected with the new playhouse, 'The Globe,' which stood near London Bridge on the Southwark side, and here and in the Blackfriars Theatre (1596) his dramas were presented. His good sense and worldly prudence are remarkable; before long he became a theatrical shareholder, and had gathered sufficient wealth to purchase (1597) 'New Place,' a large house in his native town. In 1596 his father, moved perhaps by the wish of the dramatist to occupy a dignified position, applied for a grant of coat-armour, and sought, probably without success, to recover the mortgaged Asbies estate. The year was one of affliction, for in August Shakespeare's only son—Hamnet—died. Yet Stratford remained dear to the sorrowing father; he kept in close relation with his friends and former neighbours, and in 1598 was engaged in negotiating a loan for the corporation of the town. The runaway youth of ten or twelve years since was now a man of consideration and of substance. In September 1601 his father died; his mother lived until September 1608. In the year following his father's death Shakespeare bought for £320, then a large sum of money, 107 acres near Stratford, and enlarged the bounds of his New Place property. In 1605 he paid £440 for the unexpired term of the moiety of a lease of the tithes of Stratford, Old Stratford, Bishopton, and Welcombe. He did not despise small things, for we find him in 1604 proceeding for the recovery of a debt amounting to £1, 15s. 10d. With boundless empire in the realm of imagination he valued also at its real worth a foothold on this material earth of ours.

Among the earlier creations of his genius one stands apart from the rest—the tragedy of *Romeo and Juliet*. Possibly as we have it now the play is a revision dating about 1596-97 of a work written as early as 1592. It is founded in the main upon a poem, *Romeus and Juliet* (1562), by Arthur Brooke, which versifies the tale taken by the French Boisteau from the Italian of Bandello; but Shakespeare was also probably acquainted with Paynter's prose version of the story in his *Palace of Pleasure* (1567). The play has a lyrical sweetness, swiftness, and intensity such as we do not find elsewhere in its author's writings. It has many signs of early workmanship—much rhymed verse, and many conceits and over-strained ingenuities; but these last are forgotten in the high passions of joy and anguish which find expression in the tragedy. The brilliant Mercutio, the tranquil Friar, the humorous figure of the Nurse form an admirable background from which stand out the persons of the lovers—a youth and a maiden of the south possessed by one all-absorbing emotion. It is strange that Shakespeare did not follow up this early tragedy by any play of a like kind. Near to it in the chronological order probably stands the exquisite comedy of *The Merchant of Venice* (c. 1596), which occupies a middle place between the group of Shakespeare's earliest comedies and those which lie around the year 1600. The story of the caskets and the story of the pound of flesh had probably been brought together in an old play now lost which is mentioned by Stephen Gosson in 1579; but a play of that date can have afforded only rude material on which to work. The advance in characterisation from that of Shakespeare's previous comedies is remarkable; no earlier heroine is comparable with Portia, and the gracious brightness of her figure is admirably enforced by its contrast with the dark colours in which the Jew is painted. Something was doubtless derived from Marlowe's Jew of Malta, Barabas; but Shylock, with all his passion of revenge, is human; Barabas is an incredible monster of vices. Shakespeare's mastery of comedy aids him in the historical plays which followed the *First and Second Parts of King Henry IV.* (1597-98) and *King Henry V.* (1599). In these dramas the fortunes of the House of Lancaster are followed to their glorious culmination. The turbulent years from the battle of Homildon Hill (1402) to the death of the usurping Bolingbroke (1413) supply the material for the historical portion of both parts of *Henry IV.* But interwoven with the history is that inimitable comedy of which Falstaff is hero. In the epilogue to the second part a promise is given that Falstaff shall again appear in another play in which the author will continue the story and make the spectators 'merry with fair Katherine of France.' Shakespeare found it impossible to fulfil that promise. In the heroic drama of *King Henry V.* there is no place for the fat knight. The play is inspired by the ardent patriotism, the lofty national enthusiasm of the age of Elizabeth. In the person of the king Shakespeare presents his ideal of a noble ruler of men. The material for *Henry IV.* and *Henry V.* was derived partly from Holinshed, partly from an old play entitled *The Famous Victories of Henry V.* Thus, as it were, with a trumpet-note of patriotic pride and battle-ardour Shakespeare's historical plays of England are brought to a close.

There is a tradition dating from 1702 that Queen Elizabeth commanded Shakespeare to exhibit Falstaff in love, and that in obedience he hastily wrote—in fourteen days it is said—*The Merry Wives of Windsor* (1598-99). The comedy is of special interest as a picture of middle-class English life, and may be well studied in comparison with Jonson's *Every Man in his Humour;* but the fatuous Falstaff of the *Merry Wives* is far different from the ever-detected yet never-defeated Falstaff of the historical plays. The comedy is written almost wholly in prose, and in its incidents approaches farce. It may be that it was about this time that Shakespeare adapted and enlarged the old play, *The Taming of a Shrew*, or perhaps adapted and enlarged a previous adaptation of that play by another hand. In *The Taming of the Shrew* (1597?) Shakespeare's genius shows itself chiefly in connection with the boisterous heroine, her high-spirited tamer Petruchio, and the drunken tinker of the Induction. Conjectural attempts have been made to distinguish the scenes and lines which may be ascribed to Shakespeare; but these must be accepted with reserve. The same animal spirits and intellectual vivacity which characterise the *Merry Wives* and the *Shrew* appear—but now refined and exalted—in *Much Ado about Nothing* (1598-99). The story of Claudio and Hero had probably for its original a tale of Bandello translated by Belleforest into French. The characters of Beatrice and Benedick, it is supposed, are entirely original creations of the dramatist; there is in them something of his own Rosaline and Berowne, and it was about this time that he re-handled *Love's Labour's Lost*, the play in which we make acquaintance with this earlier pair of lovers. *As You Like It* (1599) and *Twelfth Night* (1600-1) are the last of the wholly joyous comedies of this period. In the former there is indeed a simulacrum of melancholy in Jaques' affectation of that mood as a fashion; but of real gloom, of real sorrow there is not a trace. This charming pastoral comedy is dramatised from a prose tale by Shakespeare's contemporary Lodge, entitled *Rosalynde, Euphues Golden Legacie* (1590), which itself follows the *Tale of Gamelyn*, erroneously introduced as Chaucer's in some editions of the *Canterbury Tales*. In not a few scenes of *Twelfth Night* the mirth is fast and high, but the central comic figure, Malvolio, has something of dignity, almost of majesty, in his extravagant and solemn self-importance. Viola is perhaps the most charming of Shakespeare's maiden masquers in male attire; if she has not the intellectual brilliance of Rosalind, she has even more of maiden sweetness. The plot resembles that of an Italian play *Gl' Ingannati*, and it may also be found in a tale translated into French by Belleforest from Bandello. But the group of jesters and humorists with their victim Malvolio are of Shakespeare's invention.

About the year 1600-1 a change begins to develop itself in the spirit of Shakespeare's writings; his mirth becomes touched with seriousness or infected with bitterness, and soon he ceases to write comedy. Some students have supposed that this transition from a joyous to a sadder temper is connected with events which are shadowed forth in Shakespeare's *Sonnets*. The volume of *Sonnets* was not published until 1609, but Shakespeare's 'sugred sonnets among his private friends' were mentioned by Francis Meres (who gives a very important list of the poet's writings) in his *Palladis Tamia* (1598), and in the following year the *Sonnets* afterwards numbered 138 and 144 were printed in a surreptitious miscellany of verse ascribed to Shakespeare by the bookseller Jaggard, and entitled *The Passionate Pilgrim*. The 1609 edition of Sonnets is dedicated by the publisher T. Thorpe to 'Mr W. H.' as 'the onlie begetter of these insuing Sonnets.' The poems, 154 in number, form two groups—1-126 addressed to a beautiful young man of high station, 127-154 either addressed to or referring to a married woman not beautiful according to the conventional standard, of dark complexion, highly accomplished, fascinating, but of stained character and irregular conduct. The two groups are connected. Shakespeare's young friend and patron, whom he addresses in words of measureless devotion, seems to have fallen into the toils of the woman to whom Shakespeare was himself attached by a passion which he felt to be degrading, yet which he could not overcome. The woman yielded herself to the younger admirer who was socially the superior of Shakespeare. Hence an alienation between the friends, increased by the fact that the youth was now the favourer of a rival poet; but in the close all wrongs were forgotten and the friendship renewed on a firmer basis. Such is the story to be read in the *Sonnets*, if we take them, as they ought to be taken, in their natural sense. But some critics have imagined that they deal with ideal themes or may set forth a spiritual allegory. Many attempts have been made to identify the persons of Mr W. H., the dark woman, and the rival poet. The happiest guess with respect to the last is that he was George Chapman. It has been conjectured that

Mr. W. H. was Henry Wriothesley, Earl of Southampton (the initials reversed), and again that he was William Herbert, the young Earl of Pembroke, who was certainly a patron of Shakespeare. An ingenious argument has been set forth by Mr T. Tyler to prove that the woman of the *Sonnets* was Mary Fitton, a mistress of William Herbert. But it is questionable whether the portraits of Mary Fitton and of Pembroke agree with the indications afforded in the *Sonnets*. In truth the persons have not yet been identified; no conjecture has any but the most insecure support; and it is not likely that the facts so long hidden will ever be revealed.

In his earliest plays Shakespeare tried his hand, as an apprentice in the craft, in many and various directions. In the English historical plays and the joyous comedy he exhibits his mastery of the broad field of human life. But as yet he had not searched the profounder mysteries of our being, nor handled the deeper and darker passions of humanity. About the opening of the 17th century, as we have noticed, a change takes place in the spirit of his creations. He still writes comedy, but the gaiety of the earlier comedies is gone. *All's Well that Ends Well* (c. 1601-2) is least happy in its mirthful scenes; it is at its best where the strong-willed heroine Helena appears, whose task is to seek after and save the unworthy youth to whom she has given her heart. Some critics have supposed that the play as we have it is Shakespeare's rehandling of an earlier version from his own pen originally entitled *Love's Labour's Won*—a play of that name being included in Meres's list of the year 1598. But this theory is incapable of verification. The story came to Shakespeare from Boccaccio through Paynter's *Palace of Pleasure*. *Measure for Measure* (c. 1603) hardly deserves the name of comedy; it is a searching of the mystery of self-deceit in the heart of a man, and the exhibition of an ideal of virginal chastity and strength in the person of the heroine, Isabella. The city life represented in the play is base and foul; the prison-scenes are ennobled by profound imaginative speculations upon life and death. It is the darkest of the comedies of Shakespeare. The subject had previously been handled dramatically in Whetstone's *Promos and Cassandra* (1578), and the same author had told the tale in prose in his *Heptameron of Civil Discourses* (1582). Perhaps it is to this date (1603) that *Troilus and Cressida* belongs, but the chronology as well as the purport of the play is perplexing. It has been suggested that different portions of the comedy were written at different dates; but here again we are in the region of conjecture. Certain passages, as, for example, Hector's last battle, are probably by another hand than Shakespeare's. The sources of the play are Chaucer's poem on the same subject, Caxton's translation from the French *Recuyles, or Destruction of Troy*, and Chapman's *Homer*. Some have even fancied that Shakespeare's design was to turn into ridicule the classical heroes of Chapman, the supposed rival poet of the *Sonnets*. But there is nowhere a nobler representative of worldly wisdom, in a high sense of the word, than Shakespeare's Ulysses. It may be called the comedy of disillusion—a kind of foil to *Romeo and Juliet*. The callow passion of the youthful hero is basely deceived by Cressida, a born light-o'-love; but in the end Troilus masters his boyish despair, and grows firm-set in his vigorous manhood. The contrast between worldly wisdom and adolescent enthusiasm is perhaps the most striking thing in the play.

Before he ceased for a time to write comedy Shakespeare had probably begun that great series of tragedies which occupied him during the opening years of the 17th century. *Julius Cæsar* (1601) and *Hamlet* (1602) are tragedies in which reflection, as a motive-power, holds its own with emotion; in the later tragedies the chief characters are whirled away by passion; here they are misled by thought. In North's translation of *Plutarch's Lives* Shakespeare found admirable material for his Roman plays, and he used it as a true creative poet, and not as a mere antiquary. The Brutus of *Julius Cæsar* is an idealist dealing with practical affairs, constantly in error, yet honoured by us because his errors are those which only a man of noble nature could commit. Cæsar is represented in his decline, with many infirmities, but his presence and power are predominant through the tragedy in the impersonal form of Cæsarism, which sways the spirits of men and compels the catastrophe. *Hamlet* is perhaps founded on an older play, which certainly existed, and produced a great impression on the stage about 1588-89. Shakespeare doubtless read the story, originally derived from Saxo Grammaticus, in the English prose of the *Hystorie of Hamlet* translated from the French of Belleforest. He represents, as Goethe has put it, 'the effects of a great action laid upon a soul unfit for the performance of it.' Hamlet is summoned to avenge his father's murder, but habits of speculation, an excitable emotional temperament, and an untrained will disqualify him for acting the part of a justiciary. He accomplishes his purpose at last, but as it were by chance-medley.

And now tragedy succeeded tragedy, each of surpassing greatness, and all the depths were sounded. *Othello* (c. 1604), founded on a tale given in Cinthio's *Hecatommithi*, exhibits a free and noble nature taken in the toils of jealousy, and perishing in the struggle for deliverance. The betrayer, Iago, is the nearest approach to an incarnation of absolute evil to be found in Shakespeare's plays. *King Lear* (1605) derived some of its substance from an old play on the same subject as well as from Holinshed's Chronicle; the episode of Gloucester and his sons is adapted from Sidney's *Arcadia*. The tragedy is the most stupendous in our literature; the bonds of natural affection, of loyalty, of the amity of nations, almost of the laws of nature, are broken or convulsed; but justice asserts itself in the close, and if Cordelia dies, she dies a martyr of redeeming love. *Macbeth* (c. 1606) is the tragedy of criminal ambition. The source is once again Holinshed. A theory of Messrs Clark and Wright that the play, as we have it, is disfigured by the interpolations of another dramatist—perhaps Middleton—must be regarded as of doubtful worth. The tragedy is distinguished by the unpausing rapidity of its action. In *Antony and Cleopatra* (1607) Shakespeare returns to Roman history, but here Roman manhood is sapped by the sensual witchery of the East. The most marvellous of Shakespeare's creations of female character is surely Cleopatra—Antony's 'serpent of old Nilus.' Such materials for the play as were not supplied by the poet's creative imagination he obtained from Plutarch's life of Antony in North's translation. From Plutarch also came the material for *Coriolanus* (c. 1608). The poet passes from Rome of the empire to the earlier Rome of the consuls, and from the history of a great nature ruined by voluptuous relaxation of its powers to that of a great nature ruined by self-centred pride. As the Roman wife was shown in the Portia of *Julius Cæsar*, so here is presented the Roman mother in the majestic figure of Volumnia. The series of great tragedies closes perhaps with *Timon of Athens* (c. 1607-8), but the play is only in part by Shakespeare. It describes the total eclipse of faith, hope, charity in the undisciplined spirit of Timon, who passes from an easy, indulgent optimism to a wild misanthropy.

Nowhere is Shakespeare a greater dramatic rhetorician than in some of the misanthropist's declamatory speeches. The story was taken from Paynter's *Palace of Pleasure*, and certain gleanings were added from Plutarch and from Lucian.

At this point once again a change shows itself in the spirit of Shakespeare. After passion comes peace; after the poetry of revolt comes the poetry of reconciliation; after the breaking of bonds—the bonds of the family, of the state, and even of humanity itself—come the knitting of human bonds, the meeting of parted kinsfolk, the reconciliation of alienated friends. The last plays of Shakespeare are comedies, but they might be aptly named romances, for romantic beauty presides over them rather than mirth, they have in them elements of wonder and delight, their gladness is purified and rarefied, as the happiness might be of one who has had a great experience of sorrow; the characters move amid lovely, natural surroundings; mountain and sea, the inland meadows, the island shores lend their glory or their grace to these exquisite plays. *Pericles* (1608), or rather Shakespeare's part of that play (Acts III. IV. V., omitting perhaps III. sc. ii. v. vi.), might better be named the romance of Marina, the lost daughter of Pericles. The description of the sea-storm could have come from no other hand than Shakespeare's; the scenes which tell of the recovery by Pericles of wife and child anticipate like scenes in *The Tempest*, *The Winter's Tale*, and *Cymbeline*. The story of Pericles had been told by Gower, who is introduced as 'presenter' of the play, and by Lawrence Twine in his *Patterne of Painfull Adventures* (1607); and there is a novel by George Wilkins (1608) founded upon the play. *Cymbeline* (1609) is also a tale of lost children at length recovered, and of a wife separated from her husband, but finally reunited to him. Something is derived from Holinshed, but with the historical matter is connected a story which in a different form may be found in Boccaccio's *Decameron*. *The Tempest* may have been written late in the year 1610; but it has been ingeniously argued by Dr Garnett that Shakespeare produced it as a court-play on the occasion of the marriage of the Princess Elizabeth to the Elector Palatine, 1613, and that the enchanter Prospero is an idealised and complimentary representation of the 'wisest fool in Christendom,' King James I. No source of the play has been ascertained, but some of the characters and incidents resemble those of Jacob Ayrer's *Die Schone Sidea*, and it is believed that this German play and *The Tempest* must have had some common original. *The Winter's Tale* (1610–11) dramatises a novel by Robert Greene named *Pandosto* (1588); that most delightful of roving rogues, Autolycus, is however a creation of Shakespeare. In Hermione and Perdita we have examples of two contrasted groups of characters represented in Shakespeare's last plays—the aged and experienced sufferers, who have been ennobled by sorrow, and the young who are ennobled by their innocence and pure joy of life.

Apart from the other historical English plays both in subject and in date stands *King Henry VIII.* (1612–13). The play is certainly in part by Fletcher, and an attempt has been made to prove that the remainder is from the hand of Massinger. But we may perhaps accept it as most likely that Shakespeare wrote the following portions: Acts I. i. ii.; II. iii. iv.; III. ii. (to exit king); V. i. The play lacks unity; it has not altogether unaptly been described by Hertzberg as 'a chronicle-history with three and a half catastrophes, varied by a marriage and a coronation pageant, ending abruptly with a child's baptism.' But there is no lack of unity in the conception of those *dramatis personæ* who interested Shakespeare—the king, Wolsey, and above all Queen Katharine, a noble and patient sufferer. Whether we have work by Shakespeare in another play partly written by Fletcher—*The Two Noble Kinsmen*—is more doubtful. Fletcher's collaborator may here have been Massinger, but there are passages which seem beyond Massinger's reach. The play is founded on Chaucer's *Knightes Tale*. If Shakespeare had a hand in *The Two Noble Kinsmen* it was during the last period of his dramatic career. Not so with *Edward III.*, in parts of which some critics believe that they can trace the handiwork of Shakespeare (from king's entrance, I. ii., to end of Act II.); if he was at all concerned with that play it must have been before 1595.

At what date Shakespeare ceased to appear on the stage as an actor we cannot certainly say. He took a part in the representation of Jonson's *Sejanus* at the Globe in 1603 or 1604. In 1610 the Burbages speak of placing him with others as an actor at Blackfriars Theatre; but there are grounds for supposing that he had withdrawn from the stage at that date. In 1607 his elder daughter, Susanna, married a prosperous physician of Stratford, Mr John Hall, M.A., and early next year Shakespeare's grandchild Elizabeth Hall was born. He sold his shares in the Globe probably between 1611 and 1613; but while residing chiefly at Stratford it seems likely that he desired to possess a town residence, for in March 1613 he bought for £140 a house near the Blackfriars Theatre. In the same year the Globe Theatre was burned down while the play of *Henry VIII.* was being enacted, and it may be that stage copies of Shakespeare's plays were destroyed on this occasion. 'The latter part of his life,' says his first biographer Rowe, speaking of his Stratford days, 'was spent, as all men of sense may wish theirs may be, in ease, retirement, and the conversation of his friends. . . . His pleasurable wit and good-nature engaged him in the acquaintance and entitled him to the friendship of the gentlemen of the neighbourhood.' In February 1616 his younger daughter, Judith, was married to Thomas Quiney, a vintner of Stratford. She bore three children, two of whom lived to manhood, but both died childless. Their mother lived on to the days of the Restoration of Charles II. Elizabeth Hall, Shakespeare's first-born grandchild, married Thomas Nash (1626), and secondly, Sir John Barnard (1649). She died without issue in 1670, the last descendant of the poet.

In March 1616 Shakespeare became seriously ill. A draft of his will had recently been made, and now he attached his signature to the several pages of the draft. The bulk of his worldly goods he left to his elder daughter, but Judith was given a considerable sum of money. His sister, Joan Hart, received a legacy of £50 and a life-interest in her house in Stratford. His friends in the country, certain fellow-actors, his nephews, his godson, and the Stratford poor were all remembered. To his wife he left, by an interlineation in the will, and perhaps to indulge some fancy of hers, his second-best bed; she was sufficiently provided for, without special mention, by free bench and dower. On April 23, 1616, which is supposed to be the anniversary of his birthday, Shakespeare died. According to a tradition handed down by Ward, the vicar of Stratford, his last illness was a fever contracted after a merry meeting with Drayton and Ben Jonson. Halliwell-Phillipps supposes that it is as likely to have been caused by the poison of filth and ill-drainage which hung about New Place.

On April 25 the body was laid at rest in the chancel of the parish church, near the northern wall. On a slab which marks the spot are inscribed lines traditionally attributed to Shakespeare.

> Good Friend for Iesus sake forbeare
> To digg the dust encloased heare;
> Bleste be the man that spares thes stones,
> And curst be he that moves my bones

The removal of bones to the charnel-house was then a common practice. During the life of Shakespeare's widow—who died August 6, 1623—a monument was erected in the church, on the chancel wall hard by the grave. It was sculptured by Gerard Johnson or one of his sons. A bust of blue limestone was placed between Corinthian columns of black marble. The head is massive, the forehead lofty and domed, the face that of a cheerful, prosperous man. The poet is represented as composing his works, pen in hand. 'The effigy was originally painted in colours to resemble life. The face and hands were of a flesh colour; the eyes of a light hazel; the hair and beard were auburn. The doublet was scarlet, and the loose gown without sleeves worn over it was black.' Besides this somewhat rude portrait, we possess a portrait-print by Droeshout prefixed to the first folio edition of Shakespeare's works (1623). It is an ill-executed engraving, but is of value as confirming the features of the bust in their general characteristics. These are the only certain portraits. A death-mask, known as the Kesselstadt death-mask, presenting a remarkable and noble face, may possibly be genuine; but the evidence leaves much room for doubt. Of many alleged painted portraits that known as the Chandos portrait has found, perhaps, the widest acceptance.

The central impression which his writings and the story of his life leave upon us with respect to the man Shakespeare is that of the completeness of his humanity, and the sanity which results from such completeness. His life in the world of imagination is the widest and deepest on record; but he was not, like so many of the race of poets, indifferent to the practical, material life. He was certainly a man of strong passions; he was profoundly speculative—in the way of an imaginative thinker—with reference to the problems of the soul; but he learned to control his passions, and to master his excessive tendency to speculation; in the close, he looked down on all of human life with sympathy as from the heights; and yet he did not desert the duties of the common road on which men travel side by side.

The name of the poet may be spelt 'Shakspere,' for we have his autograph signature in that form; but 'Shakespeare,' which appears on the title-page of books which he superintended, is also correct. There is less evidence in favour of the form 'Shakspeare.'

During his life from 1597 onwards several of his plays were printed in quarto (see Halliwell-Phillipps' *Outlines of the Life of Shakespeare*, vol. i., 'Lifetime editions'). After his death the first collected edition of the plays appeared in 1623, in folio, under the superintendence of his fellow-actors Heminge and Condell. It is dedicated to the brothers, the Earls of Pembroke and of Montgomery. Seventeen of the plays contained in the volume had not been published in quarto. The arrangement of the contents is under the three divisions of comedy, history, and tragedy. In 1632 this volume was reprinted (second folio), and again in 1663-64 (third folio) and 1685 (fourth folio). The 1664 issue of the third folio gives seven additional plays—*Pericles; The London Prodigal; Thomas Lord Cromwell; Sir John Oldcastle, the good Lord Cobham; The Puritan Widow; A Yorkshire Tragedy; Locrine.* Some critics have supposed *A Yorkshire Tragedy* may possibly be by Shakespeare, or at least contain touches from his hand.

The first critical edition of the plays is that by Nicholas Rowe (1709). He made some judicious corrections of the text, and gathered a few biographical materials, which he embodied in a brief sketch of Shakespeare's life. In 1725 appeared Pope's edition; some of his critical emendations are happy, and his preface contains admirable remarks on the Shakespearian drama. Theobald, whose edition appeared in 1733, though the object of Pope's ridicule in the *Dunciad*, was a better scholar than Pope; he collated early editions, proposed ingenious emendations, and very materially improved the text of his author. Hanmer in the 'Oxford Edition' (1744), and Warburton in his edition (1747), based on Pope's, made small advance on their predecessors. Warburton's text was severely criticised by Upton, Grey, Heath, and Edwards. The edition of Johnson (1765) is chiefly remarkable for its masterly preface; he rightly came to distrust his own skill as a conjectural emender of the text, and he was not qualified by any profound knowledge of Elizabethan literature for the task of an editor. In 1766 Steevens reprinted twenty of the early quartos, and from 1773 onwards Johnson's editorial work was ably supplemented by that of Steevens. In dealing with the text Steevens was learned and ingenious, but somewhat rash and lacking in reverence. Capell's edition (1768) is the work of a true and laborious scholar. His learned Notes, Various Readings, and the School of Shakespeare were published posthumously in 1783. Much was done by Malone to ascertain the chronological order of the plays and to illustrate the history of the English theatre. In 1780 he edited the poems of Shakespeare and the doubtful plays of the 1664 folio. His edition of Shakespeare's works followed in 1790. He was modest, faithful, learned, judicious, but unhappily was not endowed with a feeling for the beauty of verse. Variorum editions, embodying the work of Johnson, Steevens, and Malone, appeared under the editorship of Reed in 1803 and 1813, and under the editorship of James Boswell (the younger) in 1821. Towards the close of the 18th century Shakespearian critics were much occupied with the forgeries of S. W. H. Ireland. In 1796 the forger made his public confession. The criticism of Coleridge, and in a less degree that of Lamb and of Hazlitt, opened up new and better ways for Shakespearian criticism in the early part of the 19th century. Many valuable editions have been issued since the Variorum of 1821, among which may be mentioned those of Singer, Knight, Collier, Dyce, Staunton, Halliwell, the Cambridge Shakespeare, the Henry Irving Shakespeare. Germany has given us the excellent edition of Delius, and America those of Grant White, Hudson, Rolfe, and the magnificent Variorum edition of certain plays by Furness. The *Sonnets* have appeared in two annotated editions—that of the present writer and that of Tyler. The Shakespeare Society (1841-53) did much to illustrate Shakespeare's writings by reprints from Elizabethan literature; the Collier (*q.v.*) controversy helped to bring the society to an untimely breakdown. The New Shakspere Society (1874 onwards) has carried on the work, and devoted itself in particular to the study of 'verse-tests' as giving indications of the chronology of the plays. A German Shakespeare Society has published annual volumes since 1865. In the bibliography which follows some of the most important of the recent additions to the study of Shakespeare are named.

Concordances: Mrs Cowden Clarke's *Concordance* (to Plays), Mrs Furness' *Concordance to Poems*, Schmidt's *Lexicon.* Grammar: Abbott's *Shakespearian Grammar.* Verse: W. Sidney Walker's *Shakespeare's Versification* and his *Criticisms on Shakespeare* (textual notes), Bathurst's *Changes in Shakespeare's Versification.* Chronology: Stokes's *Chronological Order of Shakespeare's Plays.* Sources: Hazlitt's *Shakspere's Library*, Courtenay's *Commentaries on the Historical Plays*, Skeat's *Shakespeare's Plutarch.* Life: Halliwell-Phillipps' *Outlines of the Life of Shakespeare*, Fleay's *Life and Work of Shakespeare.* Portraits: J. Parker Norris' *Portraits of Shakespeare.* Criticism: Coleridge's *Shakespeare Notes;* Dowden's *Shakespeare, his Mind and Art*, and *Shakespeare Primer;* Hudson, *Shakespeare, his Life, Art, and Characters;* Gervinus, *Commentaries;* Lloyd's *Critical Essays on Shakespeare's Plays;* Mrs Jameson, *Characteristics of Women;* Kreyssig's *Vorlesungen über Shakespeare;* Ulrici's *Shakespeare's Dramatische Kunst.* Dramatic History: Collier's *English Dramatic Poetry and History of the Stage;* Fleay's *Chronicle of the English Drama, 1559-1642;* Ward's *English Dramatic Literature.* Bibliography: Bohn's Bibliography, 'Shakespeare' in Lowndes's Bibliography and Allibone's *Dictionary of Authors*, Thimm's *Shakespeariana*, Mullen's Catalogue of the Shakespeare Memorial Library, Birmingham. The literature in all languages is vast and includes thousands of titles.

See also in this work the articles on Alleyn, Delia Bacon, Bowdler, Boydell, Burbage, Collier, Cowden-Clarke, Delius, Drama, Dyce, Elze, Furnivall, Ulrici, S. W. H. Ireland, Johnson, Knight, Halliwell-Phillipps, Staunton, Steevens, Stratford-on-Avon, Theobald, Tieck, Grant White, &c. Of the French translations the best known are those of Victor Hugo fils (1859-62) and Montégut (1868-73); of the German, those associated with the names of Wieland (in prose, 1762-66), Schlegel (1801-10) and Tieck, Dingelstedt (1865-70) and Bodenstedt (1867-71; 3d ed. 1878).

Shale (another form of the word *scale*—A.S. *sceale*—and akin to *shell*—A.S. *scel*, *scyl*) is the name given by petrologists to any argillaceous rocks which split into thin laminæ—the planes of which are planes of sedimentation. This fissile, laminated structure is not to be confounded with the fissile structure seen in clay-slate (see SLATE). Shale is composed mainly of alumina and silica in variable proportions, but many other ingredients may be present. Some shales, for example, are rich in carbonate of lime (calcareous shale), others contain much ferric oxide (ferruginous shale). Those shales which contain much quartz pass into shaly sandstone. When carbonaceous matter is abundantly present shale often passes into gas-coal, or, it may be, bituminous shale. When it is remembered that shale is of sedimentary origin, and was washed down in the form of fine silt from the land to be accumulated in lakes and quiet areas of the sea-bottom, as in estuaries, protected bays, &c., its variable composition will be readily understood. Shales are frequently highly fossiliferous—the fossils, owing to the impermeable character of such argillaceous rocks, being generally well preserved.

The importance of certain decomposing shales, through which sulphuret of iron is disseminated, for the manufacture of alum has been long known, and the quantity raised for that purpose from the Carboniferous beds of Lancashire and Lanarkshire and the Lias beds of Yorkshire is very considerable, yielding about 16,000 tons of manufactured alum annually. Shales of a similar kind are worked in France, Germany, and North America.

Bituminous shales—i.e. shales more or less rich in carbon and hydrogen—have in recent years attracted much notice as sources of oil for illuminating purposes. Two manufacturing chemists, Butler in 1833 and Du Buisson in 1845, worked patents for the extraction of paraffin from coal-tar. The process introduced by the latter in France of distilling certain bituminous shales at a comparatively low temperature was afterwards tried in England, being used for a time in distilling a Dorsetshire bituminous shale, sometimes called 'Kimmeridge coal.' From this mineral a burning oil, a lubricating oil, and a naphtha for dissolving caoutchouc were obtained. But neither in France nor in England did the attempt to make a profitable manufacture succeed: in the former country the poverty of the shales was the chief drawback; in the latter the disagreeable smell of the oil, which could not be effectually removed, prevented it from obtaining favour in the market.

On account of these failures the process fell into abeyance, until it was revived again by the success of the well-known patent of Mr James Young (see PARAFFIN), secured in 1850 for the production of paraffin and paraffin-oil from coal. With the exception of the solid paraffin, which Mr Young was the first to obtain on the large scale, and the employment of cannel coal instead of shale, the processes of Du Buisson and Young are essentially the same. This process has created a new and rapidly-increasing branch of industry, paraffin-oil and paraffin being economically obtained by it from either cannel coal or shale of certain kinds. Some of these shales yield as much as 30 to 50 gallons of crude oil per ton. Their exploitation has called into existence many large works in the Carboniferous tracts of Scotland, as well as at various localities in England and Wales.

Owing partly to the comparative cheapness of shale, and partly also to the fact that these products are obtained from it in a state more easily purified than when they are got from coal, the use of the latter as a source of them is now almost entirely given up. In Scotland, where the manufacture of paraffin-oil is chiefly carried on, the shales used are called 'oil shales,' and there are now between 1,000,000 and 2,000,000 tons of this material annually distilled. The yield of crude oil, paraffin or burning oils, lubricating oil, paraffin scale or wax, and sulphate of ammonia in various periods of years will be found at the article PARAFFIN. In the refining process the crude oil is reduced to about one-half of its bulk before it is fit for burning. Besides the above, there is also a considerable quantity of 'coal gas' unavoidably produced, and partly wasted. But for the distance of the oil-works, this would be consumed in some of the larger Scottish towns. Shales found in the Lias and some other formations likewise yield mineral oil. See also CLAY, ARGILLACEOUS ROCKS.

Shalloon, a light worsted cloth, believed to have been first made at Châlons-sur-Marne.

Shallot, also ESCHALOT (*Allium ascalonicum*), a species of Allium—Onion—(q.v.), a native of the East, introduced into Europe by the Crusaders—from Ascalon, it is said—and much cultivated for its bulbs, which are used like those of the onion, and sometimes for its leaves, which are used like those of the chive. The leaves grow in tufts like those of the chive, but are larger. The shallot is generally propagated by the cloves, which are planted just beneath the surface of the ground, or only partially beneath it, in spring, and the crop is ready for gathering in July or August. The flavour resembles that of garlic, but is much milder. In the vineyards of Italy the shallot is naturalised.

Shaloo. See DURRA.

Shama. See CAGE-BIRDS.

Shamanism, a name applied loosely to the religion of the Turanian races of Siberia and north-eastern Asia, based essentially on magic and sorcery. Their Heaven-God Ukko is but the chief among a host of nature-spirits capable of being influenced and even forced into obedience by the spells of *shamans* or sorcerers. 'The only trace of the influence of Buddhism,' says Max-Müller, 'among the Kudic races, the Finns, Lapps, &c., is found in the name of their priests, *Shaman* being supposed to be a corruption of *Sramana*, a name applied to Buddha and to Buddhist priests in general.' The Siberian Shaman works his cures by magic, and averts sickness and death by incantations. He works himself up into a frenzy of nervous excitement, beating loudly upon his magic drum, and doubtless is usually the dupe of his own powers. Nor is his superstition any less reasonable than that of the devout Protestant who opens his Bible expecting a divine answer in the first verse on which his eye shall fall; for the latter makes the same assumption that he can compel God to give him an answer, his own faith being the condition. See DIVINATION, MAGIC, and WITCHCRAFT.

Shammai, an eminent doctor of the Jewish law at the time of Herod, head of a most important school, and supreme judge of the Sanhedrim during the presidency of Hillel (q.v.), along with whom he is, indeed, generally mentioned, and of whom he was, as it were, the complement. Very little is known of the history of his life; but he was probably born in Palestine, and he energetically participated in all the political and religious complications of the country. There was a harshness and rigidity in his character, which contrasts most strikingly with Hillel's proverbial patience. His religious views were painfully strict, and he even tried to extend the rigour which he imposed upon himself to the youngest children; but the zealotism with which later times have charged him is not so much to be ascribed to him as to his school—'the House of Shammai.' This seems, under the adverse circumstances of the commonwealth—sedition within, and the approaching enemy without—to have developed a fanatical zeal that at times surpassed all bounds, and strongly fostered that exceptional exclusiveness which proved both the bane and the saving of Judaism. The discussions of the two rival schools, of which that of Shammai preponderated long after the master's death, turned all upon points of positive law.

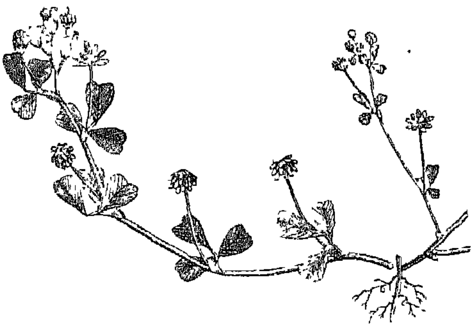
Shammy, Shamoy. See Chamois, Leather.

Shamo, or Gobi. See Asia, Vol. I. p. 486.

Shamo'kin, a borough of Pennsylvania, 188 miles by rail W. of New York, with rich mines of anthracite coal, and (1890) 14,339 inhabitants.

Shampooing. See Bath, Massage.

Shamrock (Irish, *seamrog*), the national emblem of Ireland, a leaf with three leaflets, or plant having such leaves, sometimes supposed to be the Wood-sorrel (see Oxalideæ), which unlike some of the rival claimants for the honour is certainly indigenous to Ireland. But the name is more frequently given to some species of Clover, or to some common plant of some of the nearly allied genera, as the Bird's-foot Trefoil (see Bird's-foot), or the Black Medick. It is not improbable that the name has a sort of general reference to plants with trifoliate leaves indigenous to Ireland; a perfectly satisfactory determination of the species is apparently as impossible as the attainment of botanical accuracy in regard to the emblematic thistle of Scotland. Lesser Yellow Trefoil (*Trifolium minus*) is the plant usually sold in Dublin on St Patrick's Day. The Common White Clover (q.v., *Trifolium repens*) has had a superstitious respect attached to it from early times, and is frequently treated as the Irish shamrock; though it is believed to have been but recently introduced into Ireland, where it is not so common as in England. According to the elder Pliny, no serpent will touch it; and the luck attached to the finding 'four-leaved clover'—a leaf with four leaflets instead of three (a not very uncommon monstrosity in clover, though very rare in wood-sorrel)—still causes many a futile search. The shamrock is said to have been first assumed as the badge of Ireland from the circumstance that St Patrick made use of it to illustrate the doctrine of the Trinity. But the story is a late one, and is not found in any of the earlier lives of St Patrick; and so far as the theological argument is concerned, any plant with trifoliate leaves would answer the saint's purpose equally well.



Lesser Yellow Trefoil (*Trifolium minus*).

Shamyl (i.e. Samuel), chief of the Lesghians and leader of the independent tribes in the Caucasus in their thirty years' struggle against all the might of Russia, was born at Aul-Himry in northern Daghestan, became a priest or mollah, and laboured with zeal and religious fervour to compose the numerous feuds of the Caucasian tribes and unite them in antagonism to their common enemy, the infidel Russians. He was one of the foremost in the defence of Himry against the Russians in 1831. In the end of 1834 he was elected 'imam,' or head of the Lesghians, and soon made himself absolute temporal and spiritual chief of the tribes of Daghestan. He at the same time introduced a change of military tactics, abandoning open warfare for surprises, ambuscades, &c., which brought numerous, and sometimes great, successes to the arms of the mountaineers. In 1839 the Russians succeeded in hemming Shamyl into Achulgo in Daghestan, took the fortress by storm, and put every one of the defenders to the sword in order to be quite certain that Shamyl should not escape. But by some mysterious means he did escape, and suddenly appeared preaching with more vigour than ever the 'holy war against the infidels.' Ten years later he again escaped from the same stronghold after the Russians had made themselves masters of it. The Russians were completely baffled, their armies sometimes disastrously beaten by their unconquerable foe, though he began to lose ground through the long continuance of the struggle and the exhaustion it naturally brought with it. During the Crimean war he was helped by the allies, who supplied him with money and arms; but after peace was signed the Russians resumed their attacks upon the Caucasian tribes with more energy, opened a road over the mountains, thus cutting off one portion of the patriots, and so compelled their submission. On April 12, 1859, Shamyl's chief stronghold, Weden, was taken after a seven weeks' siege, and his authority, except over a small band of personal followers, was wholly destroyed. For several months he was hunted from fastness to fastness, till at last (September 6, 1859) he was surprised on the plateau of Gounib, and after a desperate resistance, in which his 400 followers were reduced to 47, he was captured. He was assigned a residence at Kaluga in the middle of Russia, with a pension of £1000, and he died at Medina in Arabia in March 1871, having taken up his residence in Mecca the year previously. In faith he was a Sufi.

Shanghai, the most important seaport for central China, stands on an affluent of the Yang-tsze-kiang, about 12 miles from its mouth and 160 miles SE. of Nanking. The Chinese city, with narrow, filthy streets, is surrounded by a wall, and between it and the river lie densely-crowded suburbs. On the north of the Chinese city the French and English settlements, with broad streets, well lighted, well paved, and handsome houses and public buildings, stretch northwards parallel to the river. The English cathedral was designed by Sir G. Scott. Powerful batteries guard the river-approach. The city lies low, and suffers greatly from dysentery, cholera, and fevers during the very hot summers. Here is the court of appeal for all the foreign consular courts of China and Japan. Shanghai has an enormous trade in tea and silks, and in cottons, woollens, opium, and metals, besides innumerable other commodities. It taps the provinces of middle China by a vast and complicated system of interlacing canals, and so gets the lion's share of the tea and silk to export. The total trade of the port, excluding the junk trade (of which no customs returns are made), has grown enormously since Shanghai was thrown open to foreign commerce in 1842; in 1890 and the years immediately preceding it the gross trade of the port was valued at an average of £37,853,000 annually, or a little more than the trade of Hull, the third port of England. Hong-kong with a trade worth £41,000,000 annually is the only port in China that surpasses Shanghai. A large proportion (£22,715,000) of the grand total of the trade of Shanghai is for goods (foreign and native) that are re-exported abroad and to other Chinese ports—i.e. for goods in transit. Native produce from the immediate neighbourhood of Shanghai is exported to the annual value of £8,746,000; this is of course in addition to the foreign and native re-exports. The actual imports reach a total of £16,814,000 for purely foreign goods (including goods from Hong-kong), and £12,293,000 for native Chinese produce. The share of Great Britain in the total trade (nearly two-thirds for imports) amounts to £8,180,000 a year; next comes the trade with Hong-kong (four-fifths for exports), with India (nearly all for exports), with Japan (two-thirds exports), and with the United States (£2,393,600, five-eighths imports). Silk and silk goods are exported to the value of £7,690,000, and tea to £2,686,000; next come raw cotton (£1,523,000), rice, sugar, paper, straw-braid, medicines, tobacco, skins and hides, native cloth, hemp, wool, wheat, oils, flower and fruit seeds, fans, and a host of minor articles. Indian tea is gradually supplanting China tea in the markets of the world, and the Chinese planters are beginning to grow cotton instead of tea. The imports of greatest value from foreign countries (including Hong-kong) are cotton goods of all kinds (£9,948,000), opium (£3,249,000; this item is steadily declining), metals, woollens, coal, kerosene oil, bêche de mer, edible birds'-nests, dyes, ginseng, matches, pepper, sandalwood, seaweed, timber, shark's fins, &c. The port is entered annually by some 2900 vessels of 2,700,000 tons burden; of these nearly one-half with more than half the tonnage are British, and only 900 of 710,000 tons are Chinese. Pop. 380,000 (about 3000 foreigners).

Shanklin, a watering-place on the south-east coast of the Isle of Wight, 8 miles by rail S. of Ryde. Pop. (1881) 2740; (1891) 3277.

Shannon, the largest river of Ireland, rises in the Cuilcagh Mountains, County Cavan, and falls after a course of 254 miles into the Atlantic Ocean between Loop Head and Kerry Head. Flowing south-westwards, it soon reaches Lough Allen in Leitrim; thence it proceeds through a succession of expansions—Loughs Boderg, Bofin, Forbes, Ree, and Derg—past the towns of Carrick, Athlone, and Killaloe, to Limerick. There it departs from the southerly direction it has hitherto pursued and turns westwards, forming a wide estuary some 70 miles long and 10 miles across at its seaward extremity. About 10 miles from the entrance the river narrows to about 1½ mile in width. Outward navigation commences at Foynes, which is connected by railway with Limerick, and from which steamboats ply daily to Kilrush, Tarbert, and the intermediate stations. Vessels of 1000 tons can, however, get up to Limerick, and small steamers to Athlone; boats ascend the river to beyond Lough Allen. Several tributaries fall into the Shannon, as the Suck and Fergus from the right, and the Inny, Brosna, Mulkear, Maigue, and Deel from the left. The main river is canalised for some distance below Athlone, and again between Killaloe and Limerick. This important system of navigation, which occupies a position almost midway between the east and west coasts of Ireland, is connected with Dublin by means of the Grand and Royal Canals.

Shanny. See BLENNY.

Shans, a number of tribes of common origin, who live on the borders of Burma, Siam, and China, to which three states they are in great part subject, though some are independent (see map at Vol. II. p. 562). They are the descendants of an aboriginal race of China; their home generations ago was in the mountainous region on the borders of the Chinese provinces of Sze-chuen and Shensi. In the course of time they have been pushed southwards. They seem to have entered the valley of the Irawadi in the 6th century B.C. The Shans and the Laos are one and the same people, and both are closely akin to the Siamese. The country the Shans inhabit may be broadly described as a succession of wide river-valleys (of the Menam, Meping, Mekok, Mekhong, &c.) separated by high ridges; on the north it climbs up to the Yunnan plateau of southern China. There are extensive and valuable forests of teak; iron, rubies, and silver are extracted, and gold, copper, coal, and petroleum are known to exist. Rice, cotton, and tobacco are the crops most extensively grown. The people are noted for chased work in gold and silver. The tribes that acknowledge the supremacy of Siam are estimated to number 2,000,000 people; at the census of 1891 it was computed that there were about the same number under British rule in Burma. The number of Shans subject to China, and the numbers of the independent tribes, are alike unknown. But equally whether tributary or independent, they are distributed amongst several states, of which the most important are Zimmé (Chieng-Mai), Kiang Hsen, Luang-Prabang, Lapon, Nan, Lakhon, and Peh, all tributary to Siam; and Kiang Hung, Kiang Tung, Mone, Katchin, and others now incorporated in Burma. The Shans are an indolent, laughter-loving people, fond of gambling and cock-fighting, not unwarlike, though orderly and fairly trustworthy; the women have great influence, and enjoy equal freedom with the men. Slavery, however, exists, but in a mild form; and serfdom is general. The rule of the native chiefs is generally just and mild, and taxation is light. Buddhism is the dominant religion, though it is mingled with many superstitious practices. Zimmé and others of the principal towns are the seats of a very extensive transit trade between Yunnan, Tali, and the marts of southern China, on the one side, and Bangkok and the ports of Burma on the other; the traders, mostly Chinamen, bring down from Yunnan silks, iron and copper utensils, opium, straw-hats, beeswax, figured cloth, tea, and walnuts, and take back cotton, raw and woven, and European manufactured goods. There is also a large trade in the native commodities—horns and hides, ivory, cutch, gold-leaf, saltpetre, sapan wood, salt, lead, steel, betel-nuts, stick-lac, &c. Since 1881 Messrs Hallett and Colquhoun have been advocating the construction of a railway from Bangkok to Kiang Hsen, on the northern frontier of Siam, and thence to Ssumao on the Chinese border, with a branch-line of 100 miles from Maulmain in Burma. Other alternative routes are proposed to the commercially very important provinces of southern China; the one which apparently the government of India favours is an extension of the Burman system northwards from Bhamo.

The first Shan state to rise to the level of historical importance was the Mau kingdom, the ruler of which in the 13th century conquered all Burma, the upper parts of Siam and the Malay Peninsula, and made his influence felt from Tali in China as far as Java and Cambodia. All the northern portions of this extensive empire, including Burma, were ruled by Mau princes down to 1554. Shortly after that date the tables were turned, and most of the Shan states became tributary to the emperor of Pegu. Other powerful states about the same period were Zimmé and Vien-chang. The former still exists, but subject to Siam; the latter, a Laos state, was destroyed in the 18th century. About 1774–77 Siam drove out the Burmese and Peguans, and made herself mistress of the southern Shan states, Zimmé and Vien-chang. Ruins of large cities exist in great numbers throughout the middle portions of the Shan country; they are the relics of the ephemeral capitals of different Shan states.

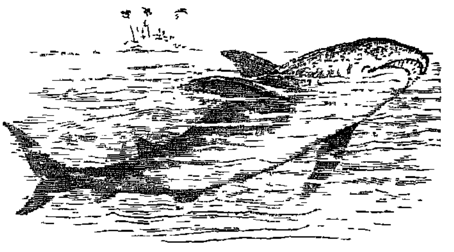
Shari (i.e. *river*), the principal feeder of Lake Tsad (q.v.) or Tchad.

Shark, a common name for most of the Elasmobranch fishes included in the sub-order Selachoidei. They are voracious fishes, with two or three exceptions carnivorous, the smaller forms often eating crustaceans and molluscs, as well as fishes, to which the larger forms almost exclusively restrict themselves. They sometimes devour men who swim incautiously in warm seas. Unlike the flattened rays, the sharks usually preserve the typical fish-like form, and the gill-slits are lateral, not ventral. In most the skin is covered with minute thickly-set skin-teeth, really like those of thornbacks, but much smaller and more numerous. The teeth on the jaws are very sharp, generally triangular, and are disposed in rows. In most cases only the row on the ridge of the jaw is in use, but as this is worn away it is replaced by the next row, which is gradually moved forward. Some of the sharks are viviparous, others are oviparous. In the latter each egg is enclosed in a horny 'mermaid's purse.'

As to their distribution, sharks, though most numerous in the tropics, are represented in almost all seas, and many venture up estuaries and rivers. One species occurs in Lake Nicaragua. Many live in the open sea, and voyagers know how they follow the ships, hungrily swallowing—with little discrimination—what refuse is thrown overboard. Though few are like the Portuguese Shark (*Centroscymnus cœlolepis*) in living in deep water, not a few live a sluggish existence at the bottom of relatively shallow water near the shore. Many of the smaller forms are gregarious, and prey upon the shoals of herring and mackerel.

The classification of sharks has not yet been placed on a thoroughly firm basis. Günther recognises the following families. Carchariidæ include the genus Carcharias, of which the Blue Shark (*Carcharias glaucus*), 12–15 feet in length, and the larger White Shark (*C. vulgaris*) are representative; the genus Galeocerdo, with several formidable species; the genus Galeus, of which the Tope (*Galeus canis*) occurs on British coasts; the genus Zygæna, notable for the large transverse eye-bearing lobes of the snout to which these voracious fishes owe their name Hammer-heads (q.v.); the genus Mustelus, with small species known as 'Hounds.' In *Mustelus lævis* and *Carcharias glaucus* there is a peculiar placenta-like connection between the mother-fish and the yolk-sac of the unborn young.



White Shark (*Carcharias vulgaris*).

Lamnidæ include numerous large pelagic sharks, such as the Porbeagle (*Oxyrhina cornubica*), which frequents the North Atlantic, attains a length of 10 feet, and is said to swallow its prey whole; the Man-eater Shark (*Carcharodon rondeletii*), in all tropical and temperate seas, attaining a length of 36 feet; the Fox-shark or Thresher (*Alopecias vulpes*), not uncommon around British coasts, attaining a length of 13 feet, notable for the enormously elongated upper lobe of its tail, and for its voracious attacks on herring and mackerel; the Basking-shark (*Selache maxima*), attaining a length of 30 feet, living on small fishes, often in the habit of lying passive, and like the thresher harmless to man unless attacked. The *Challenger* explorers dredged numerous large teeth belonging to some shark of the genus Carcharodon; as these measured 5 inches along the side and 4 across the base, there must be some larger species than *Carcharodon rondeletii* either still alive or not long since extinct.

Notidanidæ are a small family including a few tropical or subtropical sharks, sometimes called cow-sharks, and referable to the genus Notidanus, from which, however, some distinguish two other genera, Hexanchus with six gill-slits, and Heptanchus with seven.

Scylliidæ are a family of small sharks, usually called dog-fishes, including *Scyllium canicula* and *S. catulus*, the common dog-fishes of British shores; *Stegostoma tigrinum*, a beautiful striped shark frequenting the Indian Ocean; and the Indo-Pacific ground-shark (Crossorhinus), which lurks on the bottom, and is protectively coloured.

Cestraciontidæ, a family now somewhat decadent, twenty-two of the twenty-five genera being extinct. The living forms—e.g. *Cestracion* or *Heterodontus galeatus*—are called Port Jackson sharks. The front teeth are small and sharp, those behind are flat and arranged in pavement-like rows.

Spinacidæ are a family including the small spiny dog-fishes—e.g. *Acanthias vulgaris* and *A. blainvillii* on British coasts; the voracious Greenland Shark (*Læmargus borealis*), which attains a length of about 15 feet; the Black Dog-fish (*Centroscyllium fabricii*) of Arctic seas; *Centroscymnus cœlolepis*, which is caught off the coasts of Portugal from a depth of 400–500 fathoms; the Spinous Shark (*Echinorhinus spinosus*), a Mediterranean form, which seems also to live in deep water.

Rhinidæ are a family represented solely by the almost cosmopolitan, somewhat ray-like, Angel-fish or Monk-fish (*Rhina squatina*).

Pristiophoridæ are a family parallel to the Pristiuridæ among the rays, for the genus Pristiophorus has its snout prolonged into a saw as in the much larger genus Pristis.

It seems necessary furthermore to establish a family for a remarkable Japanese shark, *Chlamydoselachus anguineus*, a somewhat eel-like animal, 6 feet long, less than 4 inches in diameter, suggestive of a sea-serpent, but more important since it seems as if it were a direct descendant of forms which flourished in Devonian times (see FISHES).

Sharks are destructive to food-fishes and to fishermen's nets, and sometimes attack man himself. On the other hand, many of the smaller forms are eaten by man; the gristly fin-rays are used in China in the making of gelatine; the livers are sometimes utilised as sources of oil; the skin of those which are thickly beset with skin-teeth was formerly much used by cabinet-makers for polishing purposes, serving, under the name of shagreen, instead of sandpaper.

Sharon, the name of an extensive tract of plain and corn-land (partly under cultivation) in Palestine, lying between the sand-dunes of the coast and the foot-hills of the interior, and extending from the neighbourhood of Carmel on the north to near Joppa. The so-called Rose of Sharon is the subject of an article.

Sharon, a borough of Pennsylvania, on the Shenango River, 71 miles by rail NNW. of Pittsburgh. Its manufactories include rolling-mills and foundries, steel and boiler works, a chain-factory, planing and flour mills, a soap-factory, and machine-shops; and coal is largely mined near by. Pop. (1890) 7447.

Sharp, a sign ♯ in Music, which, when prefixed to a note, elevates it by a semitone in the scale. See MUSIC, Vol. VII. p. 357. A double sharp × raises a note two semitones.

Sharp, ABRAHAM, a meritorious mechanist and astronomer, who, born at Little Horton near Bradford in 1651, and apprenticed to a tradesman, became a schoolmaster, and acquired a thorough knowledge of mathematics and the cognate sciences. Having also acted as exciseman and bookkeeper in a London office, he was in 1688 asked by Flamsteed to assist in mounting instruments at Greenwich Royal Observatory. There for some years he did admirable work on the instruments, perfecting hand-graduation and other processes, and making many very valuable observations; and after retiring to Horton, he continued to assist Flamsteed by his extraordinary powers as a calculator. He published tables of logarithms and a treatise, *Geometry Improved* (1717), and made observations in a small observatory fitted up by himself. He died 18th July 1742. See his *Life and Correspondence*, edited by Cudworth (1889).

Sharp, GRANVILLE, abolitionist, was the son of the archdeacon of Northumberland, and was born at Durham in 1734. He came to London, and, after studying law, obtained a post in the Ordnance Office; but this he resigned in 1777 on the outbreak of the war with America, of which he disapproved. He was the author of upwards of sixty-one publications—mainly pamphlets—on philological, legal, political, and theological subjects (the English tongue, hundreds and tithings, the definite article in the Greek Testament, Hebrew syntax and pronunciation, Melchisedek, Armageddon); but his principal writings and the main labours of his life were in defence of the negro, and for the abolition of the slave-trade and slavery. He defended the cause of the negro Somerset, securing the decision of the twelve judges (1772) that whenever a slave touches English soil he becomes free. He was with Clarkson one of the founders of the Association for the Abolition of Negro Slavery, and assisted in the establishment of the colony of Sierra Leone for freedmen. He died in London, 6th July 1813. There is a Life by Hoare (1820), and a smaller one by Stuart (New York, 1836). See also SLAVERY.

Sharp, JAMES, Archbishop of St Andrews, was born at the castle of Banff on 4th May 1618, the son of the sheriff-clerk of Banffshire. Educated for the church at King's College, Aberdeen (1633–37), he afterwards visited England, and became acquainted with several eminent English divines, as Hammond, Sanderson, and Taylor. In 1643 he was appointed a 'regent' of philosophy at St Andrews, and in 1648 minister of Crail, an office which he held throughout Cromwell's ascendency. In 1651, however, when Monk was reducing Scotland to obedience, Sharp was carried off to England with several other ministers; but he quickly regained his liberty, and for some years enjoyed the confidence of the 'Resolutioners,' or more moderate party in the church. In 1656 he was chosen by them to plead their cause in London before the Protector against the 'Protesters;' and Baillie speaks of him on this occasion as 'that very worthy, pious, wise, and diligent young man.' On the eve of the Restoration he was sent up again to London to use his utmost endeavours with Monk in favour of the Kirk of Scotland, and at Monk's suggestion he crossed over to Breda, and had several interviews with Charles II. His correspondence for some months after his return from Holland is full of apprehensions of Prelacy, 'cassock-men,' and the Service-book; but its perfidy stands revealed in his letter of 21st May 1661 to Middleton, which proves that he was then (as probably before) in confidential communication and hearty co-operation with Clarendon and the English bishops for the immediate re-establishment of Episcopacy in Scotland. The bribe was a great one, for on 16th December he was consecrated Archbishop of St Andrews, having first received Episcopal re-ordination. The supple and dexterous tool of Middleton or Lauderdale, as either gained the ascendency, a liar and coward, and a vindictive oppressor of those he had betrayed, he soon became an object of detestation to the populace and of contempt to his employers. When in 1668 Robert Mitchell, a conventicle preacher, fired a pistol at him in the streets of Edinburgh, the bystanders suffered the fanatic to escape—only, however, to be executed ten years later on his own confession, enticed from him by an assurance of his life. At last, on 3d May 1679, on Magus Muir, twelve Fife Covenanters—Hackston of Rathillet, John Balfour of Kinloch, the rest peasants or artisans—fell in with him as he was driving with his daughter to St Andrews, and, dragging him from his coach, hacked him clumsily to death in spite of his frantic prayers. In his epitaph at St Andrews Sharp is described as 'a most pious prelate, a most prudent senator, and a most holy martyr;' but to-day even his apologists can plead little for him but that he was not licentious, that his portrait is not that of a monster of cruelty, and that he was simply an ambitious ecclesiastic of plausible and courtly manners, who may have thought that, if there must be an archbishop of St Andrews, there was no great reason why he should not be the man

See vol. vii. of Hill Burton's *History of Scotland* (ed. 1874); O. Airy's *Lauderdale Papers* (Camden Soc. 1884); an article in the *North British Review* (1848); and two in the *Scottish Review* (1884–85).

Sharp, William (1749–1824), an engraver, republican, and enthusiast, who was born in London, and died at Chiswick. See his Life by W. S. Baker (Phila. 1875).

Sharpe, Charles Kirkpatrick, virtuoso, was born at Hoddam Castle, Dumfriesshire, 15th May 1781, and in 1798 entered Christ Church College, Oxford, where he graduated B.A. in 1802. In 1813 he fixed his bachelor home in Edinburgh (No. 93 Princes Street), and here he died in March 1851. A Scottish Horace Walpole (with a difference), he was a great collector of pictures and curios, was a clever versifier and a cleverer draughtsman, wrote for the *Anti-Jacobin*, contributed two original ballads to the third volume of Scott's *Minstrelsy*, and edited several club-books, but is chiefly remembered nowadays by his immense correspondence, two big volumes of which have been edited by Alexander Allardyce (Edin. 1888).

See the Memoirs prefixed thereto and to his *Etchings and Prose Fragments* (Edin. 1869), and a third in Mark Napier's *Memoirs of Montrose* (4th ed. 1856).

Sharpe, Samuel, biblical scholar, was born in London, March 8, 1799, a descendant of Philip Henry and nephew of Rogers the poet, in whose bank he worked till sixty. From an early age he took to the study of Egyptology, and his *Egyptian Inscriptions* (1836–41–56) showed creditable learning and more than creditable industry. Later books were a *History of Egypt* (1846) and a *History of the Hebrew Nation and Literature* (1869); a translation of Griesbach's text of the New Testament (1840), a revision of the Authorised Version of the Old Testament (1865), besides works on Hebrew grammar, on the chronology of St Paul's epistles, &c. Sharpe was a man of singular amiability, a Unitarian in religion, honest and painful beyond most; but his work suffered from the deficiencies in his training, the over-ingenuity natural to a self-educated man, and the lack of knowledge of the work of contemporary German scholars. He died in Highbury, July 28, 1881. See the Life by P. W. Clayden (1883).

Sharpshooters, an old term applied in the army to riflemen when skirmishing or specially employed as marksmen. Any soldier or sailor might now be called a sharpshooter under certain circumstances.

Shâstra, or Shâster (Sansk. *S'âstra*, from *s'âs*, 'to teach'), means literally a book; but the term is especially applied to the authoritative, religious and legal, books of the Hindus.

Shat-el-Arab. See Euphrates.

Shaving. See Beard.

Shaw, Jack, life-guardsman. See Pugilism.

Shawl (Persian *shâl*). As may almost be inferred from the simplicity of its form, this garment is of high antiquity. Even the elaborately-wrought and beautiful shawls of India and Persia have been continuously made from an early time. Sir George Birdwood (*Industrial Arts of India*) suggests that the description of rich apparel in Ezek. xxvii. 23, 24, may refer to Cashmere shawls imported into Tyre through Aden. The patterns of these shawls, but little changed in the course of centuries, are sometimes produced by weaving and sometimes by a kind of embroidery, but in either case the work is slow and tedious. Cashmere shawls are made of a very fine material called *pashm* or *pashmina*, consisting of the inner or under-wool of the shawl-goat of Tibet (see Cashmere Goat). This wool is separated with much care from the longer hair of the animal, and is then cleaned and spun with great delicacy into a fine thread, the best quality of which sells as high as from £2 to £2, 10s. per lb. The dyeing of the yarn is a very important and difficult operation, almost all the colours from native dyes being permanent. Unfortunately aniline dyes were and may still to some extent be used, but they are now practically prohibited.

In the case of those shawls which have their patterns produced by needlework or embroidery the ground consists of a plain pashmina fabric, and the thread used for the pattern is of the same material. The shawls with loom-woven patterns, notwithstanding their intricate nature, are made on very rude and primitive looms. Three or sometimes four weavers are engaged at one of these looms, and instead of using shuttles they work with numerous wooden needles (each being supplied with coloured yarn), which have slightly charred ends but no eyes. The shawls are woven face downwards, and the work is carried on at the back or reverse side, on which the needles hang in rows. After the threads are worked in to suit the pattern across one line of weft, they are knotted to the warp and driven firmly into their place by the reed or comb. On an average five shawls are produced on one loom in a year, but a loom may be occupied during this period with only one shawl if it is of very fine quality and of an elaborate pattern. These shawls are, however, often woven in separate pieces and so neatly joined together that a shawl so made looks as if it had been woven in one piece.

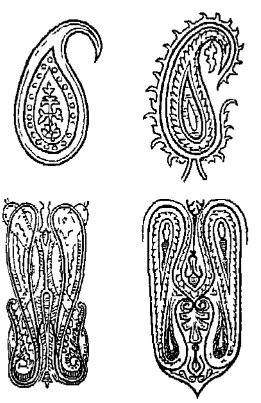
Exceptionally fine Cashmere shawls are high in price. Mr Baden Powell (*Manufactures of the Punjab*) states that one of first-rate quality, weighing 7 lb., will cost in that country as much as £300. This price is made up of the following items: Material, £30; wages of artisans, £150; duty, £70; miscellaneous expenses, £50. But in the case of an exported shawl we must add customs duty, cost of carriage, commission to broker who manages the sale and export, something for the risk of robbery, which by some routes is great, and other incidental expenses. These shawls are, however, made as low in price as £15 for one in eight colours and of comparatively simple design.

Inferior shawls are manufactured in the Punjab by artisans who at various times have emigrated from Cashmere. They are woven at Amritsar, Ludhiana, Jalalpur, Nurpur, and a few other places. For these the fine pashm is mixed with another kind of goat's wool called *koork* from Kerman in Persia. Shawls somewhat resembling those of Cashmere, though much less costly, are largely manufactured at Kerman itself, the koork of which they are made being, like the pashm from the Tibetan goat, the under-wool of the animal. But the most beautiful shawls woven in Persia are made of silk, and these too are like fine Cashmere shawls in general appearance. Both in India and Persia shawl-cloth is made into tunics and other shaped articles of dress for both men and women.

The production of shawls was until recent years a very important manufacture in France, and gave occupation to a large number of designers in Paris, who not only furnished designs for those woven in their own country—chiefly at Paris, Lyons, and Nîmes—but also for shawl-manufacturers in England and Austria, and even for some woven in Cashmere. In 1867 it was estimated that the annual value of the French shawl trade amounted to nearly a million pounds sterling. Shawls of various kinds are made at different places in England, and in past years many of these were designed in the Indian style. At Paisley in Scotland, where for many years previous to 1860 the manufacture of shawls was of great importance, the trade originated in the beginning of the 19th century. They were made of silk, wool, or cotton, either separately or in combination; but the best-known class of Paisley shawls was manufactured of fine wool and with patterns in the style of those woven in Cashmere. As many as 8000 looms were at one time occupied in the weaving of these. Soon after the middle of the century, however, the manufacture began to decline, and for some years past no shawls of this character have been woven. Tartan shawls, but chiefly of small size, for indoor or occasional wear, are still made at several places in Scotland.

The change which has taken place during the last quarter of a century in the nature of female costume is remarkable. Tweed fabrics and other soft woollen cloths of a plain character, similar to those worn by men, have completely taken the place of the richly-patterned shawls and plaids of former days. Even in a country like Persia, where, as has been stated, shawl-stuff formed part of the attire of both sexes, the characteristic native dress, so long tenaciously adhered to, is gradually being abandoned for coats and other garments of European broadcloth. The time has at last come when the shawl-fabrics of Cashmere, which for many centuries have never ceased to charm the female world, are no longer in demand, and the art of manufacturing them is in danger of becoming lost.

A few words may be said about the patterns of Cashmere shawls, which have been placed by the most distinguished decorative artists of modern times in the highest order of art manufacture. The most characteristic feature in a typical design is what has been usually called the 'cone' or 'pine cone,' of which a few varieties are shown in the annexed figures. It appears, however, to be really a conventional representation of a wind-bent cypress-tree, as the term *sarv*, the native name of that tree, is also applied to this pattern or part of a pattern. The form has many modifications, one or more of which often make up the groundwork of the designs of other textile fabrics both in India and Persia, and it even appears on metal-work and papier-maché made in Cashmere. Sometimes it is simply called the shawl pattern. It is, however, not merely the graceful outline of their ornamental devices, but also the harmonious blending of their deep toned colours, which gives a singular charm to these exquisite productions of eastern looms.



Shawnees, a tribe of American Indians of the Algonquin family, formerly settled mainly in New York, Pennsylvania, and Ohio, but driven westward by the Iroquois. They helped the French against the English, gave trouble to the newly-founded United States, and in 1812 some bands joined the English. They afterwards removed to Missouri, Kansas, and Indian Territory.

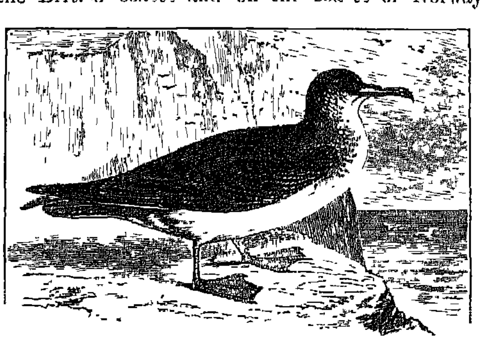
Shea Oak, or SHE OAK. See CASUARINA. For Shea Butter, see BUTTER-TREE.

Shear-steel. See STEEL.

Shearwater, a genus of birds belonging to the petrel family, Procellariidæ, included by Linnæus in the genus Procellaria, but separated by Brisson in 1760 as the genus Puffinus. These birds vary from 8½ to 14 inches in length. The bill is rather longer than the head; the mandibles are compressed and decurved; the nostrils open separately, not by a common tube; the wings are long and pointed; the legs are of moderate length; the tarsi are compressed laterally; the three toes in front are webbed, and the hind-toe is very small. The genus includes twenty or more species, and is cosmopolitan in its distribution. The shearwaters, however, are exclusively oceanic species. They spend most of their time on the wing, and can swim with great ease, but rarely if ever dive. They are usually silent, but at their breeding-grounds they utter soft agreeable notes. Their principal food is fish. A single white egg is laid in a hole in the ground. The species found in the British Isles are classified by Seebohm thus:

Lores and upper ear-coverts same colour as the crown.	Sooty Shearwater (under parts uniform brown).	
	Great Shearwater	
	Manx Shearwater	wing 9½ inches or under.
	Dusky Shearwater	

The Sooty Shearwater (*Puffinus griseus*) has been found on the east and south coasts of England and Ireland, and is generally distributed over the North Atlantic, but has its breeding-grounds in the southern hemisphere. The Great Shearwater (*P. major*) is common on the south coast of England, but comparatively rare on the east coast. It occurs rarely in Scotland and Ireland, and it visits the south of Greenland. Southwards it extends to Tierra del Fuego and to near the Cape of Good Hope. Nothing is known of its nesting. The Manx Shearwater (*P. anglorum*) is common round the British coasts and on the coasts of Norway and Iceland and even Greenland. Southwards it reaches the Mediterranean and the Black Sea and the Azores, Madeira, and the Canary Islands. This species is nocturnal or crepuscular in habits and dives freely. The Dusky Shearwater (*P. obscurus*) is a rare visitor to the British Isles. It frequents the Canaries, Madeira, Bermudas, Bahamas, and Barbadoes. It is a nocturnal species.



The Manx Shearwater (*Puffinus anglorum*).

Sheathing. See SHIPBUILDING.

Sheave. See PULLEY.

Sheba. See SABÆANS.

Shebeen (Irish), a term in use, especially in Ireland and Scotland, for a house where intoxicating liquors (usually whisky) are sold without a license. See LICENSING LAWS.

Sheboygan, a port, capital of Sheboygan county, Wisconsin, on Lake Michigan, at the mouth of the Sheboygan River, 53 miles by rail N. of Milwaukee. It has a good harbour, and contains foundries, tanneries, breweries, and planing-mills, and manufactures shoes, chairs, toys, &c. Pop. (1880) 7314; (1890) 16,359.

Shechem. See NABLUS.

Shechi'nah. See ARK OF THE COVENANT.

Shee, Sir Martin Archer, portrait-painter, was born at Dublin, 23d December 1770, studied under West, and as a boy of sixteen became famous as a portrait-painter. In 1788 he settled in London, where he became A.R.A. in 1798, R.A. in 1800, and President of the Royal Academy in 1830, when he was knighted. He was regarded as a rival of Lawrence, though his art was but poor and few of his portraits are now thought much of. He wrote several poems, didactic, tragic, and other; a novel; and a *Plan for the Encouragement of Historical Painting.* He died at Brighton, 19th August 1850. See the Life by his son (2 vols. 1860).

Sheeahs. See Shiites.

Sheen. See Richmond.

Sheep (*Ovis*), a genus of ruminant quadrupeds of the family Capridæ, so nearly allied to goats that the propriety of generic distinction is very doubtful. They differ from goats in having the outline of the face more or less arched and convex; the horns spiral, sometimes very large in the males—in domestication, however, wanting in many breeds; the chin destitute of a beard; a sac or pit between the toes of each foot, lined with hair, and secreting a fatty matter. Upper incisors and canine teeth are wholly wanting: see Bovidæ, Capridæ. It is supposed by some that all the wild sheep existing in different parts of the world are mere varieties of one species; and it is impossible to say from which of the wild species the domestic sheep is sprung.

All the wild sheep known are natives either of mountainous regions or of dry and elevated tablelands. They are gregarious, a character which the domesticated sheep fully retains. They are generally seen in small flocks, and are not easily approached, taking refuge in flight, a sharp whistling sound emitted by one of the rams serving as an alarm to the whole flock; although they are very capable of making a vigorous defence when driven to close combat. A ram of the domestic species is indeed able to sustain a conflict with a bull, taking advantage of his far greater agility, and butting against his foe with his strongly armed forehead. A ram has been known to throw a bull on the ground at the first onset, and is always ready to defend himself and his companions against a dog. Many rams exhibit great pugnacity. Sheep differ from goats in their mode of fighting; goats rear themselves on their hind-legs, and throw themselves sideways on their adversary, to bring the points of their horns to bear; whereas sheep rush straight at each other, a mode which better suits the different style of armature of the head. Rams of the black-faced variety are especially powerful with their heads, and often at the rutting season kill each other. Their naturally strong skull is further protected in battle by heavy arched horns. A thorough ram fight is a terrifying sight. The two warriors go backwards each some fifteen or twenty yards, and then meet each other with great violence, their heads cracking loudly, and their beam-ends rising in response to the collision of heads. Ewes of this breed fight also. Sheep without horns are not usually so pugnacious as the mountain breeds.

All the wild sheep have short wool, with an outer clothing of long and nearly straight hair. But even the long hair has usually the peculiar character of wool, in that roughness of surface which gives it the property of *felting* (see Hair, Wool, Felt). One effect of domestication in the common sheep has been to cause the disappearance of the outer long hair, and to produce instead an increase of the length and abundance of the wool, an object of great importance to the sheep-farmer. In neglected breeds of the common sheep the two kinds of hair or wool are very apparent. In some tropical climates the sheep loses its abundant fleece, and is covered with hair little longer than that of the ox.

Although not equal to goats in their adaptation to rocky steeps, and not endowed with such power of leaping from crag to crag, most breeds of sheep exhibit a strong disposition to seek their food in places where no animal not very agile and sure-footed could venture; and those of the domesticated breeds which retain much of their original wildness are thus adapted to situations in which otherwise the pasture would be of little value to man. In fine weather sheep ascend the heights, and in cold and stormy weather they repair to the lower grounds. In modern times it has been customary to remove the large flocks from mountainous regions to lower grounds to pass the winter; and in the fall of the year shepherds have difficulty in preventing the animals from leaving the summer pastures too early if the weather is unfavourable. On the other hand, if fine spring weather sets in before the period of removal from the winter-quarters, the flocks keep pressing towards the summering regions. Mountain sheep have favoured spots whither they go regularly over-night, and the ewes generally have choice localities to which they go to lamb. They get much attached to certain pastures, and many of them have been known to return stealthily, in the course of a few days, to their native or appreciated pastures, though removed many miles.

A very interesting species of the wild sheep is the Great Mountain Sheep (*Ovis poli*) on the Thian Shan and other lofty chains of central Asia: 12½ hands high, the horns (each some 6 feet long) forming a wide open curve. It was met with by Marco Polo (hence the technical name), but has only lately been studied or seen. The Argali (*O. ammon*), found east and north of it, is the subject of a separate article. The Moufflon (*O. musimon*) is the wild sheep of the mountains of Greece, Corsica, and Sardinia. The Rocky Mountain Sheep, or Big-horn (*O. montana*), of North America, is equal in size to the Argali, which it much resembles also in its general appearance. The flesh is of the very finest quality. The wool is very fine, and fully an inch and a half long; it is completely concealed by long hairs. The general colour is brown, paler on the lower parts; the old rams are almost white in spring. The Big-horn is found from Nebraska to the Pacific coast-ranges, and from the Rio Grande northward to 68°, and occurs in herds of from three to twenty or thirty. The Aoudad (*O. tragelaphus*), a native of the north of Africa, inhabiting chiefly the lofty parts of the Atlas Mountains, has the throat, the chest, and front of the forelegs adorned with long shaggy hair.

The Common Sheep (*O. aries*) was probably the first animal domesticated by man; Abel, the 'keeper of sheep,' brought an offering unto the Lord 'of the firstlings of his flock and of the fat thereof;' and lambs were amongst the most frequent sacrificial offerings of the Jews. The felting and weaving of wool were unquestionably among the earliest of the arts. The wool was probably at first pulled from the skin, a cruel practice which long survived in some places. Sheep-shearing is often referred to in Scripture. The leather made of the skin of the sheep is much employed in bookbinding, and for making gloves. In patriarchal times the milk was much used, as it still is in some countries; it is richer than cow's milk, and the cheese made of it has a sharp taste and strong flavour, which, however, are greatly relished by some. In some mountainous parts of India the sheep is even used as a beast of burden, carrying loads of from 35 to 40 lb. up steep crags, where almost no other animal could be employed.

Those who watch sheep carefully, or keep them as pets, find them by no means devoid of intelligence. They have, however, a stupid habit of following, without scruple, the leader of the flock; so that, when sheep are being driven across a narrow bridge, or where a fence separates the road from a precipice, if anything occur to deter them from proceeding in the proper path, and one break over the fence or parapet, more of the flock may be expected to follow, as has sometimes happened, to their utter destruction. Sheep very soon come to know the voice of the shepherd, and also the appearance as well as the bark of the shepherd's dog. Though they stand more in awe of the shepherd's voice or commands than of any other human being's, the dogs that regularly move amongst them fail to keep them in such subjection as strange ones do.

The 'rutting' is from September till the middle of December, according to the variety of sheep and the system of feeding. White-faced modern breeds have the tups early among them, and the hill flocks are later. The period of gestation is from 20 to 21 weeks. Ewes occupying sown or low-ground pastures lamb in January, February, and March, while those not so well provided for—the mountain sheep—do not drop their lambs usually till April. The ancient breeds generally have only one lamb in a season, but modern highly-fed varieties frequently have twins, occasionally triplets, but rarely more. There is at least one variety in England, the Dorset Horn breed, which produces two crops of lambs each year. Lambs intended to come early into the market are as often as possible dropped in January. Generally lambs are weaned in July and August. Weaning of breeding or store lambs, however, is a feature of modern sheep-farming; at one time it was not uncommon to see several generations persistently following the parent stem. The shearing season ranges from the 1st of May till the middle of July, according to the description of sheep, the nature of the feeding, &c. Autumn is the most common time for the 'dipping,' 'juicing,' or 'smearing' of the flocks, to kill vermin, prevent skin disease, and preserve and cultivate the wool crop.

The great object for which the ancient Britons possessed sheep before the Roman invasion was the production of wool. The demand for meat has now raised the value of mutton and lamb so much, that the farmer finds it profitable to devote much of his attention to supplying the market with these articles; and those breeds of sheep are reckoned most valuable which are most suitable for this purpose, even although the crop of the wool is inferior. When there was no food for sheep but the natural pasture, the animals could not be fattened for the market except during summer, and not until they had attained an age of three, four, or five years; whereas much of the mutton now consumed is the flesh of sheep not more than two years old, fattening being aided by turnips, mangold, other green food, oilcake, and grain.

The young branches of heath, and in lower situations the shoots of furze, often serve as food for sheep, when the supply of grass fails. Sheep delight in the short grass and peculiar herbage of hill pastures and bare downs; and the mutton produced in such pastures, and by the breeds most suitable to them, is of superior quality to that of the large fat sheep fed on richer soils. The latter are also more liable to many diseases, particularly where the ground is at all moist. Aromatic and bitter herbs are particularly relished by sheep.

The breeds of sheep are very numerous, and very different.—The Black-faced Sheep of the Highlands of Scotland and of the north of England is perhaps as near the original type as any existing breed. Both male and female have horns; those of the ram large, with two or more spiral twists, those of the ewe much smaller, and little twisted. The face and legs are not always black. Many are speckled, and some principally white. The black-faced sheep is robust, very active, and hardy; enduring the rigours of a severe winter when sheep of most of the breeds common in Britain would perish. It survives on little food, and shifts admirably for itself in a snowstorm. The small quantity and even inferior quality of food with which a black-faced sheep will tide over a snowstorm is most surprising. So great indeed is the tenacity of life in black-faced sheep that they have been known to be buried five weeks under a snow-wreath and come out alive. It has a bright, quick eye, with an expression very different from that softness which is seen in many of the breeds preferred for lower grounds and better pastures. The wool is long and coarse, and the weight of the fleece from 3 lb. to 5 lb.; but the mutton is of the finest quality; and on this account, and its hardiness, this breed is preferred to any other in many mountainous districts and on rough elevated moors.—The Welsh Sheep is much smaller than the black-faced; both sexes horned; the colour various; the mutton highly esteemed; the fleece seldom weighs 2 lb.—A very little larger breed with big bushy tail, hornless, or with short and little twisted horns, has long existed in the Shetland and Orkney Islands, its wool affording the material for the manufacture of Shetland hosiery. The Shetland and Orkney sheep are very hardy, and in winter feed much on seaweed.—Smaller than either of these, and indeed remarkably diminutive, is the hornless Breton Sheep.—The Forest Sheep of England, so called from being pastured in the royal forests, has now been supplanted by other breeds. The original forest sheep was generally small, with face and legs russet brown or gray, wild, restless, and difficult to fatten, but producing wool of fine quality.—The Dorset Sheep is one of the best of the old English upland breeds. Both sexes have small horns. The wool and mutton are of medium quality; but the ewes are remarkable for their fecundity, and the abundance of their milk—two crops of lambs being bred and reared by them each year. This breed is valued as affording a supply of early lamb for the London market.—The Ryeland Sheep has long existed in Herefordshire and some neighbouring counties of England. It is small, short-limbed, white, hornless; produces excellent mutton; and before the introduction of Merino wool its wool was preferred to every other kind for the manufacture of the finest broadcloths.—The Cheviot Sheep has existed from time immemorial on the Cheviot Hills, and is now very widely diffused over a considerable part of England and a large extent of Scotland, being hardy and well adapted for high grounds, although it is inferior in hardiness to the

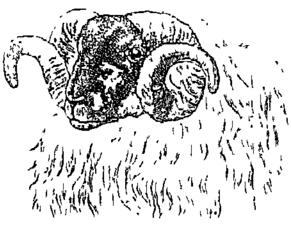


Fig. 1.—Black-faced Ram.

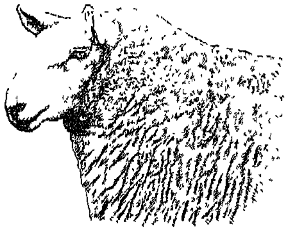

Fig. 2.—Cheviot Ewe.

black-faced. Cheviots, however, rather excel the black-faced both in size and in the value of the fleece, but require a richer pasture. Ewes are hornless, and the rams almost so. The general figure is longer than that of the black-faced sheep. They are narrow in shape, with slender forequarters and long pricked ears. The colour is white, the face and legs occasionally mottled with gray, but generally quite white. The fleece weighs from 3 to 5 or 6 lb. Great attention has for many years been devoted to the improvement of this breed.—The Leicester Sheep is another of the most valuable breeds. This breed, as it now exists, is a result of the skill and care of Mr Bakewell (q.v.), who, soon after the middle of the 18th century, began to make experiments for the improvement of the old Leicester sheep—a large, coarse-boned sheep, not easily fattened, and with coarse long wool, of which, however, the fleece weighed from 8 to 10 lb. The new Leicester sheep has wool moderately long, of better quality, the average weight of the fleece being about 7 or 8 lb., and is easily rendered very fat. It is naturally very broad on the back, with finely-arched ribs. The colour is white. Both sexes are hornless. The Leicester sheep is now common in all but the mountainous parts of Britain; and other breeds have been improved by crossing with it, particularly various breeds of long-woolled sheep, which have long existed in different parts of England, as those of Lincolnshire, Romney Marsh, &c. The Leicester, indeed, was the first to be submitted to improvement by a systematic system of breeding, and in the general improvement of the sheep stock of the British Isles it has played a larger part than any other breed. One of the most valuable crossed breeds is the Border Leicester.—A famous long-woolled breed is that called the Cotswold or Gloucester, the wool of which was in great esteem in the 14th and 15th centuries, bearing a higher price than any other wool. In 1464 Edward IV. sent a present of Cotswold rams to Henry of Castile; and in 1468 a similar present was sent to John of Aragon. The Cotswold breed, however, as it now exists, has been modified by crossing with the Leicester, and produces shorter wool and better mutton than in former times. — The South Down Sheep has recently been improved with the utmost care. The colour is generally white, and the face and legs are generally brown or fawn. Black and spotted faces and legs were once common, but these are discounted now. Both sexes are hornless. The wool is short, very close, and curled. The South Down derives its origin and name from the chalky downs of the south of England, but is now met with throughout England and the south of Scotland.—The Shropshire sheep are large, with thick wool something like the South Down. They are hornless, and black or dun in the face and legs. They come early to maturity, but are suited only for finer climates and good keep.—The Hampshire, also hornless, is a valuable breed of sheep for fattening, matures early, and grows to a large size. It originated in a cross between the Old Wiltshire horned sheep and the Old Berkshire Knot with the South Down.—The Oxford Down, a successful blend of the Hampshire and Cotswold breeds, is a heavy, somewhat soft sheep, without horns, and capable of rapid and great development under good treatment. It is not suited to very cold and exposed situations.—The Lincoln, a cross between the improved Leicester and the native sheep of the county, is one of the best long-woolled varieties in England. The fleece of the Lincoln Sheep is long and lustrous in the staple, and often exceeds 20 lb. in weight. Other English varieties of good standing are the Suffolk Down, Devon Long-wools, Romney Marsh Sheep, the Lark and Wensleydale Sheep. The Roscommon is the principal native breed in Ireland. They are large hornless sheep, improved from the native sheep by a cross of the Leicester.

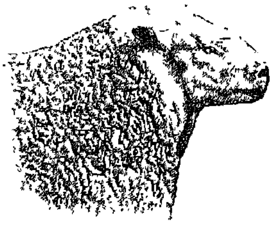

Fig. 7.—Lincoln Ram.

The first sheep were taken to what is now the United States in 1609, merinos not till 1801; but now 95 per cent. of American sheep are mainly of merino origin, though the breeds have not been kept pure. The principal breeds are native, Spanish, and Saxon Merinos; the New Leicesters or Bakewells; Southdowns, Cotswolds, Cheviots, and Lincolns. The Texas sheep are largely crossed with a Mexican breed, originally from the Basque provinces of Spain. Two races, originating in America, have been allowed to die out—the Smith's Island and the Otter breeds—the latter with a long body and short legs.—Sheep-raising is carried on more or less extensively in Texas, New Mexico, in the Rocky Mountain states, in the uplands of the south-west, in Ohio, and in the northern New England states.

The merino is an important breed of sheep, originally Spanish, but now widely diffused throughout Europe and North America, and constituting a great part of the wealth of Australia. The merino has large limbs, and the male has large spiral horns, which do not rise above the head; the skin of the neck is loose and pendulous; the cheeks and forehead bear wool; the fleece, which is very heavy, often in choice animals exceeding 20 lb., sometimes even over 30 lb., is fine, long, soft, and twisted in silky spiral ringlets, abounding in oil, which attracts dust, so that it has generally a dingy appearance. The fleece is sometimes black, and black spots are apt to appear even in the most carefully bred flocks. The merino sheep fattens slowly, and owes its value altogether to the excellence of its wool. It has not been found profitable in Britain, where the production of mutton is a great part of the object of the sheep-farmer. Merinos are the main breed in Australia, sometimes variously modified by crossing with English long-woolled sheep. In New Zealand the Lincoln, Romney, Leicester, and Cotswold breeds are largely represented, as they do not suffer so much from foot-rot as merinos, and their flesh of course tastes more like English mutton.

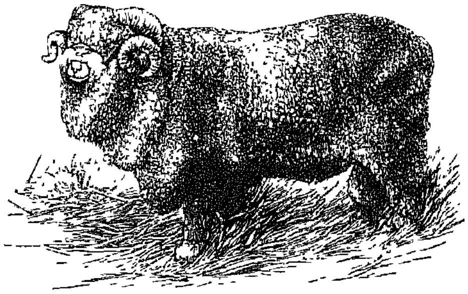

Fig. 8.—Merino Ram.

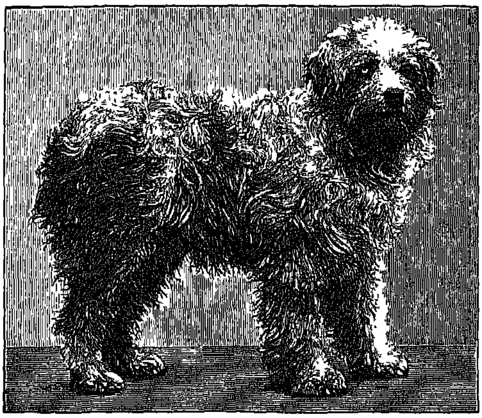
A clever shearer will clip twenty-five to thirty sheep in a day, some even exceeding that number. Sheep-shearing by machinery has at last been successfully introduced. The Wolseley Sheep-shearer, invented and brought into notice in Australia, consists of a cutting wheel geared to the shaft of a small steam-turbine, which is worked by a current of steam conveyed from the boiler in an india-rubber tube. A comb moves in front of the cutter, effectually protecting the animal from injury. The shearing apparatus, made of brass and in shape similar to a small trowel, is held in the hand and guided over the body of the sheep just as is the ordinary wool shears. The shearing-machine works with great expedition and perfect safety to the sheep. It will be of great advantage where flocks are large and labourers few.

The Iceland Sheep is remarkable for very frequently having three, four, or five horns—a monstrosity found also in northern Russia.—The north of Africa possesses a breed of sheep with legs of great length, pendulous ears, and much-arched face; the wool short and curled, except on the neck and shoulders, which have a kind of mane.—India has also a hornless breed, with pendulous ears, short tail, and very fine much-curled wool.—The Broad-tailed or Fat-tailed Sheep is found in many parts of Asia, in Barbary, and is now abundant in Cape Colony. It is rather of small size, with soft and short wool. Its chief characteristic is the enormous development of the tail, by the accumulation of a mass of fat on each side, so great that the tail has been known to weigh 70 or 80 lb. The tail is highly esteemed as a delicacy, and to protect it from being injured by dragging on the ground the shepherd sometimes attaches a board to it, or even a small carriage with wheels.—The Fat-rumped Sheep of southern Tartary has a similar accumulation of fat on the rump.—The Astrakhan or Bucharian Sheep has the wool twisted in spiral curls, and of very fine quality.—The Circassian Sheep has a remarkably long tail, covered with fine long wool, which trails on the ground.—The Wallachian Sheep, common in Hungary, as well as in Roumania, is distinguished by the size and direction of its horns, which after one spiral turn rise up from the head to a great length. The wool is soft, and is concealed by long hair.

In the article AGRICULTURE tables are given on pp. 100–1, showing the number of sheep in the United Kingdom at different dates; and similar statistics are scattered up and down the work in such articles as NEW ZEALAND and UNITED STATES. The importance to Britain of foreign supplies of mutton may be gathered from the articles of FOOD and PRESERVED PROVISIONS. The rapid growth of this trade in recent years may be seen from the single fact that, whereas the trade of exporting mutton from New Zealand was in 1883 only worth £116,000, it had before the end of that decade attained a value of over £700,000. Reference should be made to the article WOOL, and for sheep diseases to the articles on Anthrax, Bot, Braxy, Fluke, Foot-rot, Murrain, Smallpox, Sturdy, &c. See works by G. S. Heatley (1884), C. Scott (1886), J. H. Steel (*Diseases*, 1890); Stephens, *Book of the Farm* (new ed. by Macdonald, 1889); Wallace, *Farm Live-stock of Great Britain* (1885; new ed. 1889), and *Rural Economy and Agriculture of New Zealand and Australia* (1891).

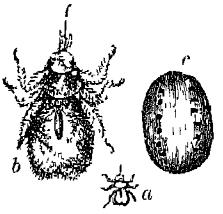
Sheep-dog, a name which often includes the Scottish Collie (q.v.), but which is more properly applied to the English drover's dog. The Sheep-dog or Smooth-coated Collie performs the same work for the south-country shepherd as the rough-coated for the northern one. The sheep-dog is built on more sturdy and powerful lines than the collie, but lacks the speed of the latter. His coat is short, thick, and wiry; and he is not so graceful as the collie, though possibly quite as useful. Another variety of the sheep-dog is the Bob-tailed or Moorland Collie.



Bob-tailed Sheep-dog, 'Wall-eye'd Bob.'
(From a Photograph by Gambier Bolton, F.Z.S.)

When the game-laws were more stringent farmers were only allowed to keep a dog with a docked tail, the current belief being that hares cannot be coursed with success by dogs with docked tails. This treatment long continued is sometimes alleged (though doubtfully) to have made the short tail hereditary. The bob-tailed collie has a long, shaggy, and curly coat over body, legs, and head. The colour is generally a gray or grizzle. As a cattle-dog he surpasses the other varieties, and is also often used for sheep.

Sheep-louse, or SHEEP-TICK, or (in Scotland) KAID (*Melophagus ovinus*), an insect of the family Hippoboscidæ, to which also the Forest Fly belongs, ranked in the order Diptera, although in this genus the wings are completely wanting. It lives among the wool of sheep, particularly of lambs, sucking the blood of the animal, and is most abundant in the early part of summer. Where it fixes its head in the skin a round tumour is formed. The body of the insect is compressed and smooth, of a rusty colour, the head and thorax are small, the abdomen is large. The female does not lay eggs, but, like the other Hippoboscidæ, hatches the egg and nourishes the larva within her own body, till it passes into the pupa state, when it is deposited. oval-shaped and shining, and fastened to the wool of the sheep. Sheep-farmers use various arsenical and carbolic washes or *dips* for the destruction of these parasites. The sheep-tick is not a tick proper, not being one of the Ixodidæ. See TICK.



Sheep-louse (*Melophagus ovinus*):
a, natural size; *b*, magnified; c, the pupa, magnified.

Sheepshanks, JOHN, a munificent art-patron who left his priceless collection of pictures to the nation, was born at Leeds in 1787, and succeeded on his father's death to the management of an extensive and prosperous cloth manufacture. Retiring from business, he devoted himself to collecting the works of modern British artists, especially those of Landseer, Mulready, and Leslie. These in 1856 he presented to the nation; and his collection of over 230 oil-pictures and some 100 drawings and sketches were sufficient to furnish out three rooms at South Kensington. He died at London, 6th October 1863.—His brother, the Rev. Richard Sheepshanks (1794–1855), did valuable work as an astronomer, and in helping to restore the British standards of weights and measures, destroyed in 1834 by the burning of the Houses of Parliament.

Sheepshead (*Diplodus probato cephalus*), an American fish of the family Sparidæ, allied to the perches. It occurs along the east coast from southern Florida to Cape Cod. The name refers to the shape and colour of the head, and to the teeth, which are broad blades in front and grinding molars on the sides of the jaws. The sheepsheads live near the bottom, especially about oyster and mussel beds or about wrecks, feeding on molluscs and barnacles. In the south they often ascend rivers. Except in spring, when they spawn, they live gregariously. In size they vary greatly, from 2 to 12 pounds weight. They afford good sport to anglers. The Scup or Porgie (*Stenotomus chrysops*) is nearly allied, and not very far removed is the fresh-water Drumfish (*Haplodinotus grunniens*), to which the name sheepshead is also applied.

Sheep-stealing, in England, is a felony, and by statute 24 and 28 Vict. chap. 96, sect. 11, is punishable with penal servitude to the extent of fourteen years. In Scotland it is an aggravated species of theft, and under certain old statutes was punishable by death. These statutes have been long ignored, and sheep-stealing, like other thefts, has been punished by imprisonment or penal servitude at the discretion of the judge. And by the Criminal Procedure (Scotland) Act, 1887, a capital sentence is no longer competent in the Scotch courts except on conviction of murder or murderous offences.

Sheerness, a strongly fortified seaport and royal dockyard in Kent, on the north-west extremity of the Isle of Sheppey, at the confluence of the Thames and Medway, 11 miles ENE. of Chatham and 52 E. of London by rail. It consists of four divisions, Blue-town, Mile-town, Banks-town, and Marina-town, and of these the first is within the limits of the garrison. The dockyard, dating from 1814, is one of the finest in Europe, and covers 60 acres, comprising wet and dry docks, immense storehouses, and official residences. The harbour is usually crowded with vessels of all descriptions. At Garrison Point are the residence of the port-admiral, the telegraph, coastguard station, and barracks. The chief trade is in supplying the requirements of the employees in the various government establishments, and in the export of corn seeds and of oysters from the neighbouring oyster-beds. The neighbourhood was once thought to be very unhealthy, but important sanitary works have been carried out, and there are now few towns the population of which enjoy better health. The sea-bathing is excellent. Pop. (1851) 8549; (1881) 14,286; (1891) 13,841. Sheerness was captured by the Dutch under De Ruyter in 1667, and here the mutiny of the Nore (q.v.) broke out in 1798.

Sheers. The elemental form of a pair of sheers consists in two spars fastened together near the top with a pulley at the point of junction, and held by a rope fastened to any convenient object, in such a position that the weight lifted hangs nearly between the spars. This forms an easily improvised crane. An apparatus of this kind of great height and strength is used for masting vessels. In the principal dockyards there are tall permanent sheers, mounted either on the side of a masting-dock or on a floating *sheer-hulk*, often an old dismasted ship devoted to this use.

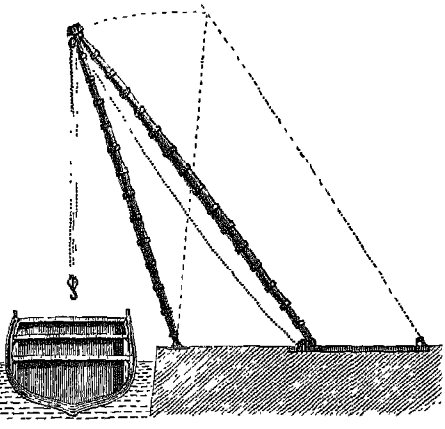


Diagram of Sheers.

Sheffield, a municipal, parliamentary, and county borough in the West Riding of Yorkshire, in a hilly country, at the confluence of the Sheaf with the Don, 46 miles SSW. of York, 18 SW. of Doncaster, 38 S. of Leeds, 41 E. of Manchester, and 165 NNW. of London. In 1875 and the succeeding years a street improvement scheme was carried out at a cost of upwards of half a million; and now the town, generally, is well built. It possesses many fine public buildings, such as the original parish church of St Peter, supposed to have been erected in the reign of Henry I., 240 feet long by 130 feet broad; St Mary's Roman Catholic Church (1850), surmounted by a spire 195 feet high; the Albert Hall (1873), cutlers' hall, corn exchange; the new market-hall, or Norfolk Market, with a roof of glass and iron, erected in 1851 by the Duke of Norfolk at a cost of about £40,000; music-hall, assembly rooms, theatres, &c. The foundation of a new town-hall, to be crowned with a colossal statue of Vulcan, was laid in October 1891. There are extensive botanic gardens, and several fine cemeteries; many churches; numerous educational establishments, such as the Free Grammar-school, the Wesley College (1838), and a Technical School. The Firth College, opened in 1879, has a principal and eleven other professors or lecturers. Board schools provide 34,754 school places, and voluntary schools 29,495. The Mechanics' Institution dates from 1832. There are free and other public libraries, an Athenæum, and a Literary and Philosophical Society. The charitable institutions comprise an infirmary and several hospitals. Sheffield has long been noted for the manufacture of Cutlery (q.v.); and at the present day an endless variety of articles in brass, iron, and steel is produced at the many manufactories with which the town abounds, such as knives of every description, silver and plated articles, Britannia-metal goods, coach-springs, spades, spindles, hammers, files, saws, boilers, stoves, grates, buttons, &c. The introduction of the manufacture of armour-plates, railway-springs, tires, and rails, since 1871, has given a remarkable impetus to the growth of the town. Sheffield has several public parks (one presented in 1878), and two sets of public baths. Mr Ruskin founded the St George's Museum here (formerly at Walkley, but since 1890 in the town itself), in which he deposited an important collection of minerals, illuminated manuscripts, engravings, and drawings. Mr J. Newton Mappin bequeathed to the town a collection of pictures, and Sir F. T. Mappin, Bart., M.P., his nephew, has since added largely to the collection. The Mappin Art Gallery was erected by the executors of Mr J. N. Mappin at a cost of £15,000. Pop. (1821) 69,479; (1841) 111,091; (1861) 154,093; (1881) 284,508; (1891) 324,243.

Situated on the extreme southern border of Yorkshire, Sheffield has from Saxon times been the capital of a district known as 'Hallamshire,' which is composed of five contiguous parishes, and formed the manor of Earl Waltheof, who married the Countess Judith, the Conqueror's niece. A Norman family, who seem to have sprung from Lovetot, a small hamlet in Normandy near Fontenelle, became the resident proprietors of Sheffield and the adjacent parishes; and William de Lovetot founded a monastery at Worksop in 1103, and built a church at Sheffield. This family established a market, a hospital for the sick, a mill for grinding corn, and a bridge over the Don during their brief reign in Sheffield. The property descended to a female heir, whose hand was given in marriage by King Richard I. to Gerald Furnival, who had fought with his king at Acre. The Furnivals took the side of Henry III. in his contests with the insurgent barons, during which an expedition was formed against the town and castle of Sheffield, when many of the inhabitants were slaughtered, and the castle was burned in 1266. Four years after this disaster Thomas de Furnival rebuilt the castle. His son, of the same name, was the great benefactor to this town. Though much employed as a soldier against the Scots, he enfranchised his vassals, and gave them a court of justice and trial by jury. His grandson took part in the battle of Crécy; and his brother, who succeeded him, left an only daughter, who married Sir Thomas Nevil. This pair again left an only daughter, who married the great hero, John Talbot, first Earl of Shrewsbury, familiar from Shakespeare's *Henry VI.*

During the wars betwixt the rival Houses of York and Lancaster the Shrewsbury family sided with the latter, and the second earl fell in the battle of Northampton fighting for the king. His son and successor was again in arms in the same cause, but died young, and left a son, who was only five years old when he succeeded to the title and property, which he held for seventy years. This earl made Sheffield Castle a more permanent place of residence than his predecessor had done. It was a spacious fortified building which covered four acres of ground, and fourteen acres of pleasure grounds were attached, and stood at the northern entrance to the town betwixt the rivers Sheaf and Don. In the early part of the reign of Henry VIII. the earl built a more homelike residence about two miles from the town, in which Wolsey rested for eighteen days on his last journey (1530), and the utter ruins of which still bear the name of 'Sheffield Manour.'

The earls of Shrewsbury were amongst the very chief of the nobility of England, and the sumptuousness of living which they maintained, both at the castle and manour, was second only to that of royalty itself. Queen Elizabeth imposed on George Talbot, sixth Earl of Shrewsbury, the odious responsibility of holding Queen Mary of Scotland a prisoner in his castle at Sheffield; and this lasted, with only few and short changes of abode, during the long period of fourteen years (1572–86).

The seventh Earl of Shrewsbury left three daughters, of whom only the youngest, whose husband was Thomas, Earl of Arundel, had a child. Through this son the vast estates connected with the Sheffield property became henceforth vested in a line of descendants which has made the Dukes of Norfolk owners and lords of Hallamshire. Lord Arundel was non-resident, living much abroad, and the prosperity of Sheffield deteriorated greatly owing to the withdrawal from the local markets of all such custom as two grand mansions had hitherto afforded. Whilst the noble family maintained their loyal sentiments towards the king in the national contest, the townspeople took the popular side. In August 1644 the castle was besieged and taken by the parliamentary army, and soon afterwards a resolution was passed by the government that it should be 'sleighted and demolished.'

Sheffield henceforth became dependent upon its cutlery trade. This, as the special business of the town, had existed from the earliest times. The 'Sheffield whittle' spoken of by Chaucer in the 14th century was the common knife used for all purposes by those whose social rank did not entitle them to carry a sword. It was only the commonest cutlery that was manufactured in the town, and neither swords nor daggers nor the more modern bayonet were ever made here. The Cutlers' Company, which has now a national reputation, was founded in 1624, and the cutlers' annual feast may date from about that time, having originated in the permission granted by Earl Gilbert to the 'apron men,' or working smiths, to pull down as many deer as they could kill in the park and carry away with their hands. Up to the middle of the 18th century Sheffield was a mean place, and the cutler was a poor man; the income of £100 a year was accounted as riches. But in a century from that time, with railway approaches, the use of the steam-engine, machinery of every sort, and a variety of processes for the manufacture of steel, Sheffield had risen into the position of being the 'capital of steel' in Britain, and perhaps in the world; it was the first place at which the armour-plates to protect British war-ships were rolled, and here too are cast the steel blocks which are subsequently bored and rifled for the artillery of both services.

Till 1845 the whole town was included in one parish, having a single ancient church, with five modern churches that were merely chapels of ease. There are now thirty-seven ecclesiastical parishes, with their churches and clergy. The various Nonconformist bodies, too, have rapidly increased with the growth of population. The old dissent commenced with the ejection of the Presbyterian clergy in 1662, of whose churches the Upper Chapel in Norfolk Street is now the lineal representative. Sheffield was first enfranchised by the Reform Bill of 1832; and by the bill of 1885 the borough was divided into five parliamentary districts, each being represented by one member. In March 1864 a new embankment, constructed for the Sheffield Water Company, at Bradfield, gave way, and let out a body of water 95 feet high from a reservoir 78 acres in extent. The destruction of life and property by this flood was unprecedented in England: 250 persons perished; mills, houses, and hamlets were swept away from their foundations, and, apart from the ruin of the Bradfield Dam, damage was done to private property to the extent of close upon £300,000. In 1866 trade outrages, in the form of 'rattening,' long a discredit to Sheffield, were put an end to.

See Joseph Hunter's *Hallamshire* (1819; new ed. by the present writer, 1869); the latter's *Sheffield, Past and Present* (1873); R. E. Leader's *Reminiscences of Old Sheffield* (1875); and *Harper's Magazine* (June 1884).

Sheffield, JOHN, DUKE OF BUCKINGHAMSHIRE, was born in 1649, and succeeded to the title of his father, the second Earl of Mulgrave, in 1658. He served in the navy against the Dutch in 1666, and commanded a ship in 1672; but subsequently joined the army. He was lord chamberlain to James II., and a cabinet-councillor under William III., who in 1694 made him Marquis of Normanby. Anne raised him to the dignities of Duke of Normanby and Duke of Buckinghamshire (1703); but for his opposition to Godolphin and Marlborough he lost all his offices. After 1710 under the Tory régime he was lord steward of the household and lord president till the death of Anne, when he lost all power, but intrigued zealously for the restoration of the Stuarts. He wrote two tragedies, a metrical *Essay on Satire*, an *Essay on Poetry* (his principal work), and some smaller poems, all of them much talked of at the time, but of little poetic value. He died 24th February 1721.

Sheffield, JOHN BAKER HOLROYD, EARL OF (1735–1821), is chiefly known as the friend of Gibbon (q.v.) and editor of his miscellaneous works. He wrote numerous pamphlets on the slave-trade, the corn laws, the navigation laws, and on commercial and agricultural questions.

Sheikh (Arab., 'elder,' 'aged person'), a title applied to the chieftain of an Arab tribe, to the principal preacher in a Mohammedan mosque, to the head of a religious order, and to a learned man or a reputed saint of Islam. The Sheikh ul-Islam at Constantinople is the head of the Mohammedan church; he is possessed of very great influence and power (see MUFTI). Sheikh al-Jebel (Old Man of the Mountain) was the name of the chief of the Assassins (q.v.).

Sheil, RICHARD LALOR, Irish patriot and orator, was born at Drumdowney, County Tipperary, 17th August 1791, son of a prosperous Cadiz merchant, who had returned to Ireland about the time that the most odious of the Catholic disabilities began to be relaxed. He passed his earliest years at his father's estate of Bellevue near Waterford, and in due time went to school, first to Kensington, then to Stonyhurst, whence he passed in 1807 to Trinity College, Dublin. Soon after this his father failed, but young Sheil was enabled through the help of friends to graduate B.A. in July 1811, and to enter Lincoln's Inn in November of the same year. He was called to the Irish bar in Hilary term, 1814. The next few years he devoted to literature, producing a series of plays, most of which proved successful in Dublin or London: *Adelaide, or The Emigrants* (1814); *The Apostate* (1817); *Bellamira* (1818); *Evadne*, partly based on Shirley's *Traitor* (1819); *The Huguenot* (1819); *Montoni* (1820); and an adaptation of Massinger's play, *The Forgotten Dowry* (1824). His *Sketches of the Irish Bar*, written in conjunction with the younger Curran, appeared during 1822 in the pages of the *New Monthly Magazine* (2 vols. 1855). In 1823 Sheil joined O'Connell's Catholic Association, which was dissolved in 1825, and throughout gave the great tribune a loyal but an independent support. After the Lords threw out the Catholic Relief Bill (May 1825) he aided his chief in forming the New Catholic Association, and throughout the course of the agitation he devoted enormous labour to the preparation of those ornate and impassioned speeches, which, despite his shrill voice and feeble gestures, had often a magical effect on his audience, and many of which remain to posterity among the masterpieces of English oratory. After Catholic emancipation was gained in 1829 Sheil devoted much more of his time than before to his profession. He was returned to parliament for Milborne Port, Dorset, a pocket-borough of Lord Anglesea's, and at the dissolution of 1831 for Louth, and later he sat for Tipperary and Dungarvan. A charge brought against his honour in 1834 by Lord Althorp, that he had in private supported the Coercion Bill of 1833 while publicly opposing it, was unanimously rebutted by a Committee of Privileges. After the defeat of Repeal in 1834, which years later he described as 'a splendid phantom,' Sheil mostly supported the Whigs, and in 1838 received a commissionership of Greenwich Hospital. In August 1839 under Melbourne he became vice-president of the Board of Trade, and a privy-councillor—the first Catholic to gain that honour. Under Lord John Russell in 1846 he was appointed Master of the Mint, and in 1850 British minister at Florence. Here his constitution, enfeebled by gout, sank under the shock of the sudden death of his stepson, May 25, 1851.

See his *Memoirs*, by W. Torrens McCullagh (2 vols. 1855). His *Speeches*, with a memoir by T. MacNevin, were published in 1845; the *Speeches, Legal and Political*, edited by M. W. Savage, in 1855 (2 vols.).

Shekarry (also spelt *shikarry, shikaree, chickary;* Hind. *shikári*), an Anglo-Indian word for 'hunter,' 'sportsman,' familiar to English readers from the books on sport in India by 'The old Shekarry,' Major H. A. Leveson (1828–75).

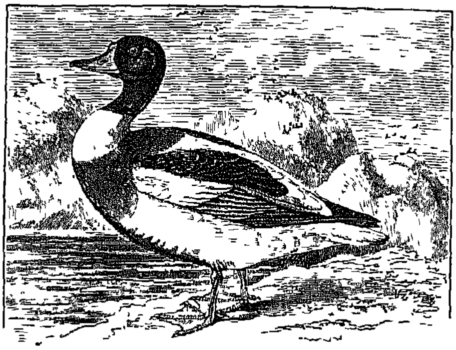
Shekel (Heb., from *shakal*, 'to weigh'), originally a certain standard weight in use among the ancient Hebrews, by which the value of metals, metal vessels, and other things was fixed. Gradually it became a normal piece of money, both in gold and silver, marked in some way or other as a coin, although not stamped. The gifts to the sanctuary, the fines, the taxes, the prices of merchandise are all reckoned in the Old Testament by the shekel, not counted but weighed. Three different kinds of gold, silver, and copper shekels are mentioned: the common shekel, the shekel of the sanctuary (probably of double value), and the shekel of royal weight. Besides these there was a half-shekel and a quarter-shekel. The sacred shekel was equal to 20 gerahs ('beans'), and 3000 sacred shekels made a talent. The gold shekel is reckoned approximately to contain 161 Troy grains, the silver shekel 275. During the Babylonian exile the Persian money (*darics*) was used by the captives; nor do the Jews seem to have afterwards used any but the coins of their foreign rulers. It was first under the Maccabees that national money began to be struck. Simon, the 'prince and high-priest,' received, according to 1 Macc. xv. 16, the permission from Antiochus VII. to strike coins in

138 B.C. The emblems are sacred branches, sheaves, flowers, vases, &c., and the legend (in archaic Hebrew) contains the date, the name of the Jewish ruler, and the inscriptions 'Shekel of Israel,' 'Jerusalem the Holy,' 'Redemption of Israel.' The latest coins with Hebrew inscriptions date from the revolution of Bar-cochba under Hadrian. The value of the silver shekel is reckoned to be something over two shillings.

Sheki'nah. See Ark of the Covenant.

Shelburne, William Petty, Earl of, son of the first earl, and maternal grandson of the famous Sir William Petty (q.v.), was born in Dublin, 20th May 1737, and, after studying at Oxford and serving in Germany, entered the House of Commons for the pocket-borough of Wycombe in 1761, but only sat for a few weeks, the death of his father calling him to the House of Lords. When George Grenville succeeded Bute in 1763 Lord Shelburne was placed at the head of the Board of Trade, and when Chatham formed his second administration in 1766 he became one of the Secretaries of State. Upon the fall of Lord North's ministry in 1782 George III. sent for Shelburne, and proposed to him to form a government. He declined, not being the head of a party, and was sent by the king to the Marquis of Rockingham with an offer of the Treasury, himself to be one of the Secretaries of State. It soon appeared that Shelburne was not so much the colleague as the rival of Lord Rockingham, the chosen minister of the court, and the head of a separate party in the cabinet. Upon Rockingham's death in the following July the king sent at once for Shelburne, and offered him the Treasury, which he accepted without consulting his colleagues. Fox thereupon resigned, and Shelburne introduced William Pitt, then only twenty-three, into office as his Chancellor of the Exchequer. Shelburne's ministry, on the occasion of the king's announcement of his determination to concede the independence of the American colonies, found itself outvoted by the coalition between Fox and Lord North (February 1783). He resigned, and the coalition ministry took his place, but soon broke up. The nation expected that the king on this event would have sent for Shelburne, but William Pitt received the splendid prize, and Shelburne was consoled by being made in 1784 Marquis of Lansdowne (q.v.). The rest of his days he spent in retirement, amusing himself by collecting in Lansdowne House a splendid gallery of pictures and a fine library, and with the friendship of Priestley, Jeremy Bentham, Sir S. Romilly, Mirabeau, Dumont, and others. He died at Bowood Park, Wiltshire, 7th May 1805. See *Life of Shelburne*, by his great-grandson Lord Edmund Fitzmaurice (3 vols. 1875-76), in which he is shown to have been an advocate of reform, free trade, and Catholic emancipation.

Sheldrake (*Tadorna*), a genus of birds of the Duck family Anatidæ, having the hind-toe free. The Common Sheldrake (*T. cornuta* or *vulpanser*) is one of the most remarkable of all the duck tribe for its size and the beauty of its plumage. It is fully 2 feet long. The head and neck are dark glossy green; below this is a collar of white, and lower still a collar of rich chestnut extending over part of the back; the rest of the back is white; the middle of the under-parts is black; the wing speculum green, the primaries and part of the secondaries black; the bill and frontal knob bright carmine; the legs, feet, and webs flesh pink. The female is rather smaller and duller, and has no frontal knob. The sheldrake is confined to salt water, and is found upon flat shores, links, and sand-bars on various parts of the coasts of the British Isles. It is abundant in Sweden, Denmark, the Baltic, and Norway; it is a winter visitor to the Mediterranean, but resident in the Black Sea and the Caspian; it is found in Asia in salt lakes, and as far as Japan. It breeds in burrows made by rabbits and foxes in sand-dunes (hence the name Burrow Duck by which it is sometimes called), or it may make its own burrows. In some sandy islands off the coast of Jutland burrows are made by the inhabitants, who protect the birds for the sake of their eggs and down. The food consists of small molluscs, sand-hoppers, and sea-weed. The flesh is coarse and unpalatable. The note of the male is a shrill whistle; the female utters a harsh bark. The Ruddy Sheldrake (*T. rutila* or *casarca*) is rare as a British bird, and not common anywhere north of the Alps and Carpathians. It is not uncommon in Spain and various parts of North Africa. It is more abundant in the Black Sea area, southern Russia, and the elevated parts of Asia as far as China and Japan. In India, where it is known as the Brahminy Duck, it is very common during the cold season. Four other species are found respectively in South Africa, the Malay Archipelago, Australia, and New Zealand. The name is doubtless derived from *shield*, from the markings on the plumage. Other names are Skeel-duck, Skeeling-goose, Sly-goose, St George's Duck, and Bargander.



Common Sheldrake (*Tadorna vulpanser*).

Shell, a term applied to the hard outer covering or skeleton of many animals, to the internal skeleton of some invertebrates, and to the outer covering of the eggs of various animals. Shells differ so much from one another in structure and chemical composition that a small piece often serves to distinguish not only the family or the genus, but even the species to which an animal belongs. In the class Protozoa, which consists of unicellular animals usually of microscopic size, the shell is very diversified in form and composition, being formed of calcium carbonate, as is typically seen in Foraminifera; flint, as in many Heliozoa and Foraminifera; acanthin, in some Radiolaria; and chitin, as in some Foraminifera. In the Cœlenterata (Sponges, Corals, &c.) the shell may be either continuous or more or less interrupted or formed of spicules or granules; and it may be composed of salts of calcium and magnesium, flint (silica), or 'horny' or chitinoid material. Among the Echinodermata the skin becomes calcified so as to form generally a very complete skeleton. The shell of a starfish or of a sea-urchin presents the appearance seen in fig. 1, which shows

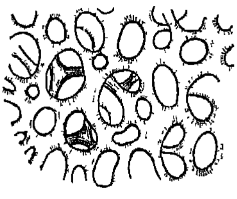


Fig. 1.—Shell of Echinoderm, magnified.

the calcified areolar tissue. In the Mollusca, including the Brachiopoda, a shell, which is closely associated with the breathing organ, is usually present, and appears in the embryo as a growth from a special gland. Its further development depends on the mantle. It grows in superficial extent at the edge of the mantle, and increases in thickness by growth from the surface of the mantle already covered. It is thus essentially a cuticular structure. It may be univalve or bivalve; in only one genus (Chiton) is it composed of several pieces. A section of the shell of the fresh-water mussel (fig. 2) shows (*a*) the thin, horny, uncalcified outer layer which is formed by the thickened edge of the mantle, and is the first to be deposited; (*b*) the middle layer, consisting of numerous calcified polygonal prisms placed side by side, slightly obliquely to the surface of the shell; (*c*) the nacreous or pearly inner layer, finely granulated and traversed by delicate striæ. The calcium carbonate, to which the hardness of the shell is due, may be dissolved away, leaving the organic basis. In the Mollusca shells are distinguished according to their texture as porcellanous, nacreous, and fibrous. In composition they usually consist of carbonate of lime (in the form of calcite, less commonly of aragonite). Some Cephalopods develop an internal calcareous shell. In Arthropoda (Crustaceans, Insects, &c.) the shell is composed of a firm, coloured, lamellated, nearly structureless layer of chitin, with or without an interstitial calcareous deposit, pierced by many pores and by processes of the skin, and shed and renewed periodically. A section of the hard shell of a crayfish (fig. 3) shows (*a*) an outer structureless resistant cuticle; (*b*) a pigmented layer consisting of fine plates parallel to the surface, alternately more or less refractile, and traversed by small vertical pores; (*c*) a thick non-pigmented calcified layer, whose pores are continuous with those of the second layer, and whose lamellæ gradually merge into (*d*) a thin layer of delicate non-calcified lamellæ with a few vertical pores. The organic substratum is chitinoid, and the calcareous matter is chiefly calcium carbonate, and to a much less extent calcium phosphate.

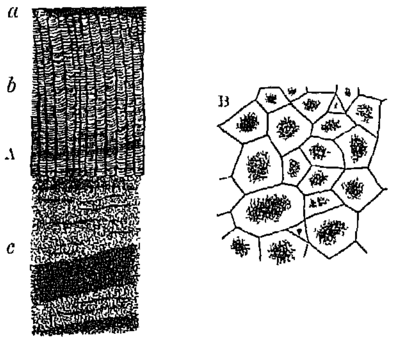

Fig. 2.—Shell of Fresh-water Mussel, magnified:
A, section at right angles to the long axis of the shell; *a*, outer, *b*, middle; *c*, inner layers. B, end view of the prisms of the middle layer.

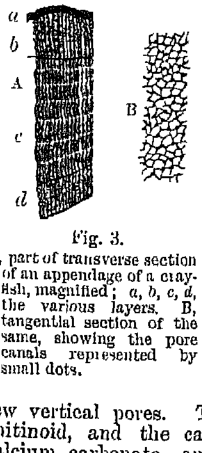

Fig. 3.
A, part of transverse section of an appendage of a crayfish, magnified; *a*, *b*, *c*, *d*, the various layers. B, tangential section of the same, showing the pore canals represented by small dots.

For an account of the structure of shells and the literature on the subject, see Rolleston's *Forms of Animal Life* (2d ed.); Carpenter's *Microscope and its Revelations*; and Quekett's *Lectures on Histology* (vol. ii.), in which there are many excellent drawings. See Bivalves, Conchology, Egg, Foraminifera, Iridescence, Mollusca, Mother of Pearl, Nacre, &c.

Shell, a hollow projectile containing a bursting charge of gunpowder or other explosive ignited at the required instant by means of either time or percussion *Fuses* (q.v.). Originally shells were made of cast-iron, spherical in form, filled with powder, and fired only from Mortars (q.v.) or Howitzers (q.v.) with time fuses. They were called *Bombs* (q.v.) at first, and afterwards *common shells.* A smaller kind were thrown by hand and called *hand-grenades.* Shells appear to have been first used by the sultan of Gujarat in 1480; they were in general use about the middle of the 17th century.

But the introduction of *Shrapnel* shell (so called from the inventor, Colonel Henry Shrapnel, R.A.; died 1842) during the Peninsular war led to the employment of this projectile first with specially manufactured shell-guns, and then, as at present, with all guns of whatever construction. *Shrapnel shells* have thinner walls than *common,* and, instead of powder, are filled with bullets and a small bursting charge just strong enough to open them without disturbing the flight of the bullets. The latter then spread over a considerable area with the velocity which the shell had at the moment of bursting. These projectiles are generally burst by time fuses at least 100 yards in front of and some 50 feet above the target, so that what is called the *cone of dispersion* of the bullets may be as favourably placed as possible. They are essentially man-killing projectiles, in contradistinction to *common shells,* which are chiefly useful for destroying *matériel.*

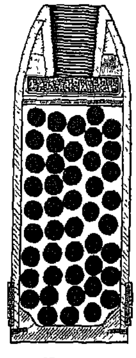

Fig. 1.
Shrapnel Shell.

The original Shrapnel shell was of course spherical for use with smooth-bore guns. It was improved by the introduction of a *diaphragm* to separate the bursting charge from the bullets. When rifled guns and elongated projectiles came into vogue it was found that the ricochet of a solid shot was so erratic that it could not, like the old round shot, have any useful effect, and solid shot gradually ceased to be used, Shrapnel and common shell and case-shot being the artillery projectiles retained.

The Armstrong *Segment* shell (a sort of Shrapnel) is filled with iron segments built up inside it instead of bullets. It was found to give poor results owing to the spin of the shell due to the rifling dispersing the segments on bursting. The German and Swiss *Ring shell* is somewhat similar, having rings of iron built up inside it round the bursting charge; but it is a substitute for common shell, not for Shrapnel.

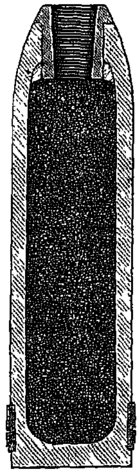

Fig. 2.
Common Shell.

Until quite recently Shrapnel shell found no favour with foreign nations, but by 1892 they had all followed the example set by Great Britain in adopting it. Fig. 1 is a section of modern British steel Shrapnel, with soft metal driving-band at base to give rotation, instead of the metal studs or lead-coating formerly used for that purpose. The bursting charge is at the base of the fuse-hole, and the head is filled with wood. Fig. 2 is the section of a common shell. Shells of all sizes are constructed on the same principles.

Palliser's shells have sharp-pointed heads, no fuse-holes, and very thick walls. They are cast head downwards in thick metal moulds. Their heads are thus chilled, and become hard enough to pierce ship's armour. In passing through the armour the bursting charge is exploded, so that no fuse is needed.

Common shells are now being charged with high explosives in France and Germany. The French use cresylite, a compound of cresol as melinite is of phenol, each being a product of gas-tar; the Germans use gun-cotton. The destructive effect of such bursting charges is of course much more than that of an equal amount of gunpowder. At CANNON will be found more information about Shells, and an illustration of a Whitworth forged shell; see also CASE-SHOT, GRENADE, PALLISER, &c.

Shelley, PERCY BYSSHE, one of the greatest of English poets, was born on 4th August 1792, at Field Place, near Horsham, Sussex, the eldest child of Timothy Shelley and his wife Elizabeth, daughter of Charles Pilfold of Effingham, Surrey. The family was old and honourable. Bysshe Shelley, the poet's grandfather, married two heiresses, acquired a great property, and in 1806 received a baronetcy; in 1815 he died. Percy was a boy of much sensibility, quick imagination, and generous heart; physically of a refined type of beauty, blue-eyed, golden-haired. At ten years old he became a pupil of Dr Greenlaw's at Sion House School, Isleworth, where he made some progress in classics, listened with delight to lectures on natural science, and endured much rough handling from his schoolfellows. In 1804 he passed to Eton, where Dr Goodall was then head-master. He continued his study of the classics, read eagerly Lucretius and Pliny, became a disciple of the 18th-century sceptical and revolutionary writers, pored over Godwin's *Political Justice,* filled his imagination with the wonders of modern science, resisted the system of school-fagging, and held aloof from the throng of the schoolboys, who in turn made him the object of systematic persecution. While still at Eton he wrote a crude romance, in the manner of M. G. Lewis, which was published with the title *Zastrozzi* in April 1810. Before the close of the year a second romance, *St Irvyne, or the Rosicrucian,* appeared; it is as absurd as its predecessor in its sentimental extravagance, its pseudo-passion, and mock sublimity. He assisted his cousin Thomas Medwin in a long poem on the subject of *The Wandering Jew* (1810), and issued with some fellow-rhymer a volume of verse (now known only through reviews), *Original Poetry by Victor and Cazire.* Possibly his collaborator was his cousin Harriet Grove, whom Shelley loved with a boy's passion. Her parents, alarmed by Shelley's religious scepticism, put a stop to the correspondence between the cousins. In April 1810 Shelley matriculated at University College, Oxford, and in Michaelmas term entered on residence. His chief friend was a student from Durham, Thomas Jefferson Hogg, who has left a most vivid account of Shelley's Oxford life. Hogg was shrewd, sarcastic, unimpassioned, and withal a genuine lover of literature. He aided Shelley in putting forth a slender volume of poems, originally written by Shelley with a serious intention, now retouched with a view to burlesque—*Posthumous Fragments of Margaret Nicholson*—the pretended authoress being a mad washerwoman who had attempted the life of the king. In February 1811 a small pamphlet by Shelley, entitled *The Necessity of Atheism,* was printed. When it was offered for sale in Oxford, the college authorities conceived it their duty to interfere; Shelley and Hogg were interrogated respecting its authorship, and having refused to reply, were expelled from University College (March 25, 1811) for contumacy and for declining to disavow the pamphlet. For a time the friends lived together in London lodgings; then Hogg departed to the country and Shelley remained alone. In his solitude he found some pleasure in the society of a schoolfellow of his sisters at Clapham, Harriet Westbrook, a fresh and pretty girl of sixteen, daughter of a retired coffee-house keeper. She moved under the tutelage of an unmarried sister nearly twice her own age. When summer came Shelley was with cousins in Wales; letters reached him from Harriet in London complaining of domestic persecution, and speaking of suicide as a possible means of escape; a letter followed in which she threw herself on Shelley's protection, and proposed to fly with him from her home. Shelley hastened to see her, but at the same time assured a cousin that he did not love Harriet, though he was prepared to devote himself to her through a sentiment of chivalry. On meeting him she avowed her passion, and he left her with a promise that if she summoned him he would come at her call and make her his. The summons came speedily; Shelley and Harriet, aged nineteen and sixteen, took coach for Edinburgh, and were there formally united as man and wife on 28th August 1811. He assured his bride that, in accordance with principles which he firmly held, the union of man and wife might be dissolved as soon as ever it ceased to contribute to their mutual happiness.

Copyright 1892 in U.S. by J. B. Lippincott Company.

Coming from Edinburgh to York, where Hogg resided, the young married pair were joined by Eliza Westbrook, the elder sister. Ill conduct of Hogg towards Harriet caused a temporary alienation between the friends. The Shelleys with Eliza moved to Keswick, where Southey's presence was an attraction. Southey was kind and helpful, but his lack of revolutionary ardour and his indifference to metaphysical speculation displeased Shelley. The young enthusiast found a monitor more to his liking in Godwin, with whom he now corresponded as a disciple with a master. To apply at once his ideas of reforming the world he resolved to visit Ireland, and there advocate Catholic emancipation and Repeal of the Union. On reaching Dublin he printed and scattered abroad an *Address to the Irish People,* written at Keswick. This was soon followed by a second pamphlet, *Proposals for an Association of Philanthropists.* He spoke at a large public meeting from the same platform with O'Connell, and made the acquaintance of Curran. Discouraged by the small results of his efforts, and yielding to Godwin's advice, he left Ireland (April 4, 1812), and after some wanderings in Wales found rest in a cottage at Lynmouth, then a lonely fishing-village. Here he received as a visitor Miss Hitchener, a Sussex schoolmistress, whom both before and for a time after his marriage he had idealised into all that is most heroic and exalted in womanhood, and with whom he was ere long more than disenchanted. He wrote a vigorous pamphlet on behalf of liberty of printing—the *Letter to Lord Ellenborough*—amused himself with circulating, by means of bottles and boxes set afloat in the Channel and by fire-balloon, copies of his satirical poem *The Devil's Walk* and his revolutionary broadsheet *Declaration of Rights,* and was at work on his *Queen Mab.* His servant, having been found posting up at Barnstaple the offensive broadsheet, was imprisoned, and Shelley crossed to Wales. He took up his abode at Tremadoc, where he was much interested in the scheme of a great embankment against the sea. In October he made Godwin's personal acquaintance in London. During the winter he was active in the relief of the suffering poor of Tremadoc, studied history and philosophy, and added to his manuscript poems. On the night of 26th February 1813 an attempt was either really made by some villain to enter the lonely house of Tanyrallt, or Shelley with over-heated fancy conjured up such an outrage. He hastily quitted Tremadoc, and, after an excursion to Dublin, Cork, and Killarney, once again settled in London. In June 1813 his wife gave birth to a daughter who was named Ianthe (married to Mr Esdaile, died 1876). On Harriet's recovery some stay was made at Bracknell in Berkshire. *Queen Mab* was printed for private distribution, its religious and political views being considered too hostile to received opinions to admit of public circulation. The poem sets forth Shelley's youthful conceptions of the past history of humanity, its present evils, and future progress. It is often crude, often rhetorical, yet there is more than a promise of poetical power in certain passages. In the autumn (1813)—perhaps to obtain time to settle with creditors—Shelley and his household went northward to the English Lakes, and thence to Edinburgh, but before the new year opened he was settled at Windsor. About this time he wrote a prose dialogue (published 1814), *A Refutation of Deism*, designed to prove that there is no *via media* between Christianity and Atheism.

In March 1814 Shelley went through the ceremony of marriage with Harriet according to the rites of the English Church, probably to set at rest any doubts of the validity of the Scotch marriage. He was endeavouring to raise large sums of money on Godwin's behalf, and the marriage may have been considered advisable to render certain the legitimacy of a future son and heir. Four months later he had separated from his wife for ever. Their early married happiness had become hopelessly clouded; an attempt at reconciliation made by Shelley in May was rejected. Harriet withdrew to Bath. It was stated by Miss Clairmont, the daughter of Godwin's second wife, that Shelley declared in July 1814 that Harriet had yielded herself to a certain Major Ryan, and Godwin in 1817 stated in writing that he had evidence independent of Shelley of her unfaithfulness before Shelley left her. No such evidence is in our possession to-day, and statements to the contrary were made by Harriet herself and by several persons who knew her well. The division between husband and wife, whatever its causes, was deep. Shelley had become suddenly and passionately enamoured of Godwin's daughter, Mary, a girl of fine intellect and vigorous character. Having informed Harriet of his resolve to leave her finally, and having made arrangements for her material comfort, he took flight to the Continent with Mary Godwin on 28th July 1814. Miss Clairmont accompanied the fugitives. Shelley was inexperienced enough to suppose that Harriet could still regard him as a considerate friend, though no longer her husband.

After a journey across France and a short stay in Switzerland, Shelley and his companions returned by the Rhine to England. The last months of 1814 were full of vexation caused by debts and duns. But in January 1815 Shelley's grandfather died, and by an arrangement with his father he obtained an income of a thousand a year. His health unhappily showed the effects of the previous year's strain and excitement. He sought rest and refreshment in Devon, and in August found a home at Bishopsgate, on the edge of Windsor Forest. In the autumn of 1815 *Alastor*, his first really admirable poem, was written. It tells of the ruin of an idealist who, pining for absolute love and beauty, shuns human society; its visionary landscapes have the largeness and ideality characteristic of Shelley. In January 1816 Mary gave birth to a son, who was named after her father; but Godwin still held aloof. It was decided to try life upon the Continent, and in May Shelley and Mary travelled through France to Geneva. Miss Clairmont, whose intrigue with Byron was unknown to Shelley and Mary, accompanied them. On the shores of the Lake of Geneva a meeting took place between Byron and Shelley. They rowed and sailed together on the lake, and Shelley in company with Mary made an excursion to Chamouni. In the poem *Mont Blanc* and the *Hymn to Intellectual Beauty* we find a poetic record of the impressions of these memorable days.

In September they were once more in England. The suicide, following a state of deep depression, of Fanny, the half-sister of Mary (see GODWIN, WILLIAM), gave Shelley a great shock, and this disaster was soon followed by the death of Harriet Shelley. For some time past Shelley had in vain inquired for her. She had formed an irregular connection with one who, it is believed, deserted her. On 10th December her body was discovered in the Serpentine; had she lived she would soon have given birth to a child. It was another severe shock to Shelley, but he always maintained that he himself was 'innocent of ill, either done or intended.' Free now to make Mary his lawful wife, he at once celebrated his marriage (30th December 1816). A long Chancery suit followed, Shelley seeking to obtain possession of his daughter Ianthe and his son Charles (born November 1814—died 1826), the Westbrooks resisting. At length Lord Eldon gave judgment which compromised the matter; Shelley's opinions being such as led to immoral and illegal conduct, he was disqualified for bringing up his children, but he might appoint caretakers and tutors to be approved by the court. The blow was deeply felt by Shelley. While the Chancery affair was proceeding he was cheered by the friendship of Leigh Hunt and of Horace Smith. His home was at Marlow on the Thames, and here he wrote fragments of his *Prince Athanase*, a portion of *Rosalind and Helen*, and his long narrative poem *Laon and Cythna*, designed to sustain men's hopes in ideals of freedom and progress during days of political reaction. When some few copies of *Laon and Cythna* had been issued the publisher withdrew it from circulation, and induced Shelley to alter certain lines and phrases which might give offence. As thus revised the poem was issued with a new title, *The Revolt of Islam*. During his residence at Marlow Shelley worked earnestly and systematically in the relief of the poor. He printed two pamphlets, *A Proposal for Putting Reform to the Vote*, by 'The Hermit of Marlow,' and *An Address to the People on the Death of the Princess Charlotte*. In the spring of 1818 it was feared that he was threatened with pulmonary disease. He decided to seek a southern climate, and in April, with Mary, little William, an infant daughter Clara (born 2d September 1817), Miss Clairmont and her child Allegra (Byron's daughter), he left England for Italy, never again to see his native land.

In the summer of 1818, at the Baths of Lucca, Shelley completed his *Rosalind and Helen*, and made his translation of Plato's *Banquet*. Grief came with the autumn; little Clara died on 24th September at Venice, where Shelley had been renewing his companionship with Byron. Memorials of this visit to Venice, with an idealised presentation of Byron, will be found in the admirable poem

Julian and Maddalo. He contemplated a tragedy of *Tasso*, but this was set aside in favour of his great lyrical drama *Prometheus Unbound*, the first act of which was written at Este, September–October 1818. Seeking a warmer climate for the winter, he journeyed to Rome, and thence to Naples. His letters descriptive of Southern Italy are full of radiance and luminous beauty. In the spring (1819) he was again in Rome, and found great delight in its classical sculpture and architectural remains. Among the ruins of the Baths of Caracalla he wrote the second and third acts of *Prometheus.* The fourth act—not originally conceived as part of the poem—was added before the close of the year at Florence. On 7th June 1819 Shelley's beloved son William died at Rome. The afflicted parents sought the neighbourhood of kind friends near Leghorn, and here—at the Villa Valsovano—Shelley wrote the greater part of his dark and pathetic tragedy *The Cenci.* At Leghorn the first edition was printed in quarto. The other works of this memorable year were written at Florence—a prose treatise called *A Philosophical View of Reform* (still unpublished in its entirety); a poetical appeal to his countrymen on the occasion of the 'Peterloo' affair, entitled *The Mask of Anarchy;* a grotesque satire suggested by the supposed failure of Wordsworth's poetic powers under the blight of Toryism—*Peter Bell the Third;* a translation of *The Cyclops* of Euripides; and in addition to these some of his noblest lyrical poems, among them the magnificent *Ode to the West Wind.*

On 12th November 1819 a son was born to comfort his father and mother, Percy Florence (died 5th December 1889). The climate of Florence was found trying, and in January the Shelley household moved to Pisa, where was spent the greater part of the poet's remaining days. The year 1820 was less productive than 1819. The charming poetical *Letter to Maria Gisborne*, a spirited translation of the Homeric *Hymn to Mercury*, the brilliant fantasy of *The Witch of Atlas*, the satirical drama *Œdipus Tyrannus or Swellfoot the Tyrant*, which deals not very happily with the affair of Queen Caroline, are the chief writings of 1820. As the year was closing the Shelleys made the acquaintance of a beautiful girl, Emilia Viviani, who was confined in the convent of St Anna. To Shelley's imagination for a brief time she became the incarnation, as it were, of all that is most perfect, all that is most radiant in the universe. At such a moment he wrote his *Epipsychidion*, which is rather a homage to the ideal as seen in womanhood than a poem addressed to an individual woman. It was followed by a remarkable piece of prose—the critical study entitled *A Defence of Poetry.*

A small circle of interesting friends had gathered about Shelley at Pisa. Among these were Edward Williams, a young lieutenant of dragoons, and his wife Jane, to whom many of Shelley's latest lyrics were addressed. In the summer of 1821 the Shelleys and Williamses had much pleasant intercourse at the Baths of San Giuliano. The elegy *Adonais*, suggested by the death of Keats, was here written; it is Shelley's most finished piece of art. In the late summer or autumn he swiftly composed his *Hellas*, a lyrical drama suggested by passing events in Greece. Early next year Byron was settled in Pisa, and Shelley had also an interesting new companion in Trelawny, a young man of ardent and romantic temper. Shelley worked somewhat tentatively at his unfinished historical drama *Charles I.* His last great poem, also unfinished, *The Triumph of Life*, was written in his boat near Casa Magni, a lonely house on the eastern side of the Bay of Spezzia, occupied as a summer residence by the Shelleys, together with Edward and Jane Williams.

On 19th June Shelley heard of the arrival in Italy of Leigh Hunt and his family. He and Williams, some days later, set sail for Leghorn. The meeting with Hunt was full of joy and hope. On Monday, 8th July, Shelley and Williams left the port of Leghorn with a favourable breeze; the boat was observed at ten miles distance; then it was lost in sudden storm and mist. Dreadful uncertainty for a time came upon the two widowed women at Casa Magni. On 19th July the bodies were found upon the shore near Via Reggio. By special permission they were consumed by fire in the presence of Trelawny, Hunt, and Byron. The ashes of Shelley were placed in a casket, and were afterwards interred in the Protestant burial-ground at Rome.

In person Shelley was tall and slight, and if not of exact formal beauty of face had a countenance full of spiritual beauty, radiant with its luminous blue eyes. His portrait, painted in Rome by Miss Curran, is the only likeness of Shelley in manhood. His poetry is inspired by an ardent passion for truth, an ardent love of humanity; it expresses desires and regrets with peculiar intensity, but also sets forth a somewhat stoical ideal of self-possession, as if to balance the excessive sensitiveness of its author. The earlier poetry is aggressive and doctrinaire, embodying the views and visions of Godwin's philosophy; the later is more purely emotional. Shelley's creed, which passed at an early stage from deism to atheism, rested in his mature years on a spiritual conception of the universe.

Mary Wollstonecraft Shelley, daughter of William Godwin and Mary Wollstonecraft, and wife of the poet Shelley, was born August 30, 1797. Her life from 1814 to 1822 was bound up with that of Shelley. Her first and most impressive novel, *Frankenstein*, had its origin in a proposal of Byron's, made in 1816 at his villa on the Lake of Geneva, that Mary and Shelley, Polidori (Byron's young physician), and Byron himself should write each a ghost story. *Frankenstein* (q.v.) was published in 1818. The influence of Godwin's romances is apparent throughout. Her second tale, *Valperga, or the Life and Adventures of Castruccio, Prince of Lucca* (1823), is a historical romance of mediæval Italy. In 1823 she returned to England with her son. Her husband's father, in granting her an allowance, insisted on the suppression of the volume of Shelley's *Posthumous Poems*, edited by her; and she was obliged to submit. *The Last Man* (1826), a romance of the ruin of human society by pestilence, fails to attain sublimity, but we can trace in it with interest idealised portraits of some of the illustrious persons most intimately known to her. In *Lodore* (1835) we read under a disguise the story of Shelley's alienation from his first wife. Her last novel, *Falkner*, appeared in 1837. She published several short tales in the annuals, some of which have been collected and edited by Dr Garnett. Of her occasional pieces of verse the most remarkable is *The Choice.* She wrote also many of the lives of Italian and Spanish literary men in Lardner's *Cabinet Cyclopædia.* Her *Journal of a Six Weeks' Tour* (partly by Shelley) tells of the excursion to Switzerland in 1814; *Rambles in Germany and Italy* describes a series of tours in her later years. She will be remembered by *Frankenstein* and her admirable notes—in large part biographical—to her husband's poems. Those who knew her intimately valued Mary Shelley for her nobility of character, even more than for her fine intellect. She died February 21, 1851, and was buried in Bournemouth.

The best edition of Shelley's works in verse and prose is Mr H. B. Forman's (8 vols. 1876–80). Mr Forman has also given an admirable text of the poetical works in two volumes. Mr Rossetti's edition of the poetical works is of great value. The most complete one-volume edition of the poetical works is that by the present writer (Professor Dowden), who has also written the fullest and most exact Life of Shelley (2 vols. 1886). Mrs Julian Marshall has written a valuable Life of Mary Wollstonecraft Shelley (2 vols. 1889); and there is a short Life of her by Mrs W. M. Rossetti. Short lives of Shelley have been written by Mr Symonds, Mr Rossetti, Mr Salt, and Mr W. Sharp, and by the poet's daughter-in-law, Lady Shelley. Hogg's Life of Shelley is excellent for the months at Oxford. Trelawny's *Records* gives a vivid picture of Shelley during his last days. Dr Garnett's *Relics of Shelley* gave for the first time many pieces recovered from MSS. The same careful editor has superintended an admirable selection from Shelley's *Letters* (1882). Mr Forman's *Shelley Bibliography* (1882) is full and accurate. The publications of the 'Shelley Society' include reprints of several rare editions. A *Shelley Concordance* is promised by Mr F. S. Ellis.

Shell-fish, a popular term for many aquatic animals not fishes (in the sense in which the word 'fish' is now understood); especially oysters, clams and all molluscs, and crustaceans such as crabs and lobsters.

Shell-lac. See LAC.

Shells. See SHELL.

Shell-sand. Sand consisting in great part of fragments of shells, and often containing a small proportion of organic matter, is a very useful manure, particularly for clay soils, heavy loams, and newly-reclaimed bogs. It is also advantageously applied to any soil deficient in lime. It neutralises the organic acids which abound in peat, and forms with them compounds which serve as food for plants. Great deposits of shell-sand are found on the coasts of Devonshire and Cornwall, and are of much value in the agriculture of that district. Shell-sand is also found on many other parts of the British coast, and nowhere more abundantly than in the Outer Hebrides. The sand of many parts of the coast being mostly siliceous is incapable of the same use. Shell-sand is much used as a manure in some of the maritime districts of France, as Bretagne and Normandy.

Shelta, or SHELRŪ, is a secret jargon of great antiquity spoken by Irish tinkers, beggars, and pipers, the descendants of the ancient ceards and bards. The word Shelrū is a perversion of the Irish *béulra*, 'language.' Shelta is otherwise known as 'Cainnt cheard,' 'Minkur-tharal,' 'Gam (or Gamoch) cant,' 'Bog-latin,' and 'Béarl' eagair.' For use of last name see *Gaelic Dictionary of the Highland Society* (1828), i. 113: '"Beurl' eagair" or "Laidionn nan ceard," the gibberish of tinkers: figulorum stribligo; dialectus qua utuntur ollarum sartores circumforanei;' also i. 548: 'Gibberish: mendicorum et nebulonum ex compacto sermo, barbaries.' Béarla eagair (i.e. 'vernacular') thus used must not be confounded with Béarlagair na saor (mason's jargon), a few words of which are given by MacElligott (*Dublin Gaelic Society*, 1808). The earliest specimens of this idiom, collected (1877-80) by Mr C. G. Leland from an English vagrant in North Wales and an Irish tinker in Philadelphia, are published in *The Gypsies*, pp. 354-372. The investigation of Shelta was continued by Mr D. MacRitchie in the *Journal of the Gypsy Lore Society* (i. 350-357), where fresh examples from the Scotch Highlands and south of Ireland subsequently appeared. In the same *Journal* (ii. 204-220) the present writer showed Shelta to be a systematic perversion of the pre-aspirated Gaelic spoken anterior to the 11th century, and Dr Kuno Meyer (ii. 257-266) in an erudite paper on 'The Irish Origin and Antiquity of Shelta' adduced numerous references to this jargon in early Irish MSS. Shelta has been identified by Dr Meyer with the ancient secret language called Ogam, a word probably surviving in the name Gam or Gamoch cant. References to Ogam as a spoken tongue occur in the *Annals of Clonmacnoise* (1328) and in O'Molloy, *Grammatica* (1677), p. 133. Several common Shelta words are found in the *Dúil Laithne* or Book of Latin (cf. 'Laidionn nan ceard;' for Latin = cant, see Pott's *Zigeuner*, i. 8), an Ogam glossary copied by MacFirbis from an old or middle Irish MS. Professor Thurneysen (*Revue Celtique*, vii. 369-375) has shown that many of these Ogam words are formed by substituting for the initial its runic name: thus *manaith* (*D. L.* 137 = Shelta *mŭnni*) is formed from Ir. *maith* by changing *M* into *muin*, the name of the letter; Shelta *nadherum*, 'mother,' being similarly an anagram of *muinathair* (Ir. *mathair*). Shelta words are also fabricated from Irish by reversing or transposing the letters of the original word (e.g. *grē*, 'rise,' Ir. *érg*; *tober*, 'road,' Ir. *bothar*), by changing the initial (e.g. *jŭmnik*, 'Sunday,' Ir. *domnach*), and by the prefix, suffix, or interpolation of arbitrary letters to the Irish word or its anagram (e.g. *gladher*, 'skin,' Ir. *leathar*; *thalosk*, 'day,' Ir. *latha*; *srīgo*, 'king,' Ir. *rig*; *laskon*, 'salt,' Ir. *salann*). Analogous modes of word-disguise are described in the *Amra Choluimchille*, an Irish MS. of the 12th century, and in the *Uraicept na n-Eges* (Primer of the Poets), each of these processes having a recognised name. A few old Irish words are used in Shelta without disguise, as *kūnya*, 'priest,' Ir. *cairneach*, 'druidical priest;' *gyukera*, 'beggar,' Ir. *geocaire*. Shelta borrows its grammar and unimportant words from Irish or English. The following translation of the Lord's Prayer ('Staffara a' Dhalyon') by an old Irish tinker illustrates the hybrid grammar of the Ulster dialect:

Mŭīlsha's gather, swŭrth a mŭnniath, mŭnni-grāūa kradyi dhŭīlsha's mŭnnik. Gra be *grŭdhi'd shedhi* ladhu, as aswŭrth in mŭnniath. Bŭg mŭīlsha thalosk minŭrth goshta dhuria; *gretul our shakū* arafk mŭīlsha getjas *nīdyas grŭdhi gamiath* mulsha. Nijesh solk mwī-il stŭrth gamiath but bug mŭīlsha achim gamiath. Dhī-il the srīdug, thardyūnath and mŭnniath. Gradhum a gradhum.

The tinkers believe Shelta to be an independent language of Pictish origin (*The Gypsies*, p. 371). Mr MacRitchie connects this tradition with the fact that Creenie (Cruithnigh) is a Connaught tinker surname, and Crink (Cruithneach) a nickname for Irish tinkers (Groome, *In Gipsy Tents*, p. 147). Shelta contributes largely to other English and Irish cants. See *ken* and *gage* (vb) in Harman's *Caveat* (1566), *cin* (Shelta, *ken*) in MacElligott's *Berlagar na saer*, and *tobar* in *Rapparee* (Ir. *rapaire*) cant. See, besides the works cited above, a monograph (1892) by the present writer (Mr John Sampson).

Shemakha, a town of Russian Caucasus, 63 miles W. by N. of Baku, with silk manufactures. It was for centuries the capital of the Tartar khans of Shirvan, but was entirely destroyed by Nadir Shah in 1742. Nevertheless it was soon rebuilt, but was overwhelmed by an earthquake in 1859, and a second time in 1872. Pop. (1886) 28,545.

Shemites. See SEMITES.

Shenandoah, (1) a river of Virginia, drains the beautiful and fertile valley between the Blue Ridge and the principal range of the Alleghanies. It rises in two branches, which unite about 85 miles W. of Washington, and runs north-east 170 miles to the Potomac, at Harper's Ferry. In the war of 1861-65 this valley was the scene of numerous battles, was successively occupied by the opposing armies, and finally was carried and laid waste by General Sheridan (q.v.) in 1864-65.—(2) A borough of Pennsylvania, 138 miles by rail NW. of Philadelphia. It has a very large trade in anthracite coal, the output of the neighbouring collieries reaching $2,500,000 in a year. Pop. (chiefly foreign, 1880) 10,147; (1890) 15,944.

Shendy, a town in Lower Nubia, on the right bank of the Nile, 100 miles NNE. below Khartoum, with a trade in salt, wool, carpets, ostrich-feathers, &c., and a pop. of about 5000 (40,000 prior to its destruction by the Egyptians in 1822).

Shenstone, WILLIAM, son of Thomas Shenstone of the Leasowes, Hales Owen, Shropshire, was born there 18th October 1714. In 1732 he was sent to Pembroke College, Oxford, and whilst there devoted himself much to the study of English poetry. In 1737 he published anonymously a small volume of *Poems upon Various Occasions*; in 1741 *The Judgment of Hercules*; and next year *The Schoolmistress*, the work by which he is chiefly remembered. In 1745 he succeeded his father in the estate of the Leasowes, where he thenceforth busied himself with landscape-gardening. Such was his success in beautifying his little domain that it attracted visitors from all quarters, and brought him more fame than his poetry, but at the same time involved him in serious pecuniary embarrassments. He died 11th February 1763. *The Schoolmistress*, which has secured for the 'water-gruel bard' (as Horace Walpole dubbed him) a permanent if humble place among English poets, is written in the Spenserian stanza; and in the contrast between the stateliness of the vehicle and the familiar and homely quality of the subject, with the graphic truth of its treatment, there is a singular source of charm. Shenstone's other works are for the most part quite insignificant; but his *Pastoral Ballad* has touches of exquisite tenderness and truth of sentiment expressed in a simple and appropriate melody.

See Life by Dr Johnson prefixed to the pithy *Essays on Men and Manners* (new ed. 1868) and that by George Gilfillan to an edition of his *Poems* (Edin. 1854).

Sheol. See HELL.

Shephelah. See PALESTINE.

Shepherd of Hermas. See HERMAS.

Shepherd's Dog. See SHEEP-DOG.

Shepherd's Purse (*Capsella Bursa-pastoris*—formerly *Thlaspi*), an annual plant of the natural order Cruciferæ, a most abundant weed in gardens and cornfields in Britain, and remarkable as one of the few plants that are found over almost the whole world without the tropics, adapting themselves to almost all soils and climates. It is a very variable plant, from three inches to two feet in height, with root-leaves more or less pinnatifid, all the leaves more or less toothed, and rough with hairs. The root-leaves spread closely along the ground. The flowers are white and diminutive. The pouch, from which the English name seems to be derived, is laterally compressed and somewhat heart-shaped.

Shepherd's Purse (*Capsella Bursa-pastoris*).

Sheppard, JACK, born at Stepney in 1702, was the son, grandson, and great-grandson of a carpenter, and himself at twelve, after a year and a half's schooling in Bishopsgate workhouse, was apprenticed to a carpenter in Wych Street, Drury Lane. For six years he did well, but, falling then into bad company, in July 1720 he committed the first of many robberies. In the course of 1724 he was four times caught, but as often escaped, on the occasion of his third evasion from Newgate forcing six great doors. The fifth time luck deserted him, and on 18th November he was hanged at Tyburn in the presence, it was said, of 200,000 spectators. Harrison Ainsworth has made him the hero of a novel (1839). See *Celebrated Trials* (vol. iii. 1825).

Sheppey, ISLE OF, a portion of the county of Kent, insulated from the mainland by the Swale, an arm of the estuary of the Medway. It now is 9 miles long and 4 broad. In early times its dimensions were much greater; but the sea has encroached upon, and is gradually eating away, the northern shore, which is lined by cliffs of London clay 60 to 80 feet high. The church of Minster, formerly in the middle of the island, is now close to the north coast. Great numbers of interesting Eocene fossils are found imbedded in the London clay, of which the whole island is composed. In the north of the island corn is grown, but the south districts, which are low, are laid out in grass. Almost the whole of the inhabitants are massed in the seaport of Sheerness (q.v.). In May 1732 Hogarth and four others made 'a five days' peregrination' of the island—their illustrated account of which has been several times published (1781, 1782, 1817, &c.).

Shepton Mallet, an ancient market-town of Somersetshire, 5 miles ESE. of Wells and 15 SSW. of Bath. It has an hexagonal market-cross of 1500, 51 feet high; a church with a splendid timber roof; a grammar-school (1627); and manufactures of silk, velvet, crape, ale. Pop. (1851) 3885; (1891) 5501. See J. E. Farbrother's *Shepton Mallet* (1860).

Sherbet, a beverage much used in Mohammedan countries, where stimulating drinks are forbidden. It consists of the juices of various fruits diluted with water, and sweetened.

Sherborne (A.S., 'clear brook'), a pleasant old-fashioned town of Dorsetshire, in the Vale of Blackmore, on a gentle southern hill-slope above the Yeo, 17 miles N. by W. of Dorchester and 5 E. of Yeovil. In 705 Ina, King of Wessex, made it the seat of a bishopric, with St Aldhelm for first bishop, whose twenty-fifth successor, Hermann, in 1075 transferred the see to Sarum. The noble cruciform minster, measuring 207 by 102 feet, with a tower 114 feet high, was the church of a great Benedictine abbey, founded by Bishop Roger in the first half of the 12th century. It was converted from Norman to Perpendicular after a great fire in 1436, and was restored in 1848-58 at a cost of over £32,000. Noteworthy are the clerestory, vaulting, and choir; and in the retrochoir are the graves of Asser and two of King Alfred's brothers. King Edward's School, comprising remains of the abbey buildings, was founded in 1550, and reorganised in 1871, since when it has risen to be one of the great public schools of England, with a yearly endowment of £800 and 300 boys. Former pupils have been Vice-chancellor Knight-Bruce, the Right Hon. Montague Bernard, Dr J. M. Neale, and Mr Lewis Morris. Sherborne Castle is an Elizabethan mansion, built in 1594 by Raleigh in the grounds of Bishop Roger's Norman castle (*c.* 1125), which, taken by Fairfax in 1645, is now a ruin. Sherborne has also a literary institute

(1859), Bishop Neville's 15th-century hospital, and the Yeatman memorial hospital (1863), with some manufactures of lace, buttons, and silk. Pop. (1861) 5523; (1891) 3741.

Sherbrooke, a city of Quebec, capital of Sherbrooke county, at the junction of the rapid Magog (with falls) and St Francis rivers, 168 miles by rail E. of Montreal, with many busy factories, and 9000 inhabitants.

Sherbrooke, LORD. The Right Hon. Robert Lowe, Viscount Sherbrooke, was born in 1811 at Bingham, Notts, of which parish his father was rector. He was educated at Winchester, and University College, Oxford, of which he became a fellow and tutor. Called to the bar in 1836, he emigrated in 1842, and soon attained a lucrative practice at the Sydney bar; he also took a leading part in the political life of the colony, ultimately as member for Sydney. At home again in 1850, and returned in 1852 for Kidderminster as an independent member with Conservative tendencies, he in 1853 took office under Lord Aberdeen, and in 1855 under Lord Palmerston. In 1859 he was returned for the borough of Calne by the influence of the Marquis of Lansdowne; and he represented London University from 1868 till he went to the Upper House. During 1859-64 he was vice-president of the Education Board (and virtual minister for Education) in the second Palmerston administration, resigning in 1864, and introduced the Revised Code of 1860, with its principle of 'payment by results.' He largely contributed to ensure the rejection of the Whig Reform Bill in 1866. He was, with other 'Adullamites,' offered a post in the Derby government, but he declined to leave the Liberal party, though in 1867 he was still an opponent of all reduction of the suffrage. In 1868 his feud with the Liberal party was forgotten in the strenuous aid he gave the Liberal leaders in carrying the disestablishment of the Irish Church. Accordingly he obtained in Mr Gladstone's Liberal ministry the office of Chancellor of the Exchequer; exchanging it in 1873 for that of Home Secretary. As Chancellor of the Exchequer, his proposal of a tax on matches was very unpopular; but the annual surpluses were large almost beyond example. He exerted himself to keep down the public expenditure; and his curt treatment of all claimants of public money brought odium upon him. In acuteness and cogency of argument he was hardly equalled among the public speakers of his day. As an educational reformer he was an opponent of the pre-eminence allowed to the study of the classics. He was made an LL.D. by Edinburgh in 1867, D.C.L. by Oxford in 1870, and in 1880 went to the Upper House as Viscount Sherbrooke. A volume of *Poems of a Life* was published in 1884.

Shere Ali. See AFGHANISTAN.

Sheridan, PHILIP HENRY, was born in Albany, New York, March 6, 1831, but a few weeks after the arrival of his Irish parents in the New World. After attending a public school in Ohio, to which state the family removed soon after his birth, he was employed for a time as a shop-boy. In July 1848 he was appointed a cadet at West Point, graduated in 1853, and was appointed a brevet second-lieutenant in the Third Infantry. In May 1861 he was a captain in the Thirteenth Infantry, and in December of that year he was made chief quartermaster of the army in south-western Missouri. In April 1862 he became chief quartermaster under General Halleck; but in May he was given a regiment of cavalry (the Second Michigan), and, being now in his proper sphere, did such excellent work that he was soon promoted to the command of a brigade, and then to a division of the Army of the Ohio. In the battle of Perryville (8th October), and still more in the battle of Stone River (Murfreesboro'), which ended on 3d January 1863, and where his division lost over 1600 men, he performed brilliant services, and earned his promotion to major-general of volunteers. He took part in the severe battle of Chickamauga, from which field the Northern army fell back within the defences of Chattanooga, and there, serving now under the immediate command of General Grant, he was engaged in all the operations of the campaign that followed, gaining especial credit for the dash and gallantry with which his division drove the enemy up the slope and over the summit of Mission Ridge. Soon afterwards transferred to Virginia, in April 1864 he was given command of all the cavalry of the Army of the Potomac, took part in the battle of the Wilderness, and made a notable raid (May 9-25) on the Confederate lines of communication with Richmond, advancing to the outer defences of that city, cutting railroads, destroying depôts, and on the 11th defeating the enemy's cavalry at Yellow Tavern with the loss of their commander, General Stuart. In the same month he was first into Cold Harbor, and in June took part in the heavy battle there, and fought a number of cavalry actions. In all these his dash and skill attracted Grant's admiration, and in August he placed Sheridan in command of the Army of the Shenandoah, giving him two cavalry divisions commanded by Generals Torbert and Wilson. The task set him was to drive the Confederates out of the Shenandoah Valley and to close this gate into Pennsylvania and Maryland. In September he attacked the enemy under General Early, drove them through and many miles beyond Winchester, and captured 5000 prisoners and 5 guns; and from Fisher's Hill, where Early halted, he again dislodged him, and pursued him through Harrisonburg and Staunton. These battles made him a brigadier-general in the regular army. But Early's army, being largely reinforced by General Lee, again appeared in the Shenandoah Valley, and on October 19, advancing under cover of fog and darkness, succeeded in surprising the Northern army and driving it back in confusion. Sheridan had been in Washington, and at this time was at Winchester, twenty miles away. Hearing the guns, he put his horse to its speed, and arrived on the field by ten o'clock, waving his hat and shouting to the retreating troops, 'Face the other way, boys; we are going back.' His unexpected appearance restored confidence, the lines were re-formed, and a serious defeat was suddenly converted into a great victory. The enemy's left was soon routed, the rest shared their fate, and the Confederates were again, and finally, driven from the valley, which Sheridan, by Grant's orders, now devastated. For Winchester he was promoted to major-general and received the thanks of congress, and Grant's armies fired a salute of 100 guns in honour of the victory.

Henceforward Sheridan fought always under Grant's direct command, and took an active part in the final battles which led to Lee's surrender at Appomattox Court-house, April 9, 1865. His ability as a general was nowhere better displayed than in the action at Dinwiddie Court-house and the assault of Five Forks in March and April, which drove Lee from Petersburg and Richmond. After the war Sheridan was placed in command of the military division of the Gulf, and later of the department of the Missouri. When Grant became president of the United States General Sherman was made general-in-chief and Sheridan promoted to lieutenant-general. In 1870 the latter visited Europe to witness the conduct of the Franco-

German war, and was with Von Moltke during the battle of Gravelotte. On the retirement of Sherman in 1883 he succeeded him as general-in-chief. In May 1888 Sheridan became seriously ill, and a bill was speedily passed by both Houses of Congress restoring for him the full rank and emoluments of general. He died at his country-house in Nonquitt, Massachusetts, August 5, 1888, leaving a widow and three children. He was buried at Arlington, Virginia, within sight of Washington, where a beautiful monument marks his grave.

Sheridan was the nineteenth general-in-chief of the United States army. He never lost a battle, and the confidence and affection which 'Little Phil,' as they delighted to call him, inspired in his troops may be gauged by the story of Winchester. Among the Northern generals he ranks second only to Grant and Sherman. See his *Personal Memoirs* (2 vols. 1888).

Sheridan, Richard Brinsley Butler, was born in Dublin, 30th September 1751. He was the grandson of Swift's friend, Thomas Sheridan, D.D. (1684–1738), and the second son of Thomas Sheridan (1721–88), a man of established reputation as a teacher of elocution, and the author of a now forgotten *Life of Swift*. His mother, Frances Sheridan, *née* Chamberlaine (1724–66), also had achieved some success in literature, being the author of a novel called *Sidney Biddulph*, and of one or two plays. Richard Sheridan was educated at Harrow, where he does not seem to have distinguished himself much. After leaving school he made his first attempt at literature, in collaboration with a school-friend named Halhed, in the form of a three-act farce called *Jupiter*, the general idea of which bears some resemblance to that afterwards worked out in the *Critic*. It does not, however, appear to have ever been completed. The two friends next attempted a verse translation of the *Epistles of Aristænetus*—a pseudo-classical author of unknown date and doubtful identity—of which the first part was published, but attracted no favourable notice. In 1771 the Sheridans settled at Bath, where they made acquaintance with the family of Linley the composer. A sort of sentimental friendship, ripening into a warmer feeling, appears to have been set up almost immediately between Elizabeth Linley, the eldest daughter—a girl of great beauty and musical talent, popularly known as the Maid of Bath—and Richard Sheridan, which, after various romantic episodes, terminated in a marriage, with the rather reluctant consent of the parents in 1773.

The young couple settled down in London to a life considerably beyond their means. Mrs Sheridan had a fortune in her voice, but her husband would not allow her to use it professionally. He himself now made more serious efforts at dramatic composition—which had always attracted him—and got a play accepted at Covent Garden. On the 17th of January 1775 the *Rivals* was produced for the first time with no great success; but after a slight alteration in the cast the play met with universal approval. Probably it will always remain the most popular of Sheridan's performances. There is nothing in it to strain the understanding or require any education of mind to comprehend. Nor does it contain the least touch of bitterness; vices are not satirised, but only oddities laughed at. Above all, the plot is clear and connected, a point by which the ordinary playgoer is naturally apt to judge. It is not too much to say that in genuine mirthful humour Sheridan has been surpassed by Shakespeare alone; and this quality predominates in the *Rivals*. In the same year appeared the farce called *St Patrick's Day*—a poor performance which Sheridan wrote for the benefit of the Irish actor whose personation of Sir Lucius had saved the *Rivals*—and also the *Duenna*, which received an exaggerated meed of praise, and had a (then) phenomenal run of sixty-three nights. In 1776 Sheridan, with the aid of his father-in-law, Linley, and another friend, bought half the patent of Drury Lane Theatre for £35,000 from Garrick, who was retiring from the stage, and some years later the remaining share for £45,000 from Mr Willoughby Lacy, thus becoming complete owner. His first production here was a purified edition of Vanbrugh's *Relapse*, under the title of a *Trip to Scarborough*, while three months later appeared his greatest work, the *School for Scandal*. As a dramatic composition the *School* is inferior to the *Rivals*; the plot is involved and its details obscure, the play a series of extraordinarily brilliant scenes, but wanting in cohesion. So powerful is the satire, however, and so real and striking are the characters, that Sheridan's contempt for the dramatic unities has never diminished the enthusiastic approval awarded to it from the first. It brought back prosperity for a time to Drury Lane, where Sheridan's idle and careless management had done much mischief. In 1779 he produced the *Critic*, a play of even more heedless composition than the *School for Scandal*, but teeming from end to end with a sparkling wit which carries it over all obstacles. This was Sheridan's last dramatic effort, with the exception of a tragedy called *Pizarro*—in no respect superior to Mr Puff's tragedy—prepared for the stage by him some twenty years later.

Sheridan now began to turn his thoughts to another field for ambition, and on the dissolution of parliament in 1780 he was elected member for Stafford. He adhered to the opposition, then under the leadership of Burke and Fox, and on the change of government in 1782 became under-secretary for foreign affairs under Rockingham, afterwards serving as secretary to the Treasury in the coalition ministry (1783). His parliamentary reputation, however, may be said to date from the impeachment of Warren Hastings. His part in the attack was to expose the connivance at the plundering of the Begums of Oudh, on which subject he delivered three great speeches. The first, in the House of Commons, was a marvel of oratory, and produced such an effect upon the audience that the House decided to adjourn, as being still too much under the influence of this wonderful speech to give a cool, impartial vote. The second, on the actual trial of Hastings, was rather less successful, and the answer to the pleadings of Hastings' counsel, seven years later, was, comparatively speaking, a failure. The reputation thus acquired was not sustained, his habitual indolence perhaps rendering him incapable of a continued effort. During the thirty-two years he sat in parliament Sheridan took an active part in the debates, and was known as a lively and occasionally impassioned speaker. In 1794 he again electrified the House by a magnificent oration in reply to Lord Mornington's denunciation of the French Revolution, but with this exception he never again rose to the same height. At the critical period of the mutiny at the Nore he did much to strengthen the hands of the government by his unselfish and patriotic support. He remained the devoted friend and adherent of Fox till the latter's death, and was also the defender and occasional mouthpiece of the Prince Regent. Few rewards fell to his share. In 1806 he was appointed Receiver of the Duchy of Cornwall, and in 1806 held for a short time the small post of treasurer to the navy. In 1812 he was defeated at the polls at Westminster, and his parliamentary career came to an end.

To turn to his private life. In 1792 his first wife, to whom he had been passionately attached, though he must at times have caused her great unhappiness, died; and three years later he married again a Miss Ogle, daughter of the Dean of Winchester, who survived him. The affairs of the theatre had gone badly. The old building had to be closed as unfit to hold large audiences, and a new one built which was opened in 1794, but this also was destroyed by fire in 1809. This last calamity put the finishing touch to Sheridan's pecuniary difficulties, which had long been serious. Misfortunes gathered thick upon him, and his latter days were spent in trouble and privation. He died on the 7th July 1816 in great poverty, with bailiffs actually in possession of his house; but the friends of his prosperity came forward to give him a magnificent funeral in Westminster Abbey.

See the Memoirs prefixed to editions of his works by Leigh Hunt (1840), James P. Browne (2 vols. 1873-75), and Stainforth (1874); Lives by Watkins (2 vols. 1817) and Moore (2 vols. 1825); *Sheridan and his Times* (2 vols. 1859); *Memoirs of Mrs Frances Sheridan*, by her granddaughter, Alicia Le Fanu (1824); W. Fraser Rae, *Wilkes, Sheridan, and Fox* (1874); the short life by the present writer ('English Men of Letters' series, 1883); Percy Fitzgerald, *Lives of the Sheridans* (2 vols. 1887); and Lloyd C. Sanders, *Sheridan* ('Great Writers' series, 1891).

Sherif, or SHEREEF, designates a descendant of Mohammed through his daughter Fatima and Ali. The title is inherited both from the paternal and the maternal side; and thus the number of members of this aristocracy is very large among the Moslems. The men have the privilege of wearing green turbans, the women green veils, green being the prophet's colour. Many of these sherifs founded dynasties in Africa; the line which rules in Morocco (q.v.) boasts of that proud designation. The ruling prince of the district of Mecca and guardian of the Kaaba (q.v.) is called sherif, sometimes for the sake of distinction grand sherif.

Sheriff (A.S. *scir-geréfa*, the reeve or fiscal-officer of a shire), in English law, is an officer whose duties are chiefly ministerial (for he has only a few trifling judicial duties). The office is of great antiquity. The sheriff was (next to the ealdorman or earl, and the bishop) the chief man of the shire, and seems to have possessed unlimited jurisdiction to keep the peace; to have presided in the courts of the shire; to have punished all crimes, and have redressed all civil wrongs. The sheriff was formerly chosen by the inhabitants, though probably requiring confirmation by the crown. But popular elections for that purpose were put an end to by a statute of 9 Ed. II., which enacted that in future the sheriffs should be assigned by the chancellor, treasurer, and judges. Ever since that statute the custom has been, and now is, for the judges, the Lord Chancellor, and Chancellor of the Exchequer to meet in the Court of Exchequer (now the King's or Queen's Division) on the morrow of St Martin (12th November), and there propose three persons for each county to the crown. On the morrow of the Purification (3d February) the names are finally determined on, the first on the list being generally chosen; and the sovereign afterwards 'pricks off' the person selected, by piercing the list with a punch opposite his name, and so appoints him to the office. A sheriff continues in office for one year only, and cannot be compelled to serve a second time. The office is not only gratuitous, but compulsory, for if the person appointed refuses he is liable to be fined. In practice, country gentlemen of wealth are appointed. As military head of the county the sheriff was superseded by the Lord-lieutenant (q.v.) as early as the reign of Henry VIII. In the city of London the sheriffs are appointed not by the crown, but by the citizens. The sheriff has important official duties in elections of members of parliament. He is, by his office, the first man in the county, and superior to any nobleman while he holds office. He has the duty of summoning the *posse comitatus*—i.e. all the people of the county—to assist him in the keeping of the peace; and if any person above the age of fifteen, and under the degree of a peer, refuse to attend the sheriff after due warning, he incurs a fine or imprisonment. The chief legal duty which the sheriff discharges is that of executing—i.e. carrying out—all the judgments and orders of the courts of law. It is he who seizes the goods of debtors or their persons, and puts them in prison. For this purpose he has a number of persons called bound-bailiffs (or, in popular dialect, bumbailiffs), who in practice do this invidious work, and give a bond to the sheriff to protect him against any mistake or irregularity on their part. The necessity of this bond is obvious, for the doctrine of law is that the sheriff is personally responsible for every mistake or excess made or committed by the bailiffs in executing the writs or process of the court; actions may be brought against him by indignant prisoners, or debtors whose persons or goods have been arrested; and the courts watch jealously the least infringement of personal rights caused by these bailiffs. Every sheriff ('high-sheriff') has an under-sheriff, usually a solicitor, who takes charge of the legal business; and he is required to name a deputy in London to whom writs may be delivered. See works by Churchill and Bruce (1879) and Atkinson (new ed. by Melsheimer, 1878).

The sheriff's extensive jurisdiction, gradually acquired at the cost of local courts, has been gradually infringed upon, partly by the exercise of the royal prerogative, and partly by parliament. But in England it suffered more from the appointment to the office of men not specially qualified to exercise judicial powers, and from the consequent usurpation of their functions by the supreme courts. The same causes operated in Scotland, though to a less extent. In England they resulted in the almost entire abolition of the judicial functions of the sheriff. In Scotland they resulted in his being deprived of the more important parts of the criminal jurisdiction, particularly of the power to punish by death, and in his civil jurisdiction being limited mainly to questions affecting movables. In both countries the office was entrusted to gentlemen having estates in the county; in some cases it was hereditary; these arrangements tended to a separation of the duties of the office into the honorary and the laborious—the former being performed by the sheriff, and the latter by his deputy. In Scotland this separation was completed by the act of Geo. II., which entirely separated the offices by the transference of the power of appointing the depute from the principal sheriff to the crown. In England this complete separation has never become necessary, from the fact of the sheriff's power having been much more crippled than in Scotland. Indeed, in England, so purely honorary and ministerial has the office become, that it has been held by a female, and in Westmorland the office was hereditary down to 1849. The duty of enforcing the orders of the supreme courts, which now in England is a principal part of the duties of the sheriff, appears to have been engrafted on the office—probably on the theory that these orders were those of the King himself. In Scotland the sheriff has never been called on to enforce any writs except those actually and not merely in name proceeding at the instance of the crown.

SHERIFF, in Scotland, is a title given to the magistrate and judge of a county. In Scotland the office of sheriff is still that of a local judge, and not merely ministerial, as in England; and the jurisdiction, both civil and criminal, is still very extensive. The duties of the office are now performed by two officials, the sheriff—called sheriff-depute since the abolition of the Heritable Jurisdictions (q.v.) to distinguish him from the heritable sheriff-principal—and the sheriff-substitute. The sheriff-depute, except in the case of Edinburgh and Glasgow, does not reside in the county, but holds courts therein at stated periods. The sheriff-depute is disqualified from acting as advocate in any cause originating in his county, though in other respects he is at full liberty to practise. He is appointed by the crown, must be an advocate of three years' standing, and holds his office for life or good behaviour. The sheriff-substitute was at first appointed by the sheriff-depute, but he is now appointed by the crown, requires to be an advocate or solicitor of five years' standing, and holds office *ad vitam aut culpam*. He resides within the county, and presides over the ordinary sittings of the court. The civil jurisdiction of the sheriff extends to all personal actions on contract or obligations without limit, actions for rent, and other questions between landlord and tenant. His powers are limited in matters of heritable right and title to cases where the value does not exceed £1000, or £50 by the year. He can, however, adjudicate on questions of possession beyond these limits, and he can also deal with questions of servitude and nuisance. He cannot decide questions of *status*, but he may entertain questions of aliment. There are various other matters with which the sheriff may deal, such as questions of poor-law, lunacy, elections, &c. Besides his ordinary court the sheriff holds two statutory courts, the Debts Recovery Court and the Small Debt Court. The former is for actions where the value, exclusive of expenses, exceeds £12, but is less than £50. It is confined to certain specific kinds of action, and has statutory forms of procedure. The latter is for actions not exceeding £12 in value, or which have been restricted to that amount. This latter court is made great use of by all classes of the community. The sheriff has also jurisdiction in cases of bankruptcy and insolvency. Against most judgments in ordinary cases by the sheriff-substitute there lies an appeal to the sheriff, and in some cases to the Court of Session. In criminal cases the sheriff has jurisdiction in all the minor offences which do not infer death or banishment, but his powers of punishment are practically limited to imposing a sentence of not more than two years' imprisonment. The forms of trial in use before the sheriff are jury trial and cases which are brought under the Summary Jurisdiction Acts. Changes of considerable importance, and in many of the details of criminal procedure, were introduced by the Criminal Procedure (Scotland) Act, 1887. The sheriff's jurisdiction excludes that of the justices of peace in riots. He has charge also of taking the precognitions in criminal cases, in which he is assisted by the procurator-fiscal. He revises the lists of electors, and returns the writs for the election of members of parliament; and this last is almost the only duty which he performs in common with the English sheriff. An idea of the multifarious duties performed by the Scotch sheriff may be gathered from the statement that he exercises somewhat similar functions to those which in England are exercised by the commissioners in bankruptcy, county-court judges, the stipendiary magistrates, recorders, revising barristers, and coroners. The office of Commissary (q.v.) has been amalgamated with that of sheriff. Additions to the miscellaneous duties of the Scottish sheriffs are not infrequently made in the course of legislation. See COUNTY.

The Sheriff-clerk, in Scotland, is the registrar of the sheriff's court, and as such has charge of the records of the court. He registers, and, when required by the proper party, issues the sheriff's judgments. He also conducts what correspondence may be required. He has important duties to perform in regulating the summary execution which is issued in Scotland against the debtors in bills of exchange, promissory-notes, and bonds, without the necessity of any judicial suit. See J. D. Wilson, *Practice of the Sheriff Courts of Scotland*.

In the United States the office of sheriff is mainly ministerial; the principal duties being to maintain peace and order, to attend courts as administrative officer, to guard prisoners and juries, to serve processes and execute the judgments of the courts, and to preside at inquisitions. In most of the states the sheriff is appointed by the popular vote, and the shrievalty in such places as New York is a highly paid and highly coveted political office. In all the states there are deputy-sheriffs, who are the servants and agents of the sheriff; and in some of the states there is an under-sheriff, who does duty for the sheriff in his absence. See Murfree's *Treatise on the Laws of Sheriffs* (St Louis, 1884).

Sheriffmuir, in Perthshire, on the northern slope of the Ochils, 2½ miles ENE. of Dunblane, was the scene, on 13th November 1715, of an indecisive battle between 8400 Jacobites under the Earl of Mar and 3500 Hanoverians under the Duke of Argyll. The Macdonalds, who formed the centre and right of the Highland army, completely routed the left of their opponents; but Argyll with his dragoons had meantime driven the left of the Highlanders back for two miles. About 500 fell on each side.

Sherlock, WILLIAM, was born in Southwark in 1641, had his education at Eton and Peterhouse, Cambridge, and became Rector of St George's, Botolph Lane, London, in 1669. Later he was preferred to be prebendary of St Paul's, Master of the Temple, Rector of Therfield in Herts, and Dean of St Paul's (1691). At the Revolution he refused at first to take the oath, but soon complied. He died at Hampstead in 1707. He wrote about sixty books or pamphlets, mostly controversial. His *Practical Discourse Concerning Death* (1689) was long famous, and was styled by Addison 'one of the strongest Persuasives to a Religious Life that ever was written in any language.' The *Vindication of the Doctrine of the Trinity and of the Incarnation* (1690) opened up a fierce and unseemly controversy with South (q.v.) and others, which is said to have been closed only by the express desire of the king. Sherlock attempted to explain the relations of the three Persons by 'a mutual self-consciousness,' but his metaphysical powers were not subtle enough for his task, and he cannot be said to be altogether undeserving of South's charge of Tritheism. His *Case of Allegiance to Sovereign Powers Stated* (1691) was published to justify his own swallowing of the oath, and at once excited a raging controversy. Other works discussed Future Judgment (1692) and Future Punishment (1704–5), but these have long lost their importance.

His son, THOMAS SHERLOCK, was born in London in 1678, educated at Eton and Catharine Hall, Cambridge, and in 1704 succeeded his father as Master of the Temple. In 1715 he became Dean of Chichester, in 1728 Bishop of Bangor, in 1734 of Salisbury, and in 1748 of London. He died in 1761. Sherlock was a strenuous Tory, yet so much of an observer of the times as to earn Bentley's nickname of Cardinal Alberoni. His volumes of Temple Sermons were highly praised in their day, and the Rev. T. S. Hughes edited his complete writings, including treatises against Hoadley, on prophecy, the *Trial of the Witnesses* for the resurrection, &c. (5 vols. 1830).

Sherman, capital of Grayson county, Texas, 64 miles by rail N. of Dallas, contains a fine court-house and gaol, has foundries and several planing-mills, &c., and is a depôt for grain and cotton. Pop. (1890) 7338.

Sherman, WILLIAM TECUMSEH, eighteenth general-in-chief of the United States army, was born in Lancaster, Ohio, February 8, 1820, the sixth son of Judge Sherman, who died when William was nine years old. He attended school in Lancaster until 1836, then was appointed to a cadetship at West Point, and graduated in July 1840 sixth in a class of forty-two. He was commissioned second-lieutenant in the Third Artillery and ordered to Florida, where there was some trouble with the Seminole Indians, and was afterwards stationed at Fort Morgan and Fort Moultrie, and from 1846 to 1850 in California. Seeing no prospect of promotion Sherman resigned from the army in 1853, having previously married Miss Ellen Boyle Ewing, daughter of Thomas Ewing, secretary of the Interior, and entered civil life. He was a banker in San Francisco for several years, and at the beginning of the civil war was superintendent of the Louisiana Military Academy at Alexandria, which position he immediately resigned. In May 1861 Sherman was commissioned colonel of the Thirteenth Infantry, and joined his regiment at Washington. In the battle of Bull Run he commanded a brigade, and for good conduct in that engagement was promoted to brigadier-general of volunteers. Sherman was one of the first to estimate properly the serious nature of the struggle before the country. In August he was sent to Kentucky, but when he asked for 200,000 men to put an end to the war in that section, the authorities at Washington looked on his demand as wildly extravagant, if not insane, and deprived him of his command. But soon after he was given a division in the Army of the Tennessee, and in April 1862 displayed both coolness and skill in the severe two days' battle of Shiloh, where he was wounded, but would not leave the field. Grant afterwards wrote: 'To his individual efforts I am indebted for the success of that battle.' In May he was made a major-general of volunteers, and stationed at Memphis.

Copyright 1892 in U S by J. B. Lippincott Company

In the various movements made by General Grant against Vicksburg Sherman was most active, commanding the famous Fifteenth Corps of the Army of the Tennessee, and being next in rank to Grant. Immediately after the surrender of that Confederate stronghold, July 4, 1863 (the date of his brigadiership in the regular army), he moved against General J. E. Johnston at Jackson, Mississippi, and drove him out of that city. In November Sherman joined Grant at Chattanooga, and rendered excellent service in the great victory won there on the 25th, withstanding a long series of attacks intended to crush his command; and a few days later he hurried to relieve Burnside, besieged at Knoxville by General Longstreet, whose forces fled at the approach of the Northern cavalry. On 12th March 1864, the same day that Grant became commander-in-chief, he appointed Sherman to the command of the south-west, with headquarters at Nashville. In April he commenced his campaign against Atlanta, his command consisting of the armies of the Cumberland, Ohio, and Tennessee, in all about 100,000 men, with 254 guns. Moving from Chattanooga Sherman first encountered General Johnston at Dalton, May 14, and, by repeatedly turning his position and constantly pursuing and pressing him, drove him to Cassville and beyond the Etowah, thence to a strong position on Kenesaw Mountain (where the Union army was at first heavily repulsed), and finally to Atlanta, the direct attack on which began on July 17. Many bold sorties were made by General John B. Hood, who had superseded General Johnston, and fierce encounters occurred at Peach Tree Creek, Ezra Church, and elsewhere, all unfavourable to the Confederates, until on 1st September they evacuated the city, and Atlanta was won.

After giving his gallant army a rest Sherman moved out of Atlanta on his famous march to the sea, with about 65,000 men. Passing between Augusta and Macon, and meeting with little serious opposition, for Hood and his army had been disastrously defeated by General Thomas in the battle fought near Nashville, he reached the outworks of Savannah on December 10—a march of 300 miles in twenty-four days, with a loss of 63 killed and 245 wounded. The works were soon carried, and on the 20th General Hardie evacuated the city, Sherman marching in on the 21st. To President Lincoln he wrote: 'I beg to present you as a Christmas gift the city of Savannah, with 150 guns, plenty of ammunition, and 25,000 bales of cotton.' For his great services he had already been made a major-general in the regular army, and now he received the thanks of congress for his 'triumphal march.'

Early in February Sherman and his army left Savannah for the north, and by the 17th, compelling, by another flanking movement, the evacuation of Charleston, he had reached Columbia, the capital of South Carolina. Thence he moved on Goldsboro' by way of Cheraw and Fayetteville, fighting by the way severe battles at Averysboro' and Bentonville in March, and aiming either to cut off Lee's retreat or to join Grant before Richmond. But on April 9 Lee surrendered, and word of this coming to General Johnston, he made terms with Sherman on the 17th, which, however, were disapproved as too lenient by Secretary Stanton and repudiated: Lincoln had been assassinated on the 14th. The surrender of Johnston's army was soon followed by all the other Confederate forces then in the field, and the four years' war was at an end.

Before the disbandment of Sherman's army and the Army of the Potomac, they passed in review at Washington before President Johnston and General Grant on May 23 and 24, 1865. Sherman took leave of his troops in a field order of May 30. For the four years following he was in command of the division of the Mississippi; and when Grant became president Sherman succeeded to the head of the army with the rank of general, having been previously promoted to lieutenant-general. In 1872 he visited Europe, everywhere receiving distinguished honours; and in 1874, at his own request, to make room for Sheridan, he was retired on full pay. His remaining years were spent in St Louis and in New York, where he died February 14, 1891. He received a public funeral in both these cities, and was buried by the side of his wife and favourite son William in the St Louis Cemetery. Many lives have been published of Sherman, but much the most valuable are his own Memoirs, first issued in two vols. in 1875, and of which revised editions were published in 1885 and 1891. A noble equestrian statue of Sherman adorns New York City.

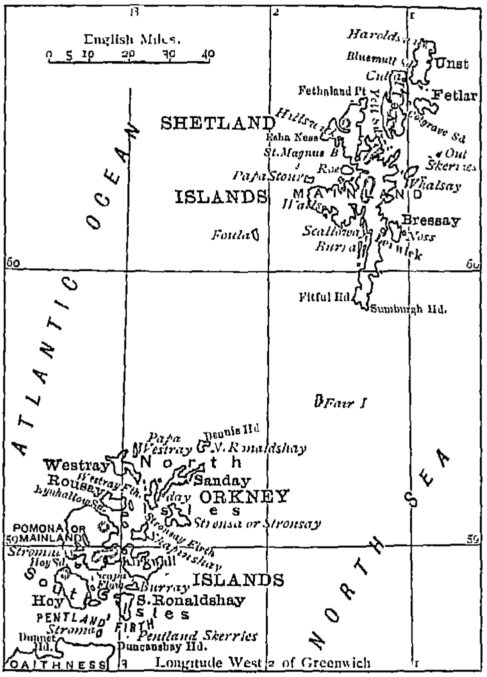
JOHN SHERMAN, senator, a younger brother, was born at Lancaster, 10th May 1823, was for a time attached as rodman to a corps of engineers, and then studied law with his brother Charles, whose partner he became after his admission to the bar in 1844. From 1855 to 1861 he sat in congress, from 1859 as chairman of the committee of ways and means; and in the senate, of which he was a member from 1861 to 1877, he was for many years chairman of the committee on finance. As a congressman he had been eminent for the steady but statesmanlike opposition which he offered to slavery, and on the outbreak of the war he raised a brigade in Ohio largely at his own expense. But he helped the Union cause best by his labours in the senate to strengthen the public credit and provide funds for the support of the armies in the field. Two bills for which he was largely responsible were that for the reconstruction of the seceded states and that providing for the resumption of specie payment on January 1, 1879. A warm supporter of Mr Hayes, he was appointed by him in 1877 Secretary of the Treasury, and before the end of 1878 had prepared such a redemption fund in gold as raised the legal-tender notes to par value, and brought it about that on January 1 there was no demand for their redemption. In 1881 and 1887 he was again returned to the senate, was for a while its president, and afterwards chairman of the committee on foreign relations. In 1880-84-88 he was an unsuccessful though popular candidate for the Republican nomination for the presidency. See Life by Bronson (Columbus, 1880), and his *Selected Speeches on Finance and Taxation* (1879).

Sherry, a name derived from Xeres (q.v.), or Jerez de la Frontera, near Cadiz, and applied to the better kind of white wines grown over a considerable area in the neighbourhood of Xeres, between the mouths of the Guadalquivir and Guadalete. Sherries may be divided into the Amontillado class and the Montilla—the latter the lighter and drier, with grape spirit added only when it is required to enable the wine to stand transport. The Amontillados are generally fortified so that sherry of this type contains about 32 degrees of proof spirit. So-called 'natural sherry' has from 2 to 4 per cent. of spirit added to make it keep. Sherries are coloured by introducing wine boiled down to a liqueur, and sweetened by mixing with them wine made from over-ripe grapes. The trade is largely in the hands of Englishmen settled at Xeres: Cadiz is the chief shipping port. The export is mainly to England, and in 1891 amounted to 2,135,969 gallons—64 per cent. less than in 1873 (the year of largest imports), after which date there was a steady decrease. See SACK, WINE.

Sherwood, MARY MARTHA, a prolific writer of religious and juvenile fiction, was the daughter of Dr Butt, chaplain to George III., and a descendant of Sir William Butts, physician to Henry VIII. She was born at Stanford, Worcestershire, May 6, 1775, and from early years was an indefatigable narrator of stories. In 1803 she married her cousin Henry (afterwards Captain) Sherwood, and sailed for India, where she showed strong sympathy with the religious labours of Henry Martyn and Dr Corrie, Bishop of Madras. Her husband predeceased her (1849), and she died at Twickenham, September 22, 1851. Her first book, the *Traditions*, was written when she was seventeen. Her *Susan Grey* (1802) was one of the first attempts to write on religious subjects for the poor. Of her seventy-seven religious works and stories the least forgotten are the *Little Woodman*, *Little Henry and his Bearer*, and the *Fairchild Family*. A collected edition of her works in 16 vols. was issued in New York. See Life (chiefly autobiographical), by her daughter Sophia Kelly (1854).

Sherwood Forest, a stretch of hilly country in the west of Nottinghamshire, lying between Nottingham and Worksop, and extending about 25 miles from north to south and 6 to 8 miles from east to west. It was formerly a royal forest, and the traditional scene of many of the exploits of the famous Robin Hood (q.v.); but it is now almost wholly disafforested, and is occupied by gentlemen's seats and fine parks. The town of Mansfield and a number of villages are situated within the ancient bounds. Numerous remains of the old forest are still to be seen. See R. White's *Nottinghamshire and Sherwood Forest* (Worksop, 1875).

Shetland, or ZETLAND (Scand. *Hjaltland*, 'high land'), a group of more than a hundred islands, islets, and skerries, forming the northernmost Scottish county, whose capital, Lerwick, is 116 miles NE. of Kirkwall, 300 N. by E. of Edinburgh, and 222 W. of Bergen in Norway (direct distance). Extending 70 miles, and 36 in extreme breadth, they have a total area of 551 sq. m., the largest of the twenty-nine inhabited islands being Mainland (378 sq. m.), Yell (83), Unst (47), Fetlar, Bressay, Whalsay, and Foula. The cliff-scenery is very fine, and the sounds and *voes*, or firths, are so numerous that no spot is more than 3 miles from the sea. The surface is more rugged than that of Orkney, the highest points being Ronas Hill (1475 feet) in Mainland, and the Sneug (1372) in Foula. Metamorphic crystalline rocks predominate, with isolated Old Red Sandstone; and the soil is peaty, barely one-sixth of the total area being in cultivation, whilst trees there are none. The live-stock includes from 70,000 to 100,000 sheep, some 19,000 cattle, and nearly 5000 shaggy 'Shetland ponies,' 9 to 10 hands high. The climate is equable but moist (rainfall, 49 inches); at the longest day the sun sets for only five hours, at the shortest for over eighteen. The herring and other fisheries are the leading industry, having been greatly developed since 1872. Shetland unites with Orkney to return one member to parliament; but it was dissevered therefrom as a county by the Local Government (Scotland) Act, 1889. Pop. (1801) 22,379; (1861) 31,679; (1891) 28,711. Subject, like Orkney (q.v.), to the Scandinavian crown until 1468, Shetland—the *Ultima Thule* of the ancients—is still markedly Norse in many of its characteristics, Norse being still spoken in Foula as late as 1774, and having bequeathed many words to the Shetland dialect. In 1766 it was sold by the



Earl of Morton to the ancestor of the Earls of Zetland, but the present earl's property here is small.

See LERWICK, FOULA, BROCH, CROFTERS, and for the old Udal tenures, ALLODIUM; Scott's *Pirate;* Tudor's *Orkneys and Shetland* (1883); Edmondston's *Shetland Glossary* (1866); and other works by Brand (1701), Sheriff Rampini (1884), and the Rev. J. Russell (1887).

Shiahs. SHIITES.

Shibboleth (properly *Shibbo'leth*, Heb., 'ear of corn,' or 'stream'), the test-word used by the Gileadites under Jephthah after their victory over the Ephraimites, recorded in Judges, xii. 6. The latter could not pronounce the *sh*, and, by saying *s*ibboleth, betrayed themselves, and were slaughtered at the ford. All those Hebrew names in the Old Testament which commence with the *sh* have now, through the inability of the Septuagint to render this sound in Greek, become familiar to us, through the versions that flowed from it, as beginning with the simple *s*—e.g. Simon, Samaria, Solomon, Saul, &c. The word Shibboleth is still used to mean a test of opinions and manners.

Shiel, LOCH, a fresh-water lake in the west of Scotland, on the boundary between Moidart in Inverness-shire and Ardgour in Argyllshire, 18 miles W. of Fort-William. It extends 17½ miles south-westward, is 1 mile broad, is overhung by mountains nearly 3000 feet high, abounds in fish, and communicates with the sea by the river Shiel and salt-water Loch Moidart. Prince Charles Edward was here, a fugitive, in 1746; and Queen Victoria in 1873. At the head is Glenfinnan (q.v.).

Shield, a portion of defensive armour held in the left hand or worn on the left arm to ward off sword-strokes or missiles. The earliest known shields date from the close of the bronze age. They are circular and flat, or but slightly convex, with a central boss, under and across which the handle is fixed. The material is thin beaten bronze, strengthened by a turned-over rim round the circumference, and by the surface being embossed with concentric circles alternating with circular rows of small bosses. The Greek shield of the Homeric period was also of bronze, circular, convex, and often ornamented with devices. The Etruscan shield of bronze, of which there is a fine specimen in the British Museum, is also circular and ornamented in concentric bands of embossed work round the central boss. The Roman infantry used a light round shield about three feet in diameter, and the cavalry carried a smaller buckler also of a round form covered with hide, while the spearmen had a large oblong convex shield of wood and leather strengthened with iron, which covered the whole body. The early Germanic shields were also large, oblong, and convex, and Tacitus, in the 1st century of our era, mentions that they were painted with gay colours and devices. These are supposed to have been the precursors of the heraldic devices on the shields of the middle ages. From the downfall of the Roman empire to the 10th and 11th centuries there seems to have been considerable variety in the forms of the shields in use among European nations, though the circular shield was perhaps the most common. The shields of the Anglo-Saxon invaders of England and of the Scandinavian vikings were mostly circular. But the Norman shield of the 11th century was kite-shaped (see BAYEUX TAPESTRY), and the triangular form continued to prevail till the 15th century, becoming gradually shorter and more obtusely pointed, or heater-shaped. After the 14th century the small round buckler came into fashion, and retained its place till the 16th century. By this time the use of firearms had made the shield practically useless in warfare. The large shields used at tournaments and pageant shields and bucklers were often highly ornamented, some of the latter being among the most beautiful works of art of the middle ages. Round shields or *targets*, covered with hide or leather, ornamented with brass studs and bosses, were used in the Highlands of Scotland down to 1745. Many savage tribes still use shields of wood or hide of various forms. For the heraldic shields, see HERALDRY, Vol. V. p. 660.

Shield, WILLIAM, composer, was born 5th March 1748, at Swalwell in Durham, and was apprenticed to a boat-builder; but he studied music with zeal by help of Avison, and composed anthems that were sung in the cathedral of Durham; and ere long he was a conductor of concerts at Scarborough. He published a comic opera, *The Flitch of Bacon,* in 1778, and, now composer to Covent Garden (1778–97), produced several other dramatic works, including *Rosina* (1783), *The Poor Soldier* (1784), *The Woodman* (1792), *Two Faces under a Hood* (1807). But he is best known by his songs, amongst which are 'The Heaving of the Lead,' 'The Arethusa,' 'The Thorn,' 'The Ploughboy,' and 'The Wolf.' The tune of 'Auld Lang Syne,' as now sung (based apparently on an old Scotch tune), was introduced into his *Rosina;* the authorship both of it and of 'Comin' through the Rye' have even been claimed for Shield. In 1807 he published *An Introduction to Harmony* (2 vols.), in 1817 *Rudiments of Thorough Bass,* and several collections of glees, ballads, trios, &c. In 1792 he travelled and studied in France and Italy. At his death, 25th January 1829, he was Master of the King's Musicians. See a 'Memorial' published in 1891 in connection with the erection of a tombstone in his native parish.

Shields, NORTH, a seaport and market-town of Northumberland, situated on the north bank of the Tyne, near the mouth of that river, 8 miles ENE. of Newcastle-upon-Tyne. In the 13th century the germ of the present town was a collection of huts or sheds temporarily used by the fishermen of the Tyne. These were called 'shieles,' a name which has since been corrupted into 'Shields.' The prior of Tynemouth previous to 1279 built twenty-six houses and a quay here, but the burgesses of Newcastle, who claimed an exclusive right to the trade of the Tyne, frustrated his design to establish a town where, so they contended, 'no town ought to be.' For five hundred years North Shields, oppressed by Newcastle, remained a mere village, but during the 19th century its development has been rapid. The town is without any architectural character, the streets being monotonously plain, and, near the river, narrow and dingy. The principal public buildings and institutions are the town-hall (1844), the theatre-royal, the covered market, the free library and museum, the Tyne Sailors' Home (1856), and the Master Mariners' Asylum (1837–38). North Shields is within the parish of Tynemouth. There are five churches in the town (four Established Church and one Roman Catholic Church) and seventeen chapels. The Northumberland Park (in which are the remains of St Leonard's Hospital) formed part of Spital Dene, and abuts on the Tynemouth Road, covering an area of about 17 acres. The mouth of the Tyne forms an important harbour; the depth of water on the bar at low-water (spring-tides) is 20 feet; at high-water, 37. Within the borough are two extensive docks—the Northumberland (opened 1857) and the Albert Edward (opened 1884), the one having an area of 55 acres, the other of 24. Upwards of 2¼ million tons of coal and coke were shipped from these docks in 1890. The principal imports are corn, timber, and esparto grass. About 101,000 tons of shipping are registered at the port of North Shields. There is much building and repairing of steam and sailing vessels and manufacture of anchors, chain-cables, ropes, &c. At the fish-quay (4½ acres in extent) there were landed in the year ending March 25, 1890, 6530 tons of herrings and 6146 tons of whitefish. At Clifford's Fort is a submarine mining station. In conjunction with Tynemouth (q.v.) and three small townships North Shields forms a municipal and parliamentary borough, named after Tynemouth, and sends one member to parliament. The population of the municipal borough of Tynemouth, of which North Shields forms a part, in 1881 was 44,118; in 1891 it was 46,267. This town is the birthplace of the painters George Balmer (1805-46) and Birket Foster (born 1812), also of William Wouldhave (1751–1821), who shares with Greathead the honour of inventing the lifeboat. Henry Taylor (1737–1823), who originated the system of lightships in such places as Goodwin Sands, was from 1772 to his death associated with North Shields.

Shields, SOUTH, a seaport, municipal and parliamentary borough, and market-town of Durham, situated on the south bank of the Tyne at the mouth of that river, 9 miles ENE. of Newcastle-upon-Tyne. On the Lawe, an eminence overlooking the river, the Romans had an important military station, approached from the south by the Ryknield Way. In Saxon times it was called Caer Urfa, and is said to have been the birthplace of King Oswin. Salt-pans were established here in 1489, and glass-works in 1619. The oldest part of the town extends for about two miles along the river-bank, the streets being narrow and dingy. Ocean Road—a fine broad thoroughfare nearly a mile long—stretches from the market-place to the pier. Several of the modern streets are wide and well-built. South Shields is becoming popular as a watering-place. The coast southward is very fine, the cliffs—magnesian limestone of the Permian system—being hollowed into picturesque caves. The principal public buildings are the town-hall, in the centre of the market-place (1768); the public library, news-room, and museum (1859); the marine school (opened 1869); the theatre-royal (1866); and the Ingham Infirmary (1873). South Shields is in the parish of Jarrow (q.v.). There are twelve churches in the borough (ten belonging to the Established Church and two to the Roman Catholic Church) and twenty-six chapels. At the east side of the town are the North and South Marine Parks, 45 acres in extent, divided by the pier parade. A portion of the site of the Roman station, containing the remains of the Forum, treasury, western gateway, &c., has been enclosed by the corporation and laid out as a recreation ground. The south pier—a gigantic breakwater 5218 feet in length, protecting the harbour from the south-east gales, was begun in 1854, and not quite completed at the end of 1891. Nearly 30,000 tons of shipping are registered at the port of South Shields. The harbour is lined with ship and boat yards, iron, glass, alkali, and rope works, paint and varnish manufactories, &c. Within the borough are the Tyne Docks, the property of the North-Eastern Railway, from which 5,695,829 tons of coal and coke were shipped in 1890. The docks were opened in 1859, and cover an area of 50 acres. There is a large colliery in the town—the St Hilda—which was opened in 1810. In an explosion here in 1839 fifty-nine persons were killed. The first lifeboat was built at South Shields, and was used for the first time on January 30, 1790. A memorial to the inventors Wouldhave and Greathead has been erected on the pier parade. Near it is preserved the old 'Tyne' lifeboat which saved no less than 1024 lives. A life-brigade was established here in 1866. A steam-ferry for passengers and carriages plies day and night between North and South Shields. South Shields was incorporated in 1850. Since 1832 it has returned one member to parliament. Pop. (1851) 28,974; (1881) 56,875; (1891) 78,431.

Shifnal, a town of Shropshire, 17 miles E. by S. of Shrewsbury, with iron manufactures. Pop. 3531.

Shigatze, or DIGARCHI, a town of Tibet, stands on the right bank of the Sanpo or Brahmaputra, 140 miles W. by S. of Lhassa, at an altitude of 12,000 feet. Near by is the great monastery (3500 monks) of the Tashilunpo, the residence of one of the Tibetan incarnations of Buddha. Pop. of Shigatze, 9000.

Shîites (also *Sheeahs*; 'sectaries,' from the Arab. *shîah*, 'a party'), the name given by orthodox Muslims or Sunnites to Ali's followers, who call themselves *al-adeliyyah*, 'the right people.' They were the champions of Ali's right to be Mohammed's successor as being his cousin and son-in-law (see CALIF, ALI); and after Ali's death they took the side of his sons Hassan (Hasan), Hussein (Hosaín), and Mohammed ibn al-Hanafiyyah. The Persians, believers in the divine right and even in the divine nature of kings, took this side. All Shîites allegorise the Koran; but the ultra-Shîites, founded by Abdallâh ibn Sabâ, a converted Jew of Yemen, differed from the moderate Shîites or Zaidites in believing in the transmigration of souls, and in calling Ali and his legitimate successors incarnations of God. By Shîite help the Abbâsides in 750 wrested the califate from the Ommiades. Yet, unsound as the Abbasides were, and decided as Persian ascendency was for 100 years, the Shîites gained little. They were the strength of 'the veiled prophet' (see MOKANNA) in 770–779 and of Bâlek 817–837. Their disaffection was one chief reason for the introduction of Turks into the calif's service (830–840). In 765 the death of Jaafar the Veracious, the sixth Shîite Imâm, developed the Ismaîli sect of the Shîites. Those followed the eldest son Ismael; the majority, following Moosâ the second son, were afterwards named *Twelvers*, the series of their Imâms ending with the twelfth. In Irâk in 887 arose the Karmathian branch of the Ismaîlis. In 909 an Ismaîli proclaimed himself in North Africa as the first Fâtimide calif. The 6th calif of this line, Hâkim, was declared to be God's tenth and final incarnation by Darazî, who founded the sect of the Druses. In 1090 Hassan Sabbâh, an Ismaîli of Khorassân, as the Sheikh of the Mountains instituted the order of Assassins, who generally recognised the Fâtimide califate. Ismaîlis are still found in Persia and Syria. The moderate Shîism that has been the national religion of Persia since the native royal line of Safiides ascended the throne in 1499 is more Koranic than Sunnism. It has Hadîth and Sunna (see SUNNITES), but not those of the orthodox Muslims. It has its own modes of religious washing, and its own postures in prayer. Shîites, habitually ill-used in Arabia, absent themselves much from Mecca, and, unable to bless Abu-bekr and Omar, who are buried in Medina, go still less thither. But they do pilgrimage unhindered to the tombs of Ali and Hussein in the pashalic of Bagdad, and to the tomb of Riza, one of their twelve imâms, in Meshhed, the capital of Khorassan, and to the tombs of Shîite saints. They keep the orthodox feasts and others, among which the Moharram feast, occupying the first ten days of the month Moharram (q.v.), and commemorating the martyrdom of Hussein, is the chief. (For the Shîite cry of *Ya Hasan! Ya Hosain*, see HOBSON-JOBSON.) They detest Âyeshah and the founders of the four orthodox schools, and hold all califs save Ali to have been usurpers. They own no califate nor imâmate; these have been dormant since the death of

Mohammed, their twelfth imâm, in 879, but shall be revived in him when he, the Hidden Imâm, reappears as the Mahdi. Shiism, the ancient protest of Persian patriotism against Arabian ascendency, has spread through Afghanistan into India, but toward the west has made no way. The Shiites, divided and subdivided into sects, number 10 millions, most of whom are Aryans. Toleration and free thought are common in towns and among the more cultivated Persians, especially toward the north. In 1736 Nâdir Shah tried but failed to restore the Shiites to orthodoxy.

Shikarpur, an important trading-town and capital of a district in the north of Sind, stands 18 miles W. of the Indus, on the railway leading to Quetta and Pishin. Before the opening of this railway it was a place of very considerable commercial importance, owing to its situation on one of the principal routes between India and Khorassan—viz. that by the Bolan Pass. It occupies a very low site, the adjacent country being often inundated, but the soil is extremely fertile, and yields heavy crops of grain and fruits. Carpets, coarse cottons, furniture, baskets, &c. are made in the town. Pop. 42,496.—The *district* has an area of 10,001 sq. m. and a pop. of 852,986.

Shikarry. See SHEKARRY.

Shilka. See AMUR.

Shillelagh, the cudgel carried by the conventional Irishman, with which he is supposed to delight to play upon the heads of his friends on occasion. The name is borrowed from the once famous oak-forest of Shillelagh in the south-west corner of County Wicklow, which in Rufus' day furnished 'cobwebless beams' for the roof of Westminster Hall. The railway station of Shillelagh, 16½ miles SW. of Aughrim, is the terminus of a branch-line.

Shilleto, RICHARD, the greatest Greek scholar of his day in England, was born in 1810, educated at Shrewsbury and Trinity College, Cambridge, and took the second place in the classical tripos in 1832. Shortly after graduating he married, and thus made himself ineligible for an ordinary fellowship. For some five and thirty years his best energies were given to 'coaching' or private tuition, and it was only in 1867 that he was elected Fellow of St Peter's College, and so obtained leisure to realise the great ambition of his life. This was an edition of Thucydides, of which he only lived to publish the first book, dying on 24th September 1876. Almost the only other memorial of his scholarship that Shilleto left was an edition of Demosthenes, *De Falsa Legatione*, issued in 1844.

Shilling (A.S. *scylling*), a coin whose name is most probably derived from a root *skil*, 'to divide,' apparently because it was deeply marked with an indented cross, so as to allow of its being easily broken in four. The old Saxon coin of this name was worth about 5d. The shilling in our sense was first coined by Henry VII. in 1504; milled shillings were first coined by Charles II. in 1662. The silver shilling is nominally worth the twentieth part of a pound sterling. But the silver of which shillings are made contains 11 oz. 2 dwt. pure silver to 18 dwt. alloy; and a pound by weight of this compound is coined into 66 shillings; so that each shilling contains 80·727 grains fine silver, and its value as bullion is very much less than its nominal value. The shillings in the old coinages of various north European countries had usually a much smaller value—e.g. the Danish copper *skilling* and the silver *schilling* of Hamburg were each worth less than 1d.

Shiloh, a town of the tribe of Ephraim, the first permanent resting-place of the Tabernacle (q.v.), the home of Eli and Samuel, and long the religious centre of Israel. The site is well ascertained—a ruinous village hidden among the hills 20 miles north of Jerusalem.

Shiloh, one of the most desperate battles of the American civil war, takes its name from a log meeting-house, 2 miles from Pittsburg Landing, which is on the Tennessee River, 8 miles above Savannah. Here, on Sunday 6th April 1862, the Confederates (40,000) under General A. S. Johnston attacked and surprised the Union army (33,000) under General Grant. The battle raged from dawn to sunset, the Federal troops being steadily driven back; but the effort to utterly crush Grant failed, and the next day he won back all the ground he had lost, and the Confederates retreated. On the 6th Johnston was killed while heading the charge of a brigade. The Southerners had 1728 killed, 8012 wounded, and 957 missing; the Northerners, 1754 killed, 8408 wounded, and 2885 missing.

Shimonoseki, a town of Japan, at the south-west extremity of the main island and the western entrance to the Inland Sea, was declared a seaport open to foreign traders in 1890. The batteries and a part of the town itself were destroyed during a bombardment by a combined English, French, Dutch, and American fleet in 1864. Pop. 30,825.

Shin, LOCH. See SUTHERLAND.

Shinar. See BABYLONIA.

Shingking. See MUKDEN.

Shingles (probably derived from Lat. *cingulum*, 'a belt') is the popular name for the variety of *Herpes* (q.v.) which is known as *H. zoster*.

Shingles, flat pieces of wood used in roofing like slates or tiles. Such roofs are much used in newly-settled countries where timber is plentiful. The wood is chosen from among the kinds which split readily and straightly, and is usually some kind of fir. It is cut into blocks, the longitudinal faces of which are of the size intended for the shingles, which are then, in Germany, for instance, regularly split off in thicknesses of about a quarter of an inch, but in America are sawn out, somewhat thicker at one end than the other. In the United States shingles, usually some 6 inches wide by 18 long, are in common use, and their manufacture, especially in the Pacific states, has reached enormous proportions. Shaved—i.e. hand-made—shingles of Washington cedar fetch a somewhat better price than the sawn ones, which cost about $2 per 1000. Shingles are laid with one-third of their length (the thick end) to the weather.

Shintôism. See JAPAN, Vol. VI. p. 287.

Shipbuilding. From crossing a river or lake on a floating log, or on two or more logs fastened together raft-wise, the first steps towards shipbuilding were probably Canoes (q.v.) and Coracles (q.v.). The earliest Egyptian drawings show boats constructed of sawn planks, and having sails as well as numerous oars. So far as can be learned from ancient sculptures, the ships of ancient Greeks and Romans appear to have been open, at least in the middle portion; to have been built with keel, ribs, and planking; and to have been strengthened crosswise by the numerous benches on which the rowers sat. Ships continued, however, to be generally of small draught, for they were beached every winter. The Romans built their vessels of pine, cedar, and other light woods; but their ships of war were of oak at the bows, clamped strongly with iron or brass, and having *rostra* or beaks, for use as rams (see TRIREMES).

Copyright 1892 in U.S by J. B Lippincott Company.

With Rome's decline arose a new era for shipbuilding. The hardy Norsemen had chopping seas and Atlantic swells to fight with; their ships differed much from the stately galleys of the empire. A viking war-ship, unearthed in 1880 from a sepulchral mound at Sandefjord in Norway, and now preserved at Christiania, is clinker-built, 78 feet long, 7 wide amidships, and 5¾ deep, drawing less than 4 feet of water; she had 32 oars and one mast, 40 feet high, which probably carried a single square sail. The introduction of galleys by Alfred, pulled by forty and sixty oars, kept the viking war-ships in check; but these galleys were only fit for shore-service. Canute undertook his final invasion with ships of but moderate size, the average complement of each consisting of eighty men only—less than can be carried by many of the small boats now used as part of the equipment of sea-going ships. The 'large ships' in which Richard Cœur de Lion in 1190 conveyed his forces to the Crusades were of but small dimensions, but depended chiefly for propulsion not on rowers but on sails. The voyage to the Mediterranean—longer than those ordinarily undertaken previously—was of itself the source of enlarged experience to the sailors, and led to the improvement and increase of British shipping. The mediæval galley of the Mediterranean is described at Galley (q.v.). Henry V. during the early part of the 15th century ordered the construction of several large ships, the wonder of their time, one of which is recorded to have been about 165 feet extreme length, 112 feet length of keel, and 46 feet beam. Henry VII., and still more Henry VIII., did much to encourage ship-construction both for war and commerce, the latter building the *Great Harry* (see NAVY, Vol. VII. p. 415). The year 1511 saw the construction in Scotland of the *Great Michael*, 'ane varie monstrous great schip,' 240 feet in length, said to have cost about £20,000 Scots. Columbus made his first voyage to the New World in the *Santa Maria*, of 90 feet keel and 29 feet wide, with two small undecked caravels (see also the articles on the navigators Gama, Gilbert, Frobisher, Drake, Magellan, Dampier, Anson, &c., and those on Geography and Polar Exploration).

At this period in the history of shipbuilding the main principles of wood construction were already clearly established, and subsequent development in size, down at least till the beginning of iron shipbuilding, was mainly characterised by such modifications in individual parts or in structural arrangements as made such development possible. Scarcely any advance in the size of ships was made during the reign of Elizabeth, notwithstanding that this was pre-eminently the period of daring navigation. Much was done by her successor to develop both the royal navy and the mercantile marine. He appointed commissions of inquiry into naval affairs, granted a new charter to the East India Company, and endeavoured to raise the standard of knowledge and practice amongst shipbuilders by granting a charter in 1612 to the Shipwrights' Company, and endowing it with jurisdiction over all shipbuilders in the kingdom. The first president of this body was Phineas Pett, master-shipwright of Woolwich Dockyard. To this eminent shipwright, and to his son Peter and Sir Anthony Deane, naval architecture owed much during the 17th century. This period of progress, however, was followed by a century of almost utter stagnation in respect of the application of science to shipbuilding. Skill and thoroughness in ship-carpentry as a craft were indeed not wanting; but there was nothing like adequate application of scientific principles to the evolution and improvement of naval architecture. The best scientific talent during this period and well on into the 19th century was to be found in other countries than England—France, Spain, Sweden, and Denmark; while the British ships produced—particularly ships of war, but also merchant-ships—were, as regards speed, size, and sea-behaviour, far surpassed by the ships of the countries named. 'System' had become so stereotyped that glaring imperfections—such as the lack of both longitudinal and transverse strength—were permitted and perpetuated. At length came a shipbuilder who had courage to break away from established practice, and introduce improved methods of construction. This was Sir Robert Seppings, who began as an apprentice shipwright in the dockyards, and rose to the position of surveyor of the navy, which he held till 1832. To counteract the effect of 'hogging'—i.e. the dropping of the ends of the ship relatively to the middle—he associated with the transverse 'ribs' or frames (see the section of a wood ship shown by fig. 1) an inner framework of ties or 'riders' arranged diagonally. A more important modification still was the introduction of 'fillings' between the frames up to some distance above the bilges. These fillings, occupying as they did the whole space between the ribs, were of great value, both as safeguards in the event of damage to the outside planking and as affording immense assistance to the resistance offered by the lower parts of the ship to hogging. A third important change was in the mode of attaching the deck-beams to the frames at the sides of the ship. This bold shipwright suggested and ultimately effected the reduction of the long 'beak-heads' and lofty square sterns which had for centuries characterised British war-ships. With Seppings' improvements the way was made thoroughly clear for increase in the size and power of wood ships, and the results were exemplified in those towering three-deckers long the pride and glory of the navy, and in the staunch

and elegant merchantmen known on every sea. At the present day, however, wood shipbuilding in Great Britain has so fallen into desuetude as to have become mainly a matter of historic interest. It is a thing entirely of the past in the royal dockyards, and is of the smallest importance in British mercantile shipyards, though at a few minor ports a little wood shipbuilding is still carried on (see table on page 411). In Canada and the United States, on the other hand, the great bulk of new shipping still consists of wood. Wood is even being employed in the construction of steamships of considerable size, and of sailing-ships of dimensions never before attempted in America.

Note.—The corresponding rigging, &c. on the different masts have the same names, prefaced by the name of the mast; such as *Fore*-topsail-yard, *Main*-topsail-yard, *Mizzen*-topsail-yard, &c. See also SAILS.

While wood has thus largely been supplanted by iron and steel in the construction of ships, no such sweeping change has taken place in the means for their propulsion. Steamships have undoubtedly made a wonderful transformation, but spread of sail and 'unbought wind' are still potent factors in the speeding of ships across the ocean. Indeed within recent years the size of sailing-ships and the extent of their rig have enormously increased. Full-rigged ships formerly had only three masts, but four- and even five-masted vessels have become not uncommon. Fig. 2 shows a three-masted ship, with its rigging, spars, and sails. In all substantial points the rig of each mast is the same; to understand one consequently is to understand all. The illustration of *La France* (fig. 3), a five-master of 3784 tons, built in 1890-91, gives evidence of the increased size of hull and the great spread and intricacy of rigging in the colossal ships of modern times. Another and still larger vessel, the *Marie Rickmers*, built by Messrs Russell & Co. of Port-Glasgow in 1891-92 for Messrs Rickmers & Co. of Bremen, has no less than 56,500 square feet of sail area; 21,300 lineal feet, or over 4 miles, of steel wire in the form of shrouds, stays, &c.; and 31,000 lineal feet, or approaching 6 miles, of running cordage. The combined height of the masts is 960 feet, and the combined length of the spars—yards, booms, and gaffs, by which the spread of sail is suspended—no less than 2000 lineal feet. Not only are the sailing-ships of to-day on the whole much larger and better fitted than those which made for themselves great reputations and earned for their owners large fortunes about the middle of the 19th century, but steam appliances for managing the sails, anchor, &c. at sea, and for dealing with cargo in port, are now no inconsiderable part of their equipment. In ponderously-rigged vessels like *La France* and *Marie Rickmers*, intended for long voyages, the need for such appliances is of course almost imperative. In the case of the latter, steam is also employed as an auxiliary to the sail-power for propulsion. The utter incapacity of sailing-vessels to make progress in a calm is one of their greatest defects—a defect increased tenfold in the case of very large vessels. The use of auxiliary steam-engines is not an innovation, as many of the larger vessels of 1850-60 were so fitted. Proving too expensive an item in the equipment of the comparatively small vessels of those days, the auxiliary engine was generally abandoned. Most of the conditions at that time unfavourable are now, however, entirely changed. The weight of engine and coal to be carried for a given power developed and length of voyage undertaken has been marvellously diminished, as also the space occupied. There is now, perhaps, some danger of owners and builders overdoing matters by saddling large sailing-vessels with more powerful engines, and consequently more dead-weight, than the needs of the case warrant. The provision of power sufficient to propel a vessel out of calms at the rate of 5 or 6 knots, or in stormy weather to take her from dangerous proximity to a lee shore, is all that should be aimed at. The *Marie Rickmers* is fitted with triple-expansion engines of about 600 indicated horse-power (i.h.p.), capable, it is estimated, of propelling her, fully loaded and in calm weather, about 7 knots. They are situated near the stern, and they drive a feathering screw-propeller of the 'Bevis' type, the advantages and efficiency of which have already been fully demonstrated in government vessels and large first-class auxiliary yachts. By suitable gearing worked from the engine-room, and led through the hollow of the shafting, the disposition of the blades can be altered relatively to the longitudinal axis of the shafting as may be desired, and even turned so as to be exactly in line with the axis, in which position of course they will offer the least resistance to the vessel's progress while proceeding under sail alone.

Steamships.—When the steam-engine came into vogue as a moving power its utility for the purposes of ship-propulsion occurred to many minds. The Spaniards claim that Blasco de Gary as early as 1543 attempted to propel a vessel by steam in the harbour of Barcelona. Denis Papin (q.v., 1647-1712) on 27th September 1707 employed a steam-engine to drive a model boat, fitted with paddle-wheels, on the river Fulda from Cassel to Münden. Jonathan Hulls in England patented in 1736 and described in 1737 a form of paddle-steamer resembling in many essential features vessels still in use. Other inventors proposed more or less feasible schemes for applying the imperfect forms of the steam-engine as then known to ship-propulsion.

The real beginnings of practical steam-navigation, however, are to be found in the period 1780-90, and almost simultaneously, and probably with little knowledge of what was being done elsewhere, the pioneers of progress set to work in England, France, and America. The Marquis de Jouffroy (q.v., 1751-1832) produced a paddle-steamboat at Lyons, which, on being tried for speed there on July 15, 1783, attained most encouraging success; but, ruined by the Revolution, he failed to bring his invention into practical use. About 1785 two American inventors—James Rumsey (*c.* 1743-92) and John Fitch (q.v., 1743-98)—were independently engaged in steamship experiments. Rumsey in 1786 succeeded in driving a boat at the rate of 4 miles an hour by jet-propulsion—i.e. forcing by steam-pumps a jet of water through the stern. Rumsey died in London just prior to trials being made on the Thames with another boat from his plans. Fitch began his experiments with paddle-wheels in 1785, but more successfully in 1787-88 with a series of paddles worked with a motion resembling that of the Indian's paddle in canoe-propulsion. In April 1790 another of Fitch's boats made 7 miles an hour, and afterwards plied as a passenger-boat on the Delaware. Fitch disputed with Rumsey and others the right to be considered the inventor of steam-navigation; but losing all hope of making headway in America, he went to France in 1793. Again in 1796 he was back in America experimenting with a little *screw* steamboat on a pond in New York. This led to no practical result, and Fitch, disappointed and broken down, retired to Kentucky, where he seems to have committed suicide. For a number of years prior to 1788 experiments with boats driven by paddle-wheels, worked by manual power, had been made by Patrick Miller (1731-1815), a retired Edinburgh banker, in a lake on his estate of Dalswinton, Dumfriesshire. Partly on the suggestion of James Taylor, tutor to his sons, Miller was induced to think of applying steam as the motive power, and to associate with him in his experiments to this end William Symington, a mechanic at the Wanlockhead mines, whose ingenuity had already been publicly attested as the inventor of an engine for road-locomotion. During the summer and autumn of 1788 the skill and ingenuity of Symington were exercised in constructing an engine after the pattern of his own road-engine, on board a boat 25 feet long by 7 feet broad, having twin-hulls with paddle-wheels between. On October 14, 1788, this small craft was propelled through the waters of the lake at the rate of 5 miles per hour, in presence of Robert Burns, Lord Brougham (then a boy), Nasmyth the painter, and other friends of Mr Miller. A year later (October 1789) a larger and more powerful vessel was built and engined for Miller at Carron Ironworks, and tried on the Forth and Clyde Canal, the speed then attained being about 7 miles per hour. Miller, as Carlyle tells us, 'spent his life and his estate in that adventure, and died quasi-bankrupt and broken-hearted.' Symington's pecuniary circumstances did not admit of his experimenting further on his own account, and it was not until twelve years after that he had the opportunity of following up previous efforts with one still more emphatically successful. Meantime in America others were at work besides Fitch, amongst whom were Samuel Morley, Nathan Read, John Steven, Nicholas Roosevelt, Chancellor Livingston, and Robert Fulton. None of these, however, had materially advanced the cause of ship-propulsion by steam, when in 1801-2 Symington completed for Thomas, Lord Dundas of Kerse, a steam-vessel intended for towing purposes on the Forth and Clyde Canal. This was the *Charlotte Dundas*, the 'first practically successful steamboat ever built.' The engine was of Watt's double-acting type, turning a crank on the shaft of the paddle-wheel, which was situated at the stern. Early in 1802 she was launched on the canal at Grangemouth, and in March of the same year she towed two laden barges, each of 70 tons burden, a distance of about 20 miles against a strong headwind in six hours. After repeated trials the proprietors of the canal were urged to adopt the new plan of towing, but, fearing injury to the banks of the canal from the wash caused by the paddles, they declined the proposal. The *Charlotte Dundas* was beached upon the canal bank, and gradually broken up; and Symington, thoroughly disheartened, turned his attention to other matters.

Amongst those who are said, on sufficiently credible authority, to have inspected the *Charlotte Dundas* were Robert Fulton (q.v., 1765-1815) and Henry Bell (q.v., 1767-1830), two enterprising spirits, afterwards destined—the one in America, the other in Scotland—to achieve permanent success with steamships. Fulton went to Paris in 1797, and for some years was engaged experimenting with submarine torpedoes and torpedo boats. About 1801-2, jointly with Chancellor Livingston, then ambassador at the court of France, he built a steamboat on the Seine, the engine for which, proving too heavy for the hull, caused it to collapse and sink. Nothing daunted, Fulton recovered the machinery and placed it in a new and stronger boat, 66 feet long by 8 feet broad. On August 9, 1803, this boat was tried on the Seine, but attained only very limited speed. Fulton, returning to England in May 1804, remained for over two years; and there he ordered and saw completed by Boulton and Watt a steam-engine which Livingston and he intended should be utilised in America. He sailed in October 1806, the engine following, and in August 1807 it was part and parcel of the *Clermont*, a vessel 133 feet long, 18 feet broad, and 9 feet deep, built to Fulton's order. Her first trip between New York and Albany, a distance of 142 miles, was made in thirty-two hours' steaming time, and the return journey occupied thirty hours. The

Clermont was undoubtedly the first steamboat profitably employed—at least continuously—in useful service, and Fulton is accordingly entitled to the distinction of having been 'the first to make steam-navigation an everyday commercial success.' (For the history of American shipbuilding, see p. 410.)

America, with its enterprise and its great natural field for inland-navigation, was infinitely better prepared for the innovation than the old country, with its traditional achievements, conservatism, and prejudices. Yet Henry Bell's venture in 1811–12 is, for various reasons, worthy of note and admiration. Henry Bell, by training a millwright, was proprietor of a hotel at Helensburgh on the Clyde. He had long had convictions as to the high place which the steam-engine would take in ocean-navigation, and had knocked at the door of both the British and American governments for encouragement to prosecute his ideas. The ultimate result of his own *financially unaided* efforts was the renowned *Comet*, which was launched from the yard of John Wood of Port-Glasgow in January 1812. She was 42 feet long, 11 feet broad, 5½ feet draught of water, and her engine, fitted by John Robertson of Glasgow, was of 3 horse-power. She plied on the Clyde from Glasgow to Helensburgh, and thence across the river to Greenock, her speed being about 5 miles per hour. After a time, when her immediate successor, the *Elisabeth*, and other steamers had been built and were running successfully, the *Comet* was lengthened to 60 feet, and fitted with a new engine and a single pair of paddles (at first there were two paddles a side), and attained a speed of 6 miles an hour.

The building of steamships was soon fairly established, and the Clyde took the lead in their construction. While most of them were intended for home river or coasting trade, not a few were built for service at distant ports. Of the four steamers produced in 1814, one, the *Marjory*, was the first steamer to ply upon the Thames, having been bought by a company of London merchants soon after her launch from the yard of William Denny of Dumbarton. She passed through the Forth and Clyde Canal from Bowling to Grangemouth, and reached the Thames six days after leaving the Forth. Soon after the industry received a forward impetus from the energetic genius of David Napier, already a well-known marine engineer, of Glasgow. He thoroughly grasped the possibilities of steam-navigation in connection with coasting and over-sea traffic. In 1818 he established regular steam-service between Glasgow and Belfast with the *Rob Roy*, built by William Denny, and fitted with engines of his own make. In 1819 he established the first line of steamers between Glasgow and Liverpool, and during the subsequent twenty years he engined most of the notable steamers produced by Clyde builders. Meantime, largely owing to the success of the *Rob Roy*, steamers had begun to be built and employed in service at other ports. On the Thames steamers began to ply between London and Margate in 1815–16; and in 1817 James Watt, whose double-acting side-lever type of engine (see STEAM-ENGINE) had played such an essential part in the movement, crossed over to the Scheldt in a steamer named the *Caledonia*, afterwards ascending the Rhine to Coblentz.

Ocean voyages by steamers were at first performed by vessels in which sail almost as much as steam was the power relied on. In this way the Atlantic was crossed in 1819 by the *Savannah*, a vessel 100 feet long and of about 300 tons burden, the passage from Savannah to Liverpool occupying twenty-five days. In 1824 the steam-yacht *Falcon*, of about 175 tons, proceeded from England to India, for the most part relying on sails. In 1825 the *Enterprise*, 122 feet length of keel by 27 feet beam, and of about 470 tons burden, made a passage from London to Calcutta in 113 days, ten of which were occupied by stoppages. The successful inauguration of transatlantic steaming is due to the *Great Western*, built for the Great Western Steamship Company by I. K. Brunel, whose bold genius controlled the affairs of the company, and gave to the maritime world several of its most notable steamships. She was 212 feet long, 35 feet 4 inches beam, 23 feet 2 inches depth of hold, and registered 1340 tons. Her engines, on the side-lever principle, were made by Messrs Maudslay, Sons, and Field of London, and were of 440 horse-power. On Sunday, April 8, 1838, the *Great Western* started from Bristol on her voyage across the Atlantic, her completion and despatch being hastened on account of the fact that, four days before, a vessel named the *Sirius* (taken from the service between London and Cork) had been despatched on the same voyage. The *Sirius* was smaller and less powerful than the *Great Western*, and both vessels arrived at New York on the same day, Monday, April 23—the *Sirius* in the morning and the *Great Western* in the afternoon—the passage thus taking eighteen days and fourteen days respectively. Their arrival was hailed with immense acclamation by a vast concourse of spectators; the event represented a triumph in steam-navigation, regarding the possibility of which much popular unbelief and some scientific doubt had been expressed, and virtually reduced the distance between the Old World and the New by about one-half.

A historical survey of the transatlantic service affords in itself a more complete and connected epitome of steamship development in all its essential aspects than any other single service that can be instanced. The reader may at the outset be referred to the profiles of typical Atlantic steamers from the *Sirius* onwards (fig. 4), reproduced here through the courtesy of the proprietors of *Engineering*. The return passages of the *Great Western* and *Sirius* were even more successful than their outward, both as regards time occupied and fuel consumed, but the undertaking commercially was far from satisfactory. Other pioneer steamers followed, but, with the exception of the *Great Western*, which was kept running at a loss, they were gradually withdrawn from service. Yet in 1839 Mr Samuel Cunard (q.v.) came over to England from Halifax, determined to establish on a secure and satisfactory basis a line of transatlantic steamships. He was brought into contact with Mr George Burns of Glasgow and Mr David M'Iver of Liverpool, the necessary capital was soon raised, and the celebrated 'Cunard' Company, backed by a handsome government subsidy for prospective mail services, was the result. Their first vessels were the paddle-steamers *Britannia*, *Acadia*, *Columbia*, and *Caledonia*, all of about the same dimensions—viz. 207 feet long, 35 feet 4 inches broad, 22½ feet deep, 1154 tons burden, and 740 h.p. Their engines were of the side-lever type, by Robert Napier of Glasgow, return-flue boilers and jet-condensers being used. The *Britannia* inaugurated the mail service by sailing from Liverpool on Friday 4th July 1840, and arriving safely at Halifax after a voyage of twelve days, ten hours. Her return passage was made in ten days; and the mail service thus instituted was thenceforth carried on by these four vessels with great regularity. The average speed then attained was about 8½ knots, and in 1848, when longer and more powerful vessels were running, the average speed had been increased to 10¼ knots.

Iron Ships.—The substitution of iron for wood in the construction of ships' hulls originated in barges and light craft built for canal and inland lake service, and amongst the first builders of iron boats were John Wilkinson, an iron founder at Cartmel in North Lancashire, in 1787 or earlier; Thomas Wilson, on the Monkland Canal, Scotland, in 1818; and John Laird, founder of the Birkenhead firm in 1829. The first iron steamer was the *Aaron Manby*, built at Horsely Ironworks, Tipton, in 1820–21, and named after her designer and builder. The first iron steamer constructed on the Clyde was the *Aglaia*, built in 1832; the first on the Tyne was the *Prince Albert*, built also in 1832. The distrust and opposition which this great change met with not only from the public, but from shipowners, builders, and naval authorities, hindered its development for many years. The building of the *Great Britain* for the Atlantic service during the years 1838–44 was, therefore, a characteristically bold step on the part of Brunel and the company for whom he acted. This remarkable vessel, the marvel of her day, was in herself a striking exemplification not only of the natural evolution of the steamship as regards dimensions, but of the revolution in construction and propulsion under consideration. She was over 320 feet in length, 51 feet beam, 32½ feet deep, her hull was constructed of iron, and she was fitted with a screw-propeller. The employment of the screw in place of paddles was resolved upon in 1839 after the engines designed for paddle-wheels had been partially made, the determination having been come to after painstaking study of the screw as already applied to smaller vessels.

(From *Engineering*, December 1, 1891.)

Screw-propellers.—The idea of employing the principle of the screw for ship-propulsion is known to have been entertained from a period at least as early as the application of steam as the motive power. Claimants for priority in this matter have been most numerous, and the subject is so beset with many intricate and conflicting contentions that it would be futile to attempt a satisfactory statement here. Amongst the first, however, to score decisive success and convince the engineering profession of the practicability of screw-propulsion were John Ericsson (*q.v.*, 1803–89) and Sir Francis Pettit Smith (1808–74). The former with the *Francis B. Ogden* on the Thames in 1836 obtained encouraging success, and the latter with the *Archimedes*, a vessel of much larger size, in 1839 clearly demonstrated the practicability and value of screw-propulsion. The innovation in the case of the *Great Britain* was equally a success; but the great misfortune which overtook her on her fourth voyage from Liverpool to New York in stranding in Dundrum Bay, Ireland, through a misreckoning, interrupted her successful career as a steamship, although she was long afterwards employed in the Australian service. This misfortune, however, helped incalculably to further shipbuilding in iron. The vessel, after lying aground in an awkward situation for about eleven months, was successfully floated, and was found to have sustained comparatively little damage. Many of the shipbuilders and owners who had been hesitating about the judiciousness of employing iron paid visits to the stranded vessel, inspected her after docking, and felt entirely convinced of the suitability of iron for ship-construction. Ocean-navigation by iron steamers was now placed on a thoroughly practical basis, and, although the transatlantic service continued to be conducted by wooden vessels propelled by paddle-wheels for some time longer, the superior efficiency of the screw for over-sea propulsion became more and more understood and accepted.

The advantages of the screw-propeller for ocean-steaming as compared with the cumbrous paddle-wheel are mainly as follows: As an instrument of propulsion purely, and as compared by performances in smooth water, its efficiency is not much greater than the paddle-wheel, but in virtue of its *position* relatively to the body propelled, and to the water through which that body passes, it is vastly more efficient than the paddle for sea-going purposes. Placed at the stern of the vessel, and fully immersed, it acts upon relatively a much larger quantity of water in a given time than the paddle. The rolling motions which so grievously affect the paddle leave the screw almost uninfluenced. If the screw be well immersed to start with, even the pitching oscillation—i.e. the rising of the stern and dipping of the stem—does not entail any great loss of efficiency in large vessels. Again, considerable variations in a ship's draught of water may take place and yet leave the screw moderately efficient; whereas in the case of the paddle a small decrease or increase in the amount of 'dip' of the floats, whether caused by draught of water or by wave-hollows, makes a very material difference.

The virtual monopoly of the Atlantic steamship service which had existed for ten years in the hands of the Cunard Company was first seriously assailed by opposition in 1850. In that year the celebrated 'Collins' Line of paddle-steamships, four in number, American built, of superior power and speed, and backed by a substantial subsidy from the United States government, was established, and the competing Inman Line also sprang into existence. The ultimate issues were greatly in favour of the Cunard Line, the Collins opposition ceasing in 1858 after the loss of two of the vessels and the refusal of the American government of further financial aid. Misfortune and mismanagement were chiefly the causes of this failure, but probably it was also partly determined by the evident and inevitable success of screw-propulsion and iron hulls. It was with iron ships propelled by screws that the Inman Company entered on Atlantic competition. Their first vessel was the *City of Glasgow*, built by Messrs Tod & M'Gregor on the Clyde, their second being the *City of Manchester* by the same builders. Committed to a certain line of development, the Cunard Company in 1852 sent forth the *Arabia*, a wooden paddle-steamer of 2480 tons and 938 h.p. This was followed in 1855 by the *Persia*, the first iron vessel the company owned, and with which they still maintained first place as regards speed. The next addition to the fleet—referred to at the time as the 'champion and model of a mercantile ocean steamship'—was the *Scotia*, built of iron, but still with paddle-wheels as the propulsive agent. She measured 366 feet long, 47½ feet beam, 30½ feet deep, her gross tonnage being 3870. Her engines, by Napier, were 475 h.p. nominal, but she indicated at sea as much as 4200 h.p. Notwithstanding that her early performances surpassed those of any previous vessel, she was destined to be the last of the paddle-steamers built for the Atlantic by the Cunard Company. In the same year which gave her birth the government sanctioned the use of the screw-propeller in the mail-steamers of the company, and the screw-steamer *China* was at once the result. This vessel was followed during the next two years by four others, the result of whose performances finally established the fact that the screw-steamer in point of efficiency and economy, especially with the improvements which had concurrently taken place in the marine-engine, far surpassed the paddle-steamer for deep-sea traffic.

Since the triumph of metallic construction and screw-propulsion was thus assured, no further very radical change has taken place in steamships, but the agents supplying motive power have undergone many important modifications (see STEAM-ENGINE). Development in size and power proceeded more swiftly than ever, and steam-navigation grew and flourished amazingly. Additional companies were formed, and new steamships produced with rapidity not only for the Atlantic traffic, but for services having the widest ramifications. The year 1858 witnessed the completion of the *Great Eastern* (q.v.)—Brunel's and Scott Russell's stupendous creation—and also saw the modest beginning of the now great fleet of the North German Lloyd; and 1861 saw the start of the French Compagnie Transatlantique. The first mercantile steamship company to develop the trade of England with her Indian possessions by way of the Isthmus of Suez was the Peninsular Company, afterwards developed into the more renowned Peninsular and Oriental Company, their first services dating from 1837. The Pacific Steam-navigation Company was established in 1847, and it was in vessels built for it in 1856, engined by John Elder, that the compound principle, destined to prepare the way for the marvellous improvement which has since been gradually effected in the marine steam-engine, received its first satisfactory credentials. The subsequent general adoption of the surface-condenser and the circular multitubular boiler enabled higher pressures of steam to be safely carried and economically produced and used. The employment of steamers on the longest of voyages and at high rates of speed was fairly established about 1877; the Orient Steam-navigation Company then instituted a fortnightly service to Australia, and in 1879 added the *Orient*, and in 1882 the *Austral*, to their fleet, both from the stocks of the Fairfield Company, Glasgow. The *Orient* on trial attained 17 knots, and afterwards made the passage from Plymouth to Adelaide *viâ* Suez Canal in 35 days 16 hours, and the same voyage *viâ* the Cape in 34 days 1 hour, steaming time. It was in a steamer specially built for the Australian service in 1881 by Messrs Napier & Sons—the *Aberdeen*, for Messrs G. Thomson & Co., Aberdeen and London—that the merits of the triple-expansion type of engine, now so universally approved, were first decisively shown, the machinery of this vessel being from the designs of Mr A. C. Kirk, of Messrs Napier. The engines of the *Aberdeen* work with steam having a boiler pressure of 125 lb. per square inch, and expansion takes place in three cylinders. On her first voyage from Plymouth to Melbourne, which occupied 42 days, her average i.h.p. was about 1800 and consumpt of fuel less than 34 tons per day, or at the rate of 1·69 lb. per i.h.p. per hour. In 1883 the New Zealand Shipping Company instituted direct steamship service to New Zealand, and steamers of their fleet, together with those of another company, are now making regular passages averaging from 37 to 40 days. In vessels employed in this service a further extension of the principle of higher pressures and increased measure of expansion—quadruple—has been carried out, with corresponding economic results.

With the year 1874, which saw the production of the *Britannic* and *Germanic*, of the White Star fleet, by Messrs Harland and Wolff, Belfast—each a considerable advance on anything then existing—began what has since proved a practically unbroken and hotly sustained contest for the leading place in the race across the Atlantic. Steamship after steamship has proved more or less an advance on its predecessor in respect of length of keel, splendour of appointment, stupendousness of propulsive power, and consequent shortening of the passage time. Events have been marvellously crowded into a comparatively short period, but, perfection having been so nearly approached, advancement in each case is now less conspicuous than formerly for outstanding improvements in either the shape of the hull or the essential character of the propulsive agents. Each increase in the speed of the present-day high-speed Atlantic steamer represents the resultant of innumerable modifications—some minor, others radical—which engineering experience and skill and the constant improvement in contributory branches of art and manufacture suggest and render possible. For these reasons, and in view of the table on page 406 of speed, dimensions, &c, of Atlantic steamers from the *Britannic* onwards, the references to individual competitors in the race will only be of the nature of a catalogue. For a time the White Star liners maintained first place in the matter of speed, being exceeded, however, as respects dimensions and tonnage by the *City of Berlin* of the Inman Line, produced in the same year, and for a time the longest vessel afloat next to the *Great Eastern*. Roundly stated, the *Britannic* reduced the passage to and from Queenstown and New York to 8¼ days. In 1879 two fresh competitors were in the field, the *Arizona* of the Guion Line, built by the Fairfield Company, and the *Gallia* of the Cunard Company, built by J. and G. Thomson, Clydebank. During 1880–81 the Cunard Company added the *Servia* to their fleet, from the stocks of Messrs J. and G. Thomson; the Inman Company added the *City of Rome* (subsequently transferred to the Anchor Line fleet), from the stocks of the Barrow Company; and the Guion Company the *Alaska*, from the Fairfield yard. After them came the *Oregon* (Fairfield), for the Guion Line, in 1883; the *Aurania* (Clydebank), for the Cunard Company, in the same year; the *America* (Clydebank), for the National Line, in 1884; and the *Umbria* (Fairfield) and *Etruria* (Fairfield), for the Cunard Company, in 1885. The average time between Sandy Hook and Queenstown during 1886 was about 6 days 15 hours as compared with 11 days 19 hours in 1856. A table of speeds and dimensions of representative Atlantic steamers is appended.

Name	*Dimensions* Length, Breadth, Depth	Gross Tonnage	Ind Horse-power	Trial Speed.	Quickest Passage (Eastward)
	Feet			Knots.	D H M
Britannic. ...	455 × 46 × 34	5,004	5,500	16	7 10 53

Furst Bismarck	502½ × 57½ × 38	8,000	16,412	20·7	6 12 58

Twin-screw Steamers.—In 1888–89 four still larger, more powerful, and in many respects more notable steamships were in the field. These were the *City of New York*, *City of Paris*, *Majestic*, and *Teutonic*, the inaugurators of the present twin-screw epoch in the history of the Atlantic navigation; an epoch which has been signalised by the introduction into the same service of magnificent twin-vessels built and owned by German and French firms—e.g. the *Normannia*, *Augusta Victoria*, and *Fürst Bismarck* of the Hamburg American Line, *La Touraine* of the Compagnie Transatlantique—and especially by the construction by the Cunard Company of two new twin-screw vessels of unprecedented power at Fairfield, built to cope with the traffic created by the great Chicago Exhibition of 1893. Their speed was to range from 22 to 22½ knots—i.e. in the latter case to secure a passage across the Atlantic of 5 days 4 hours.

Twin-screws have been employed in steamers for particular services for many years; notably in those for coasting and cross-channel work, where depth of water is restricted, and in vessels of the navy, where manœuvring facility was and is a desideratum. The comparative efficiency of single-screw and twin-screw steamers is still the subject of debate by naval architects, but the conditions under which the evolution of the Atlantic 'express' steamship must proceed make it imperative that twin-screws should form the agents of propulsion. In vessels having engines which develop i.h.p. ranging from as much as 13,000 to 20,000 it has been recognised as inadvisable, even though practicable, to transmit the total power through one line of shafting. The risks run through mishaps to the shafting or propellers of single-screw steamers receive only too frequent illustration, and the concurrent decrease in sail-power obtaining in the larger steamships makes the consequences of such disablement greatly more serious. With twin-screws, each driven by a separate and self-contained set of engines and shafting, ships can, in the event of a break-down to one set of machinery, still pursue their voyage by means of the other set, although somewhat crippled in speed. In the event also of accident to the rudder or steering apparatus the twin-screw vessel can be manœuvred and steered by alternately working the two sets of engines. The duplication of the propelling machinery enables the compartment of the ship containing them to be divided along the centre by a water-tight bulkhead, thus increasing subdivision and enhancing safety in the event of collision or grounding.

Water-tight Subdivision.—Subdivision of the hull by strong water-tight Bulkheads (q.v.) has undoubtedly become the essential factor in the safeguarding of steamships against foundering through collision or grounding on rocks. In the event of the shell being penetrated and an inrush of water taking place, the inflow is confined to the space between two bulkheads, and there is reserve of buoyancy enough in the remaining compartments to keep the vessel afloat. Many of the high-class mail and passenger ships on the Atlantic and elsewhere are so minutely subdivided that even in the contingency of any two compartments being laid open to the sea—as in the case of the shell being penetrated precisely in the line of a dividing bulkhead—the vessel would not sink. In the case of purely cargo-carrying vessels the commercial and other conditions imposed are such as restrict the degree and nature of subdivision, but even in vessels of this class the system is being more and more developed. These very conditions, curiously enough, encourage, nay demand, the extended application of the principle of subdivision in another part of the hull structure of cargo-carrying vessels, sailing as well as steam—viz. throughout the bottom. The carrying of water-ballast (see BALLAST) has for very many years been imposed on vessels compelled by the exigencies of service to proceed light or partially loaded, and this same need, associating itself with the structural requirements arising from the growth in ship's dimensions, has resulted in the general adoption of water-ballast bottoms on the subdivisional or 'cellular' principle. This modification in the internal features of a ship's structure dates from before the time of the *Great Eastern*, in which, as well as in previous smaller ships built by Scott Russell, the cellular system received thorough illustration, although not associated with water-ballast. That it contributes immensely to the security of a vessel in the event of its grounding on rocks or other sunken obstacles is of course easy to understand. Not only is the length of the ship subdivided by transverse bulkheads as already explained, but the top of the cellular bottom or 'inner shell' is in all vital respects as water-tight, though necessarily not so thick, as the outer skin of the ship. We are enabled through the courtesy of Messrs William Denny and Bros., shipbuilders, Dumbarton—a firm who have done more than any other to popularise and improve the cellular system—to reproduce a midship section of the South African mail steamship *Scot* (fig. 5), in which the necessary longitudinal strength in the way of girders and inner plating is happily associated with the transverse deep-floor principle, and the whole utilised for the accommodation and manipulation of water-ballast.

Mild Steel, first used as the building material in France, attracted the attention of the British naval authorities, and about 1875-76 they ordered from home manufacturers the steel requisite for the construction of the cruisers *Iris* and *Mercury*. In 1879 the Allan Line entrusted to Messrs William Denny Brothers the building of the *Buenos Ayrean*, the largest vessel of the Allan Line fleet up to that time, the hull of which was of steel bound with steel rivets. Almost from the first, mild steel found favour with the shipyard workers as being a material capable of much easier manipulation than iron, but its high cost and the exacting test conditions imposed by Lloyd's Registry restricted its use for some years. Improvements in manufacture and enlarged facilities for production, however, gradually cheapened its cost, and enabled Lloyd's to relax their surveillance. Among the advantages of the new material are its great lightness—strength for strength—compared with iron, and its effecting economy in labour and material through lending itself more than iron to being worked while in the cold state; to being readily and safely flanged along the edges, thus dispensing with angle-bars; and to being supplied in plates of greatly increased size. As regards weight-saving, while the change from wood to iron effected a saving of from 30 to 40 per cent. on the weight of ships' hulls, the employment of steel effected a further economy in weight of almost 15 per cent. Roughly, therefore, the steel ship of to-day is 50 per cent. lighter than a wooden ship of former times of similar dimensions and tonnage. Finally the greater safety of steel ships, or the diminished risk of heavy damage requiring repair, in the event of their getting aground, has commended steel to shipowners and marine insurance societies. Through the superior malleability and ductility of the material, steel ships have again and again come comparatively scathless out of ordeals which would have proved fatal to ships built of iron. At the present time quite 90 per cent. of the shipping produced in Britain consists of steel-built vessels (see table, page 411).

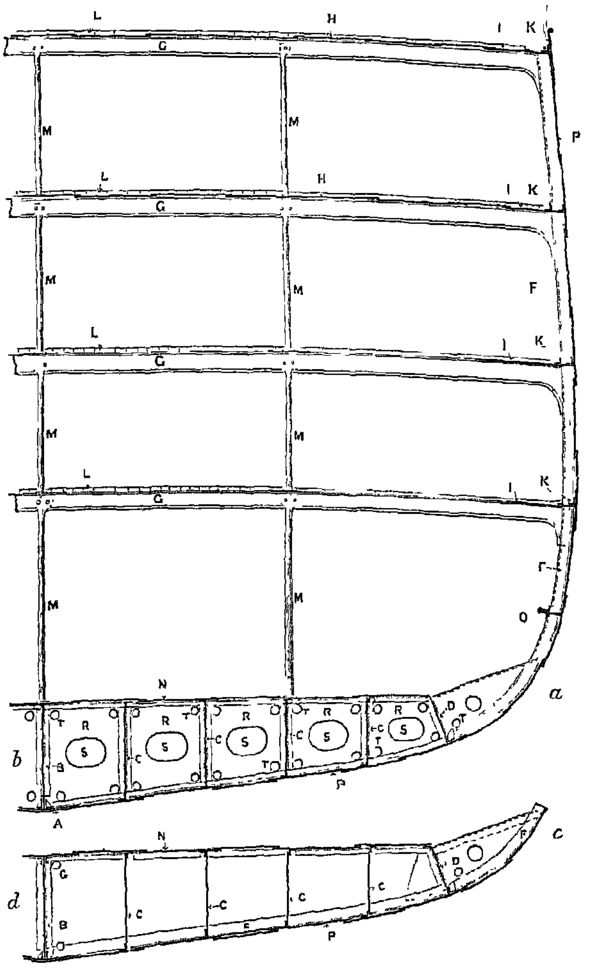

Fig. 5.—Midship Section of ss. *Scot*, illustrating the Cellular Bottom System of Construction:

a, *b*, arrangement on every frame under engines, and on alternate frames elsewhere; *c*, *d*, alternate frames in holds.

A, keel-plate; B, centre longitudinal; C, side longitudinal (analogous to keelsons in vessels with ordinary bottoms); D, wing-plate; E, bottom frame; F, side frame (reverse frame dotted); G, deck-beams; H, deck-plating; I, deck-stringers; K, stringer-angles; L, deck-planking; M, hold stanchions; N, tank top or inner bottom-plating; O, bilge keelson; P, shell-plating; R, deep-floor plates (analogous to solid floors in vessels with ordinary bottoms); S, man-holes; T, air and limber holes.

Composite Ships.—The only serious *disadvantage* attaching to steel ships is one common to them with iron ships—fouling and corrosion in actual service. The attachment and growth of marine plants and animals, which takes place more or less rapidly on iron ships in all waters, and especially in warm or tropical seas, has all along been the serious bugbear of the navigator and the shipowner. Cases are on record where a few months in tropical waters have sufficed to produce such an amount of fouling as to reduce the speed of the ship very considerably. The anti-fouling properties of copper-sheathing—which from a very early date formed an essential item in the proper fitment of a wooden vessel for sea—were so well understood that for long after iron had supplanted wood the 'composite' system of construction was followed. Ships built on this system resemble iron ships in all respects, except that they have wood-planking, keels, stems, and stern-posts; the wood-planking enabling their bottoms to be sheathed with copper. The composite system of construction found special favour in connection with ships of war and with mercantile ships for particular services, intended to keep the sea for long periods and to maintain their speed. The China clippers formerly employed in the tea trade, whose annual races home excited so much interest, were built on this system; and in the royal navy the composite system still obtains for smaller-sized vessels, and even for the larger and swifter iron and steel cruisers having an inner metallic skin. Amongst the innumerable attempts to remedy the fouling of iron ships some have been directed towards attaching protective sheathing—copper or zinc—indirectly or directly to the iron shell, but commercial and practical difficulties have defeated these efforts; and in spite of countless specifics proposed, it would seem as if frequent docking and careful coating of the hull with the most approved paints and compositions were the best protection.

The Art of Shipbuilding.—The employment of iron for constructional purposes and the simultaneous extension of the use of machinery revolutionised the art of shipbuilding. The manipulation of this malleable material and of its still more ductile successor, mild steel—especially with the aid of steam machinery—is simplicity itself compared with the elaborate hewing and fashioning of timber requisite in wood shipbuilding. Take, for example, one of the more important parts of a ship's structure, the rib or frame. In a wooden vessel it is a matter of careful and skilful workmanship to saw or hew from the rough logs approximately curved timbers, many of which have to be combined to form a single rib. In an iron ship, on the other hand, the angle-bars used for frames are simply heated in a furnace and then bent to the required curve, each frame in its complete form consisting of the simplest possible combination of angle-bars and a plate or plates for the floor. The iron-manufacturer anticipates the wants of the iron-shipbuilder, and supplies the material approximately of the very forms and dimensions in which it enters into the structure, thus diminishing the work of trimming and preparation to a minimum. Machinery too has discounted and displaced handicraft skill in the iron shipbuilding yard. Iron plates and bars are punched, sheared, drilled, planed, and bent by simple and suitable machines managed by comparatively unskilled hands. One or two skilled workmen, assisted by several unskilled labourers, can rapidly perform in iron operations corresponding to those which in wood would necessitate the handicraft skill and prolonged efforts of many trained shipwrights. Division of labour also enters into the economy of iron shipbuilding to a much greater extent than in wood shipbuilding. The shipwright, as his name implies, really builds the ship, other tradesmen merely aiding in the fittings and equipments; whereas in the case of iron shipbuilding there is no correspondingly prominent artificer of the 'all round' type, the work being apportioned among machine-aided ironworkers, joiners, and carpenters. Shipbuilding may, in these respects, be said to have lost dignity as an art. It is otherwise, however, when we regard iron shipbuilding as an industry and the modern steamship as a product of science. The rate of production is accelerated tenfold compared with what it was even in the palmiest days of wood shipbuilding; and in point of size and perfection of equipment the magnificent mail-steamers and ponderous ironclads produced almost daily from the yards of our busiest shipbuilding centres dwarf almost into insignificance the achievements of former times.

The undertaking of a new vessel in modern times originates as a general rule with the shipowner; and from his experience as to the needs of the case he submits to the professional marine architect (as distinct from the shipbuilder; in business for himself, or sometimes the exclusive servant of the shipowner) the main regulating conditions of design—e.g. the principal dimensions, the structural type, the cargo to be carried, or the speed to be attained on a given draught of water. From these and other fundamental data the architect is enabled to prepare a suitable design and a detailed specification, which the owner can lay before one or more builders and obtain prices. Even where this is the procedure adopted and a given builder has been fixed upon, there always remains a goodly amount of designing work to be done in connection with details and with the preparation of 'working-drawings' to guide the workmen in the shipyard. This necessity has existed so long, and building firms have evinced such readiness to requisition their staff of draughtsmen on behalf of owners desirous of building, that at the present day quite three-fourths of the necessary designing is willingly undertaken by shipbuilding firms who see some chance of their securing the order to build. We may follow the development of a typical modern vessel from the time she is ordered until she is 'handed over' complete to her owners, on the supposition that the whole of the work connected with her is undertaken by one firm of builders, who are also marine engineers. The first step is the preparation of 'constructional' or 'draught' plans, showing by a series of curved and straight lines the contour of the ship's hull, on three distinct planes, represented by (1) the 'sheer-plan' or longitudinal elevation, showing the lines of length and height from stem to stern; (2) the 'half-breadth plan,' showing the lines of length and breadth, or, in other words, those lines corresponding to the margin of the Decks (q.v.) as they would present themselves to an observer looking down on the skeleton of the vessel from an elevation; (3) the 'body-plan,' which shows all lines of breadth and height visible to one looking at the framework of the vessel 'end on.'

Following upon the design of the hull form or even preceding it is the preparation of a 'midship section' showing the transverse contour of the vessel amidships, and the thickness of the various parts which go towards constituting the structure (see specimen midship section shown by fig. 5). If the vessel is to be 'classed at Lloyd's'—as the majority of vessels at the present day are—in order to facilitate its insurance by the underwriters, this 'midship' or 'scantling section' is despatched to Lloyd's Registry of Shipping, with the scantlings approved for the particular class—'100 A,' '90 A,' &c.—which the owners or builders may desire. The practice of classing at Lloyd's (q.v.) is most advantageous in several ways. Not only does it serve the owner as a 'patent royal' in all subsequent negotiations connected with insuring the vessel and her cargo, but incidentally it relieves the designer and builder of a great amount of calculation and concern connected with fixing the requisite size and proper grouping of the parts constituting the structure. Elaborate codes of rules have been formulated, and are issued annually by Lloyd's (see LLOYD'S).

When once the hull form is delineated on paper, a wood model or small-scale duplicate of the hull is prepared, which, besides showing more clearly to the eye the exterior form of the ship, is available for various constructional purposes. On its surface are marked vertical lines from keel to gunwale, representing the frames at equal distances apart (21 inches in small vessels to 24 and 26 inches in large) from the stern-post to the stem. Across these, and in a longitudinal direction from stern to stem, lines are drawn representing the edges of shell-plating, which is arranged in 'strakes' analogous to the planking in a wood ship, each strake being divided throughout by 'butts' into uniform lengths of plates. The surface of the model is also marked with lines representing the decks, the transverse bulkheads, the side-ports, &c. From the model as thus prepared, and from various plans, such as deck, bulkhead, keelson, and floor plans, the draughtsman measures and orders from the makers the angle-bars, bulb-bars, plates, and butt straps. Meanwhile the vessel's lines, as delineated on paper, have been 'laid off' on the mould-loft floor full size, in which process inaccuracies due to the small-scale drawing are eliminated. From the mould-loft lines, when accurately 'faired,' moulds and templates of the several parts of the ship structure are prepared for the guidance of the workmen in the shipyard. The most important item thus prepared is the 'scrieve-board,' an immense piece of flooring on which the 'body-plan' or frame curves and other features are delineated full size by sharp lines cut or 'scrieved' in the smooth surface. This flooring is placed convenient to the angle-bar furnace and the contiguous 'bending-blocks,' massive iron slabs which form the solid flooring on which the frames, &c. are bent. On this floor the form of the frame is marked from the scrieve-boards. All over the floor are round holes, closely spaced and equidistant, into which—or those of them which fall within the line of the frame curvature—upright pins are placed with their upper ends projecting. Long angle-bars (*a*, fig. 6) of iron or steel properly heated are now drawn from the furnaces, and speedily bent round the pins to the form required, by special hand appliances. Each separate half-frame of a ship is thus fashioned to the proper curve in little more time than it takes to describe the process. It is now allowed to cool, and it is then returned to the scrieve-board to be set or adjusted with 'reverse frame,' which with the 'floor' plates go to make the ship's frame in its complete form. The three items tentatively bolted together are now taken to the building-berth, and there riveted together by hand or by hydraulic power machines, the holes for the rivets having been punched by the punching-machine partly before and partly after bending. While this has been going on, the keel has been laid on the blocks—heavy masses of wood, usually 4 to 6 feet apart and 3 to 4 feet high, their tops lying in a plane inclined to the horizon about ⅝ inch per foot. The frames as completed are hoisted up in their places, and kept in position by shores and ribbon-pieces. The stem and stern-posts are set up, and soon the work becomes general all over the vessel. The deck-beams—usually of the forms shown in *b* and *c*, fig. 6—are put up, the bulkheads, stringer-plates, and keelsons are added in due succession, and the outside shell-plates are curved, punched, fitted, and temporarily fastened with bolts and nuts ready for the busy hammers of the riveters.

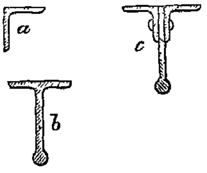

Fig. 6.

In vessels built on the cellular double-bottom principle the order of procedure is different from the above, especially in the earlier stages. The frames in this case are in three and sometimes four sectional parts. One part (when three parts are employed) forms the bottom of the vessel, and extends across and through the centre longitudinal (B, fig. 5), terminating against wing-plate D at each bilge. When four parts are used, one begins on each side the centre longitudinal B, to which it is securely attached, and ends against the wing-plate D on each bilge. The remaining two parts form both sides of the vessel, and are superimposed upon the wing-plate, and firmly bracketed to it. In construction therefore the centre longitudinal and keel are first erected, the bottom sections of the frame fixed in place, and the whole system of longitudinal and deep-floor plates completed before the side portions of the frames are erected. In other respects the procedure does not materially differ from that above outlined.

All the iron-work entering into the structure is fastened together by rivets. Holes are first punched or drilled in the plates and angle-irons, in most cases before they are put together. The holes having been made exactly to fit over each other, a red-hot rivet is received from the boy rivet-heater, and inserted through them, as in *b*, fig. 7. A workman called the 'holder-up' holds the head of the rivet forcibly in place with a heavy iron tool, while two riveters on the other side of the plate strike its point rapidly with their hammers until hammered down flush with the plating or as shown at *a*. The contraction of the rivet in cooling causes it to draw, and hold the two plates still more tightly together.

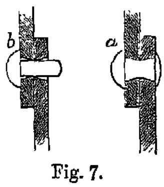

Fig. 7.

Steamships are divided throughout their length into compartments by transverse bulkheads. These partitions, like the outside shell of the vessel, are made water-tight by 'caulking'—i.e. forcing by means of blows from a hammer on a chisel-like tool the edge of one thickness of plating against the surface of the other. With the completion of the riveting and caulking of the shell and the concurrent advance of other features the vessel is ready for launching. Preparations for this highly important and critical part of the work have been proceeding simultaneously with the finishing touches to the shell. Launching 'ways' of heavy timber have been laid down parallel to the keel and at some little distance on each side of it under the bilges of the vessel, and extending into the water some distance beyond and below high-water mark. A 'cradle' is then built under the ship, the bottom of which is formed of smooth timbers, or 'sliding ways,' resting upon the 'permanent ways.' Before launching, the rubbing faces of both of the ways are well greased, and gradually the weight of the ship is transferred from the 'keel-blocks' and bilge-blocks to the cradle and ways. By a locking arrangement of the two ways the tendency of the ship and cradle to glide down the lubricated pathway is resisted until the proper moment. When this arrives (at high-water usually) the ceremony of naming the vessel takes place, the locking arrangement or 'dog-shore' is knocked away, and the vessel glides down the appointed pathway with gradually increasing velocity until checked by the resistance of the water or 'brought' to by check-ropes and weights on shore. As soon as the vessel is 'water-borne' the weight is taken from the cradle, and it floats apart in pieces, which are afterwards towed back to the shipyard.

Although the vessel is now afloat, much probably remains to be done. Frequently the greater part of the deck-planking has to be laid and caulked, and the whole of the cabin appointments, previously prepared in the joiner's shop, to be fitted up; the wood ceiling which lines the cargo-holds has to be laid, the masts have to be put on board and erected, together with the spars, sails, and rigging. In the case of a steam-vessel the propelling machinery—engines, boilers, shafting, &c.—and the various items of deck machinery—windlass, winches, steering-gear, &c., have all to be placed and properly secured on the seatings provided for them. The main engines and boilers have of course been under construction almost since the date of the order, and with their erection and fitting in the interior of the vessel, the responsibility devolving on the engineering department is more accentuated. All is at last complete: the multifarious deck-fittings, the furnishing of the saloons and state-rooms, the fitting of the electric light probably, the completion of the network of piping, the fitting of the steering gear, the placing of the compasses, and the thousand-and-one other items which go towards the thorough equipment of the vessel for sea. When at last the steamer glides out of the dock of her builders and proceeds on her trial trip, and to adjust compasses, there ensues what is not infrequently a most anxious period for the builders and engineers. In vessels where high speed, together perhaps with carrying capability on a given draught of water, is the regulating condition of design, the stipulations as to speed trials are often most exacting. The 'measured mile'—i.e. the nautical mile of 6280 feet determined by fixed marks on a straight length of coast-line—is usually the means by which a vessel's speed capabilities are ascertained; but in addition to running the mile most of the higher class steamers have to undergo tests of steaming continuously over long distances. Two, four, and sometimes more separate runs are made over the mile, half the number with and half against the tide, the object being to eliminate the tide's influence from the results. The mean time taken to each double run enables the builder to compute the rate of speed per hour of which the vessel is capable.

Scientific Qualities of Modern Steamships.—Speed, power, and dimensions almost of necessity imply stability, strength, and safety, and these several qualities are duly balanced in the magnificent ships traversing the Atlantic and other important oceans; while in the paddle and screw steamers employed in various other kinds of service—such as river, lake, and cross-channel passenger work—practical skill and scientific knowledge are equally exemplified. In the case of purely cargo and freight-carrying vessels, while fundamentally the same order of conditions obtains, there are other influences and restrictions, due to the exigencies of commerce and of economic service, which interfere with the balance of qualities. Speed, for instance, may be subordinate to economic consumpt of coal; stability may be regulated less by the ship's form and weight-distribution in the hull structure than by the amount and distribution of cargo when the ship is fully loaded; and safety or immunity from risk may be subordinated to convenience of working. The functions of the present-day designer of steamships are concerned not so much with attaining great success in any one direction at any cost as with fulfilling various and conflicting conditions of service at moderate outlay.

The attention of the shipping world has frequently been called to novelties and so-called 'new departures' in ship design and construction, but commercial prudence and industrial caution have hitherto kept their balance, and the ultimate effect of most of these 'flashes in the pan' has been to illumine and make clear the safest line of advancement. The employment of electrical energy for propulsive power—which has already met with considerable success in small craft, and for very short runs—naturally leads to speculation on the possibility of its being introduced into ocean-going vessels. In the midst of such immense and marvellous works achieved by this great force one might be excused for such speculations as to the 'ship of the future,' but we have the authority of *Engineering* (December 4, 1891) for saying that no one of the builders of the present-day Atlantic steamers entertains any belief in the probability of electricity, or indeed any other motive power, superseding steam in ship-propulsion.

Ship-producing Countries and Districts.—With the change from wood to iron, and the development of propulsion by steam instead of sails—in both of which the United Kingdom took the initiative and has maintained the lead—the iron shipbuilding industry not only chose to flourish in the country which originated it, but became localised and concentrated in the districts which, besides possessing the *sine qua non* of ready outlet to the vast ocean, are specially favoured as being the repositories of great natural wealth in the form of coal and ores. In this way the valleys of the Clyde, Tyne, Wear, and Tees have become the great centres of shipbuilding, as have also the Thames and Mersey, although the two latter rivers have for a considerable number of years been overshadowed as building centres by the immensity of their shipping. Belfast and Barrow-on-Furness are important shipbuilding centres, not alone because of large annual output of tonnage, but by reason of the number of high-class ocean steamships built there. America apart, Britain has practically done the world's shipbuilding for many years, and even now, when in America and Europe iron shipbuilding is being steadily developed and encouraged by government subsidies and otherwise, British shipbuilders are still being requisitioned by foreign shipowners. During 1891, for example, vessels possessing a total tonnage of 16,000 tons were constructed in Great Britain for German account, the tonnage built in Germany itself being 28,000 tons. Notwithstanding this dependence on foreign shipbuilders, Germany is the European country which, after Great Britain, with its colossal yearly tonnage of about 800,000, turns out the largest number of new ships year by year; Norway, at one time mistress of the seas, occupying third place. France, Italy, and America, which are endowed with a wealth of shipbuilding timber, are coming rapidly to the front with iron ships, and largely depend on home production.

In the United States shipbuilding began with fishing-boats, smaller and larger: the first ship built was the *Virginia*, 60 feet long, at the mouth of the Kennebec River in 1607. In 1640 a vessel of 300 tons was built at Salem; and soon shipbuilding was a prosperous industry in several New England ports. In 1700 New York owned 124 vessels and Boston 194, some of 300 tons. The revolutionary war was fatal to the industry; but from 1812 to 1850 wooden shipbuilding prospered exceedingly, and the American sailing-vessel reached perfection. The first China clipper was built by Webb at New York in 1841; the first three-decker by the same builder in 1849. The building of whalers, once a great New England occupation, is almost extinct. The share of the United States in the introduction of steam-power has been already recorded, as also the rivalry between the Collins Line and the British Atlantic lines. In 1847 congress subsidised mail-steamers from New York to Chagres, and from Panama to San Francisco. The Pacific Mail has sent steamers to the Sandwich Islands, Japan, China, and Australia. In 1830-61 New York, Philadelphia, Boston, and Baltimore built eighty sea-going steamers with an aggregate tonnage of 120,000 tons. America is specially famous for her river and lake steamers, the first stern-wheel paddle-boat being built by Fulton and Livingston at Pittsburgh in 1811. The first great lake steamer was built at Sackett's Harbor in 1816; and the first iron boat was built in Pennsylvania for service on the Susquehanna. New York soon took the lead in this branch, and in 1836 produced a vessel of 600 tons. Webb was the great builder of wooden ships, as afterwards of iron ones; Cramp of Philadelphia and Roach of Chester became famous for their iron and steel ships. At the outbreak of the civil war, which ruined both shipbuilding and carrying trades, Philadelphia had pushed ahead of New York; and the Delaware has been called the Clyde of America, Wilmington and Chester being also shipbuilding centres. Baltimore and San Francisco build iron steamers; and there are shipbuilding yards at Pittsburgh, St Louis, Buffalo, Cleveland, and many other places.

In 1890 the United States had shipping to the amount of 928,062 tons in the foreign trade, and in coasting, &c., 3,409,345 tons. The 15,164 sailing-vessels had a tonnage of 2,109,413 tons; the 5965 steamers, 1,859,089 tons; and with barge and canal boats, there was a grand total of 23,467 vessels of 4,424,497 tons. In the year 1889-90, 505 sailing-vessels of 102,873 tons were built; 410 steamers of 159,046 tons; 40 canal boats of 4346 tons; and 96 barges of 27,858 tons. Of the world's total—22,939,958 tons—of shipping above 100 tons register, 11,928,624 tons belonged to Britain. Figures as to the shipping and trade of the most important countries are given in the articles on those countries. In 1890 the total tonnage of vessels built in the United Kingdom was 1,197,235; in the United States, 148,178; in Germany, 102,465; in the British colonies, 44,540; in France, 34,562; in Norway, 27,153; in Holland, 26,133. The table appended, from Lloyd's Register, shows the tonnage building in the United Kingdom in 1875 and 1891.

	1875. Vessels building at September 30.				1891. Vessels building at September 30			
	Steam.		Sail.		Steam		Sail	
	No.	Tons gross.	No	Tons gross	No.	Tons gross	No	Tons gross
Steel...	..	..	..	..	249	503,015	100	179,886
Iron....	126	157,466	114	106,521	82	13,132	6	2,480
Wood .	6	1,065	203	51,122	3	160	35	3,441
Total...	132	158,531	317	157,643	334	516,307	141	185,807

The table shows that the average size of vessels built in 1891 was considerably more than twice that of vessels built in 1875. Then steel was not used for shipbuilding purposes; now it has all but supplanted iron. Then the tonnage in hand was equally divided between steamers and sailing-vessels; now the proportion of steam to sail tonnage is about three to one, although as recently as September 1890 this proportion was nine to one—a remarkable reversion in favour of sailing-ships.

Shipka, a pass in the Balkans, on the side next Roumelia, 50 miles NE. of Philippopolis and 87 miles SW. of Rustchuk on the Danube, was stoutly held by the Russians, in an entrenched camp, against the desperate assaults of Suleyman Pasha (21st to 26th August and 9th to 17th September) in the war of 1877.

Ship-money, an impost levied by Charles I. in 1634–37, which led to fierce opposition on the part of Hampden and the parliament. In old English days royal navies were raised by the levying of ships; and under the early Norman kings the ports and the counties on the coast were called on from time to time to provide ships and men to strengthen a naval force paid for by the kings. In 1626 Charles's expedition to Cadiz was largely made up of merchant-ships pressed into the royal service; but it was in 1634, when the Dutch and French navies were well able to dispute England's sovereignty of the sea, that Charles set himself seriously to the work of greatly strengthening the English navy. By the advice of Noy, the attorney-general, he issued writs to the port towns to furnish ships, but agreeing to provide the ships if the towns would equip and man them. In 1635 he demanded the like from maritime and inland counties also; agreeing as before to find the ships if money for manning and equipment were provided by the counties. Thus a strong fleet was raised and manned with money which was not sanctioned by any parliamentary grant; and much grumbling was the result. In 1637 Charles consulted the judges, and ten out of twelve declared that the king had a right to do what was necessary for the defence of the kingdom in times of danger. It was agreed that no tax could be levied without parliamentary sanction; but Charles maintained that ship-money was not a tax, but money paid in lieu of the performance of the duty incumbent on all Englishmen of defending their country. John Hampden refused to pay the 20s. levied on his estate in Buckinghamshire, and his case was dealt with by the Exchequer Chamber (for the issue, see HAMPDEN). The Long Parliament in 1640 and 1641 pronounced the levying of ship-money illegal; and the bill to this effect received the king's assent, 7th August 1641.

Shipton, MOTHER, a famous prophetess of popular English tradition, whose story has at any rate the weight of a considerable antiquity. S. Baker published in 1797 her prophecies, together with those of the Cheshire prophet Nixon, and here we gather the following circumstantial details. Ursula Shipton was born near Knaresborough in Yorkshire, in July 1488, was duly baptised as Ursula Southiel by the Abbot of Beverley, at twenty-four married Tony Shipton, a builder, and departed this life with much serenity at over seventy years of age. However, a book (1684) by the notorious Richard Head is the real source of most of the fables about her. Here we are told how Agatha Shipton was carried off and married by the devil, how she bore him an ugly impish child, enjoyed power and knowledge beyond the measure of mortals, and left many prophecies behind her. Of these the earliest known record is a pamphlet of 1641, containing formal prophecies of the death of Lord Percy and of Wolsey—her prophecy that

Wolsey should never reach York was long current, is given by Baker, and was claimed as fulfilled by the fact that Wolsey was arrested at Cawood, a few days before his formal installation as Archbishop of York. In W. Lilly's *Collection of Ancient and Moderne Prophesies* (1645) occurs 'Shipton's prophecy,' and from it we see that all her prophecies were considered as already fulfilled. Again, an extant comedy on the subject dates from about 1660. A prophecy in doggerel verse under her name was put into circulation about 1862 by Charles Hindley, on his own confession (*Notes and Queries*, April 26, 1873). These wretched lines concluded with a prophecy that the world should come to an end in 1881, which caused great anxiety amongst a few very ignorant persons in corners of England. See William H. Harrison's *Mother Shipton Investigated* (1881), in which all the facts available are excellently set forth. Mr Harrison points out, moreover, the striking likeness between the traditional Mother Shipton represented on the chap-books and the conventional Punch.

Shiraz', a city of Persia and capital of the province of Fars, much celebrated in Persian poetry for its climate, its wine and roses, and its beautiful gardens, is situated in a broad plain, 115 miles ENE. of Bushire and 35 miles SW. of the ancient Persepolis (q.v.). It is enclosed by ruined walls, and previous to the earthquakes contained many splendid mosques, bazaars, caravanserais, and other public buildings. The place has now a mean and ruined appearance, and is greatly neglected. The wine of Shiraz, which is very strong and resembles Tokay, is, however, still famous throughout the East. Rose-water is prepared in large quantities. Inlaid articles in wood and metal, glass, and woollens are made here. The city was founded in the 8th century, and from its beautiful situation and charming climate became a favourite resort of the Persian princes. In 1812 a destructive earthquake laid a large portion of it in ruins, and another in 1824, which cost the lives of 4000 of the inhabitants, completed the wreck of its prosperity. It was, however, rebuilt, and numbered 40,000 people, when a third and more terrible visitation, in April 1853, laid almost the whole town again in ruins, and caused the death of 10,000 people. It has since been partially rebuilt in a somewhat inferior style, and its pop. is now estimated at 30,000. The tombs of the poets Hafiz and Sádi, both natives of the town, exist in the vicinity.

Shire. See COUNTY.

Shiré, a river of East Africa, has its source in Lake Nyassa, and after a southerly course of 370 miles joins the Zambesi. It forms part of the chief highway to the Lakes region, and was discovered by Livingstone during the Zambesi expedition (1858-63). The navigation is obstructed by cataracts (Murchison Cataract) for 35 miles, in which the Shiré falls 1200 feet. The river passes through the heart of the Shiré Highlands, the scene of the Church of Scotland's and the English Universities' missions, and of the labours of the African Lakes Company. This district was declared British territory in 1889. See John Buchanan, *The Shiré Highlands* (Lond. 1885).

Shirley, JAMES, dramatist, was born in London, September 13, 1596, and went at twelve to Merchant Taylors' School, whence he passed in 1612 to St John's College, Oxford. Wood tells us that Laud esteemed him highly, but deterred him from seeking holy orders because of the large mole on his left cheek. He migrated, however, to Catharine Hall, Cambridge, took orders, and held for a short time a living at or near St Albans, but, becoming a Catholic, resigned it, and made his bread (1623-24) by teaching in the grammar-school there, 'which employment also,' says Wood, 'finding uneasy to him, he retired to the metropolis, lived in Gray's Inn, and set up for a play-maker.' He worked hard in his vocation, being a diligent student of his great predecessors, and Shakespeare alone has bequeathed us a larger number of regular five-act plays—there are as many as thirty-three printed in the edition of Gifford and Dyce. In 1636 or 1637 he went to Ireland, probably under the protection of Lord Kildare, but soon returned to London, where the suppression of stage-plays in 1642 ended his livelihood. For some time he attended on the Earl of Newcastle, then returned to London again to earn his bread by teaching. He contributed the address 'To the Reader' to the first folio of Beaumont and Fletcher (1647). The Restoration revived his plays, but brought him no better fortunes; and Wood tells us that he and his second wife died on the same day, distracted by the Great Fire, and were buried in the same grave, October 29, 1666.

For his plots Shirley drew upon his own inventiveness, and Dyce points out that not one, if we except that extraordinary failure, *St Patrick for Ireland*, is founded upon events of British history. Beaumont and Fletcher were his models, even more than Ben Jonson, his 'acknowledged master,' but it must be owned he has but little of the grand Elizabethan manner. Most of his plays are tragi-comedies, and his best work is ever the tragic and pathetic portions. He is chaste by comparison with his contemporaries, and his plays breathe throughout a pensive and tender beauty that touches a sympathetic reader with a charm of its own. Bright and playful fancy, sweet and flowing dialogue, honest emotion and unwrought pathos—these are the threads out of which his magic robe is woven.

His chief plays were *Love Tricks*, a bright but ill-constructed comedy, though Pepys calls it a 'silly play' (1625); *The Maid's Revenge*, a poor tragedy (1626); *The Brothers*, a comedy (1626); *The Witty Fair One*, an excellent comedy (1628); *The Wedding*, a charming and indeed exquisite comedy (1628); *The Grateful Servant*, a fine tragi-comedy, prefaced by eleven copies of verses by various friends, including Massinger (1629); *The Traitor*, his finest and also his strongest tragedy (1631); *The Changes, or Love in a Maze*, a comedy (1632); *The Bird in a Cage*, a comedy (1632, printed next year with a sarcastic dedication to Prynne, then suffering his cruel punishment); *Hyde Park*, a bright comedy, branded by Pepys as 'a very moderate play' (1632); *The Young Admiral*, specially commended by the Master of the Revels as free from oaths (1633); *The Gamester*, an admirable comedy, revived by Garrick in 1758 (1633); *The Example*, an excellent comedy, Sir Solitary Plot a happy imitation of Ben Jonson's characters of *humour* (1634); *The Opportunity*, an amusing though improbable comedy (1634); *The Lady of Pleasure*, the most brilliant of his comedies (1635); *The Imposture*, a tragi-comedy (1640); and *The Cardinal*, to the author himself 'the best of his flock,' a tragedy coloured by Webster's *Duchess of Malfi* (1641). In 1646 he printed a volume of his poems, including his masque of *The Triumph of Beauty*. As a writer of masques he is second only to Ben Jonson. Among his best was *The Triumph of Peace*, presented by the Inns of Court before the king and queen in 1633. Another, *The Contention of Ajax and Ulysses* (1659), contains the noble and solemn lyric, 'The glories of our blood and state are shadows, not substantial things.' Almost as good is the ode, 'Victorious man of earth,' in *Cupid and Death* (1653), or that beginning 'Ye virgins that did late despair' in his dull play, *The Imposture*. The only complete edition of his works is that edited by Gifford and Dyce (6 vols. 1833). There is a selection of five plays, with *The Triumph of Peace*, in the 'Mermaid' series, by E. W. Gosse (1888).

Shirwa, a lake of south-east Africa, 45 miles SE. of Lake Nyassa; length, 40 miles; breadth, 15 to 20 miles; and 1970 feet above the sea-level. On the west, between the lake and the river Shiré, Mount Zomba rises to 7000 feet. It was proved by Consul O'Neill in 1884 to have no connection with the river Lujenda, a right-hand tributary of the Rovuma. See *Proc. Roy. Geog. Soc.* (1883-84-88).

Shisdra, a town of Russia, 80 miles SW. of Kaluga, on a branch of the Oka. Pop. 11,678.

Shishak (in hieroglyphs, *Shashank*, the *Susak* or *Susakim* of the Septuagint, the *Shishak* of the Hebrew version, the *Sesonchosis* or *Sesonchis* of Manetho), the name of several monarchs of the 22d or Bubastite Egyptian dynasty (see EGYPT, Vol. IV. p. 240). Shishak I.'s name is found in the portico built by the Bubastite dynasty at the great temple of Karnak, and on several statues of the goddess Pasht, which probably came from Luxor. Jeroboam fled to Shishak from the pursuit of Solomon, who wished to kill him, and lived there during the lifetime of Solomon. On the death of this monarch Jeroboam quitted Egypt, and contended with Rehoboam for the possession of the crown. This struggle caused the division of the kingdom of David into two states, that of Israel and Judah. In the fifth year of Rehoboam Shishak marched to Jerusalem with an army of 12,000 chariots, 60,000 cavalry, and an innumerable number of infantry, composed of Troglodytes, Libyans, and Ethiopians. He took the city, the treasures of the temple, and all the gold bucklers which Solomon had made. The conquest of Jerusalem is found recorded on the monuments of Karnak, on which Shishak I. is represented dragging before the god Ammon three files of prisoners, inscribed with various names of places, amongst which are Judæa, Megiddo, Ajalon, Mahanaim, and other towns taken by Shishak in his line of march.

Shittim-wood, the name in the Old Testament for a valuable and durable wood, believed to be that of some kind of acacia—probably the *Acacia seyal.*

Shoa, a country of Africa, lying to the south of Abyssinia proper, and watered by the Blue Nile and the Hawash, but usually accounted one of the three divisions of the Abyssinian state. Area, approximately 26,000 sq. m. In physical characteristics it closely resembles the rest of Abyssinia (q.v.). The highest point in the Guraghe Mountains reaches 12,790 feet. The people, who are partly Abyssinians and partly Gallas, number about 1½ million. The present capital is Licheh (pop. 3000); but the most important place is the former capital, Ankobar (q.v.). This country was conquered by King Theodore of Abyssinia shortly after his accession (1855). On the death of Theodore's successor (John II.) in 1889 the king of Shoa, Menelek, was made king of all Abyssinia; and Shoa, like the rest of Abyssinia, is now in many particulars an Italian protectorate.

Shock. It is well known that some forms of injury, as, for example, a blow on the pit of the stomach, may occasion death without leaving any visible trace of their operation in the body; and, indeed, life may occasionally be destroyed even by sudden and powerful mental emotions. In such cases as these death is said to result from *shock*, the actual cause of death being the sudden arrest of the heart's action, consequent on the violent disturbance given to the nervous system. The effects of shock may be manifested in all degrees from the transient feeling of faintness (see FAINTING) or sickness produced by a sudden emotion, or an unexpected and unpleasant sight, &c., to the disastrous result above described. In cases of moderate severity the condition known as *collapse* is induced, in which the patient lies in a state of utter prostration, and apparently on the verge of dissolution. The face, and even the lips, are pale and bloodless; the skin is cold and clammy, and drops of sweat are often seen on the forehead. The features are contracted, and there is great languor in the general expression. There is extreme muscular debility, and the sphincter muscles sometimes relax, so that there is involuntary discharge of the contents of the bowels and the bladder. The pulse is quick, and so feeble as often to be almost imperceptible, and the respiratory movements are short and weak, or panting and gasping. The patient is in some cases bewildered and incoherent, in others drowsy, and sometimes almost insensible. In less severe cases nausea and vomiting, with hiccup, are not unfrequent symptoms; and in the case of children convulsions are often present.

When a person recovers from a state of collapse he passes into a condition termed *reaction*, which often lasts for several hours. The first symptoms of this favourable change are improvements in the state of the pulse and the respiratory actions, recovery of the power of swallowing, an increased temperature, and an inclination to move from the supine position to one side. A slight degree of feverishness then often ensues, after which the skin becomes moist, the patient falls asleep, and awakes convalescent. As a general rule, the longer the symptoms of reaction are delayed the greater is the danger, and if several hours pass without any sign of the commencement of reaction there is little hope of recovery.

The principal causes of shock in its severer forms are sudden and severe or extensive injuries, whether due to accident or operation, particularly if they involve any of the viscera, joints, or other organs abundantly supplied with nerves. 'Pain alone, when intense and protracted, has proved fatal in this way; and it appears in a case related by Sir A. Cooper that sudden relief from great agony was attended by the same untoward result. Certain poisons operate in this manner, depressing the system so suddenly and severely as to produce a state of collapse; tobacco, for example; and drastic purgatives have in some cases induced a similar condition.'

The effects of shock are aggravated by loss of blood; and hæmorrhage alone, if sudden and profuse, will produce collapse. General debility and old age favour the influence of the shock, and much depends upon the idiosyncrasy of the patient; an injury which will produce no apparent effect on one man often producing a serious and persistent impression on another.

The following are the most important points in regard to treatment: The patient should be kept in a horizontal position, with the head on the same level as the body, and he should not be raised till decided symptoms of reaction appear. The best stimulant is brandy, in moderate and carefully regulated doses, given in the form of hot brandy and water. At the same time heat should be applied to the pit of the stomach and the extremities, by means of hot flannel, hot-water tins, or, in their absence, bottles containing hot water, and other appliances. Nourishment, in the form of beef-tea, should closely follow the stimulants; the two may be combined with the greatest advantage, and as the system rallies the latter may be entirely replaced by the former. See Holmes's *System of Surgery.*

Shoddy (a provincial word, 'that which is shed') formerly meant only the waste arising from the manufacture of wool, but it has acquired a wider and much more important signification. Clippings of woollen and worsted stuffs and rags of any kind of fabric made of wool are now carefully utilised. Cuttings of new flannels, worsted cloths, and knitted textiles receive the name of *new shoddy*, and when articles made of these are worn out they are termed *old shoddy*. On the other hand tailors' clippings of milled cloths are called *new mungo*, while the material of old clothes and rags of this woollen cloth is styled *old mungo*. Both shoddy and mungo, which were formerly, to a large extent at least, waste materials, are now 'ground up' as it is termed—i.e. they are put into a machine with a revolving cylinder armed with iron spikes and having toothed rollers moving in an opposite direction. This *willy* or *devil*, as it is called, reduces the rags or clippings to short wool, which, when cleaned, oiled, and mixed with some fresh wool, is remanufactured into many different kinds of cheap fabrics, such as rugs, druggets, friezes, flannels, inferior milled cloths, &c. These, though serviceable while they last, are of course not so durable as when made of new wool. See RAGS, and WOOL.

Shoebill. See BALÆNICEPS.

Shoe-blacking. See BLACKING.

Shoeburyness, on the coast of Essex, and at the mouth of the Thames, faces the Nore, 3 miles E. of Southend and 45 of London. Its dreary marshland, purchased by government in 1842–55, has since been the seat of a school of gunnery, with artillery barracks, batteries, targets, and other appliances for experimenting on cannon. See GUNNERY.

Shoes. See BOOTS AND SHOES, HORSESHOEING.

Shola, or SOLA, the white pith of the leguminous plant *Æschynomene aspera*, a native of India. With this substance, which is exceedingly light, the natives of India make a great variety of useful articles, especially hats, which being very light and cool are in great request. Helmets made of shola are much used by the British in India.

Sholapur, a town of British India, presidency of Bombay, 150 miles by rail SE. of Poona, with important silk and cotton manufactures. An old fort and ruined walls (in part) still exist. Pop. (1891) 63,312.—The *district* has an area of 4521 sq. m. and a pop. (1881) of 582,487.

Shooter's Hill, an eminence (446 feet) in Kent, near Greenwich and Woolwich, which commands a splendid view of London.

Shooting. See GUN, GAME-LAWS, POACHING, GROUSE, DEER-FORESTS, BATTUE, PIGEON, &c.

Shore. See SEASHORE.

Shore, JANE, the famous mistress of Edward IV., was born in London, and was well brought up, and married at an early age to William Shore, an honest citizen, traditionally a goldsmith. After her intrigue with the king began her husband abandoned her, but she lived till Edward's death in the greatest luxury, enjoying great power through his favour, yet 'never abusing it,' as More tells us, 'to any man's hurt, but to many a man's comfort and relief.' Her beauty was more that of expression than of feature, and her cheeks somewhat pale, yet her face was fair beyond others, and 'there was nothing in her body that you would have changed, but if you had wished her somewhat higher.' But her greatest charm was her bright and playful wit. After the king's death she lived under the protection of Hastings, and on his death, it is said, of the Marquis of Dorset; but King Richard III., out of a pretended zeal for virtue and to make his brother's life odious, plundered her house of more than two thousand merks, and caused the Bishop of London to make her walk in open penance, taper in hand, dressed only in her kirtle. More tells us that Richard had first tried to charge her with bewitching him, literally rather than in the sense in which she had done his brother, and the reader will remember the use that Shakespeare has made of this in his tragedy of *Richard III.* Jane Shore survived her penance more than forty years, dying in the 18th year of Henry VIII. The additional horrors that she died in a ditch since called Shoreditch, and that a man was hanged for succouring her contrary to Richard's command, are completely unhistorical, however positive their ballad authority.

Percy printed from the Pepys collection 'The woefull lamentation of Jane Shore,' in wretched doggerel, ascribed to Thomas Deloney. Thomas Churchyard also wrote a poor ballad on the story, inserted in the *Mirror for Magistrates*, and Drayton has in his *England's Heroical Epistles* one from her to her royal lover, with a prose description of her beauty in the notes. Deloney's ballad is printed also in the *Collection of Old Ballads* (1723), with a miserable burlesque song on the same subject.

See 'Some Particulars of the Life of Jane Shore,' by Mark Noble, in Brayley's *Graphic Illustrator* (1834); and Sir Thomas More's fine picture in his *History of Richard III.* Nicholas Rowe's drama dates from 1714.

Shoreditch, a parliamentary borough of East London, returning two members—one for Haggerston and one for Hoxton. See TOWER HAMLETS, and LONDON.

Shoreham, NEW, a seaport of Sussex, at the mouth of the Adur, 6 miles W. of Brighton. It arose when the harbour of Old Shoreham, now a mile inland, became silted up; and it has some shipbuilding, oyster and other fisheries, and a considerable trade with France from its tidal harbour, whose piers were erected in 1819. Charles II. embarked here after Worcester for Normandy. The suspension bridge (1833), the Norman and Early English parish church, and a place of resort, the 'Swiss Gardens,' may be noticed. The parliamentary borough of New Shoreham, including since 1770 the Rape of Bramber (177 sq. m. and 42,442 inhabitants in 1881), and returning two members, was merged in the county in 1885. Pop. of parish (1851) 2590; (1891) 3393.

Shorncliffe, in Kent, 2½ miles W. of Folkestone, the seat of a military camp during the Peninsular war, and since the Crimean war of a permanent one for 5000 men.

Shorthand. The problem which inventors of systems of shorthand have attempted to solve is thus formulated by Peter Bales (c. 1547–1610), a writing-master and stenographer—'to write as fast as a man speaketh treatably.' 'This,' he says, 'may in appearance seem difficult; but it is in effect very easy, containing a many commodities under a few principles, the shortness whereof is attained by memory, and swiftness by practice, and sweetness by industry.' Although three hundred years have elapsed since this assertion was made, it has not yet been realised to the extent anticipated.

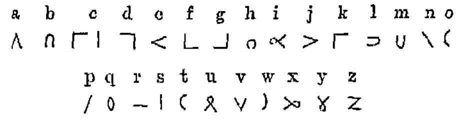
Phonography is a growth of the age, and is the lineal descendant of the 200 different systems that have been published since the appearance of the first system of modern shorthand in 1588. It carries out fully the principle which all previous systems acknowledge, but do not faithfully apply—viz. that of enlarging the ordinary 26-letter alphabet. Those systems add to the alphabet three signs for *ch*, *th*, and *sh*; but these are not all the consonants in which our alphabet is deficient. Two signs are required for *th*, as pronounced in *thin* and *then*, one for *ng* in *sing*, and one for *zh* in *pleasure* (plezhure). But the principal defect in the ordinary systems of shorthand is in their vowel notation. They contain but five signs for the five vowels, *a*, *e*, *i*, *o*, *u*, which, single and combined, represent 17 different sounds. This disparity between the sounds of the language and the means of representing them made the reading of shorthand extremely difficult and uncertain.

In the 18th century three systems were published, by Tiffin, 1750; Lyle, 1762; and Holdsworth and Aldridge, 1768; and in the 19th century five systems appeared, by Row, 1802; Towndrow, 1831; Pitman, 1837; De Staines, 1839; and Bell, 1857, based on the phonetic principle; but, excepting phonography, they were wanting in all the main requisites of a shorthand system—simplicity of construction, facility in execution, and elegance in effect.

The shorthand of the Romans, practised by Tiro, first the slave and afterwards the freedman of Cicero, was really an abbreviated longhand. The Roman letters were shorn of their just proportions, initial letters often served for whole words, and terminations, in which Latin abounds, were either abbreviated or omitted. By systematising these mutilations Tiro constructed a system of swift writing, which served him as Cicero's amanuensis in good stead, and doubtless we owe to it much of what remains to us of the writings of Cicero.

The history of shorthand properly so called, with an alphabet of simple signs as substitutes for the ordinary letters, dates from the reign of Elizabeth. Dr Timothy Bright (*c.* 1551–1615), a learned man, the author of several medical works and the compiler of an abridgment of Fox's *Book of Acts and Monuments of the Church*, in the year 1588 published *Characterie; an Arte of Shorte, Swifte, and Secrete Writing by Character.* In this ingenious work Bright claims the invention of the art of shorthand. His claim may justly be disputed, for his system is not shorthand in the present sense of the word. It is not based on a shorthand alphabet, but is a system of arbitrary marks for words: thus  *abound*, *about*, *accept*, *accuse*, *advance*, &c.

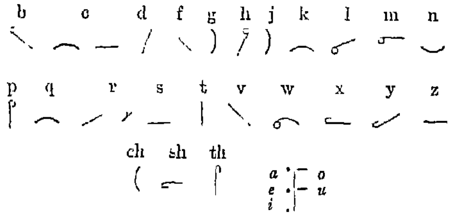
Two years after the appearance of this work Peter Bales published *The Writing Schoolmaster*. This system also was composed of arbitrary characters. In the year 1602, a little above threescore years before Wilkins published his celebrated *Essay towards a Real Character and a Philosophical Language* (1668), appeared *The Art of Stenography, or Short Writing, by Spelling Charactery, invented by John Willis, Bachelor in Divinity*. The author intimates in the title of the work the grand distinction between it and the previous attempts that had been made in the art by describing it as '*spelling* charactery,' the others having been *verbal* charactery. John Willis's alphabet is:



The inadequacy of this alphabet is proved by the fact that not one of its letters was used in the same sense by the inventors of systems in the following century, when shorthand began to be popular. Sixteen years after the publication of John Willis' system Edmund Willis published *An Abbreviation of Writing by Character* (1618). This system exhibits a considerable improvement in its alphabet, and 15 of its letters were adopted by subsequent shorthand authors.

The next name on the roll of shorthand authors deserving of mention here is that of Rich, 1654–69. His system was used by Dr Doddridge, who reprinted it for the benefit of his theological students, and strongly recommended its adoption by young persons. Mason followed in 1672–1707. The alphabet had now become much simplified. Mason's system was adopted by Thomas Gurney in 1750, and has since been known as Gurney's shorthand.

The principal shorthand authors of the 18th century were Macaulay, 1747; Angell, 1758; Byrom, 1767; Taylor, 1786; and Mavor, 1789; and in the 19th century, Clive, 1810; Lewis, 1815; Moat, 1833; Isaac Pitman (q.v.), 1837; Fancutt, 1840; Bradley, 1843. Of these systems, except Pitman's phonography, the one that has obtained the greatest amount of popularity is Taylor's, and a few private persons and reporters use it to the present day. Its alphabetic signs are well chosen, but it fails to supply signs for three consonant sounds heard in the English language, and it makes no pretension to express all the vowel and diphthong sounds. The following is Taylor's alphabet:



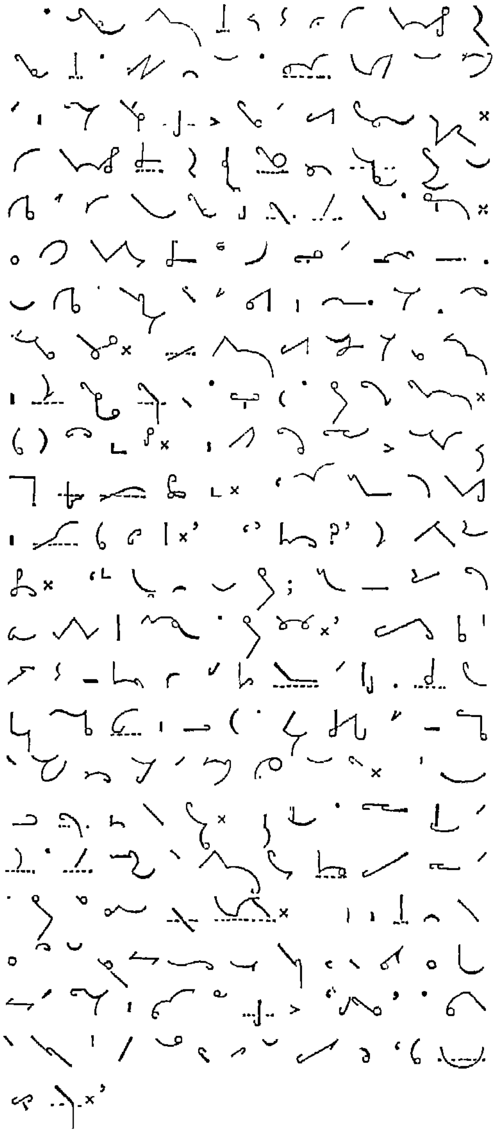
The publication in 1837 of Isaac Pitman's system of shorthand, entitled 'Phonography,' in which the stenographic signs or letters represent the *sounds* of the English language, marks a new era in the art. The legibility which this principle secures has led to the very general use of shorthand in merchants' and lawyers' offices, and in railway and ordinary correspondence; it has also promoted the establishment in England of a dozen shorthand periodicals. A vigorous propagandism, and instruction books at low prices, have aided in giving to this system its well-merited distinction above all others in public estimation. At the end of the 18th century the price of a treatise on shorthand was a guinea, and a course of lessons in the art cost five or ten guineas. In contrast with this, Mr Pitman's system is published in a compendious tabular form for a penny, and he has organised a Phonetic Society, extending throughout Great Britain and Ireland, whose members invite learners to send their lessons through the post for gratuitous correction.

Before giving a brief description of this system of shorthand we may note the conditions on which alone Peter Bales's reasonable anticipation of the future universal practice of shorthand can be realised, and then it may be seen whether phonography fulfils these conditions.

Given a language, say the English, it is required to provide signs for its expression which may be written at the rate of speech in a public assembly, which ranges from a very slow utterance of 60 words in a minute, with frequent pauses, to a rapid flow of 180 words in a minute. The average of public speaking is a mean between these extremes —i.e. 120 words a minute, or two words per second. A dexterous penman can make 180 separate simple strokes or dots in a minute. The required system of shorthand must, therefore, represent two words by three strokes (or dots), or by one and a half strokes per word. Let the reader try his hand upon such signs as

(the last two struck upward), and he will feel assured that there is no error in the conclusion to which he will be brought.

The number of pen-strokes and dots or short vowel marks in the following specimen of reporting in phonetic shorthand (*Phon. Jour.*, 1st February 1879) is 425. The number of words which these signs represent is 319, or 1⅓ strokes per word :



Key.—An enterprising reporter had heard that the late Lord Palmerston was to be present at an archery meeting in a small village in Hampshire, and he accordingly posted down to the place, and waited for something to turn up. Lord Palmerston's task was to distribute prizes to some half-dozen blushing young ladies, and the whole company present didn't number much above a score. His lordship performed the task with his usual grace and good humour, giving the young ladies a paternal pat on the head, but making only the most commonplace observations. Our reporter waited anxiously until, to his horror, he saw the proceedings brought to a close without a speech from the Premier. This was more than he could stand. He rushed from his corner to the noble lord, who was getting out of the room as fast as he could : 'My lord, I beg your pardon, but really this will not do.' 'What do you mean?' was the reply of the astonished statesman. 'Why, you've made no speech; I've come all the way from London to report it, and I must have a speech of some sort' Whereupon it is on record that the good-tempered old gentleman turned back, and detained the audience for twenty minutes while he gave them a genial dissertation on the good qualities of English women in general, and Hampshire lasses in particular. On another occasion, however, he made up for this. He was attending an agricultural dinner, and saw a large gathering of reporters, for the times were critical, and a speech of his certain to be valuable. But he had made up his mind not to speak—no man knew better when to hold his tongue—and accordingly he slyly sent down to the 'gentlemen of the press' a slip of paper, on which, in his bold, round hand, were the words : 'This fish won't bite !'

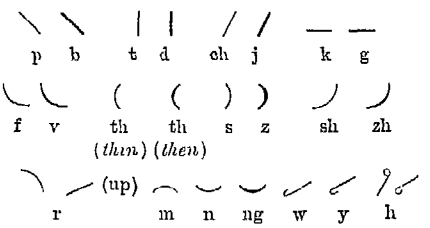
We have seen that the pen can produce 1⅓ strokes per word uttered at the rate of 120 per minute. The pen is therefore ahead of the speaker, and in a burst of oratory could record 200 words in a minute. In this calculation the reporter has the further advantage that this estimate is based on the number of *separate* strokes which the pen can make in a minute, whereas *joined* strokes can be written more rapidly than single ones : thus

take less time than

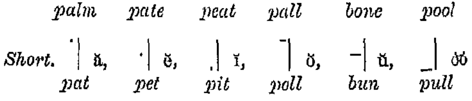
&c. In the above specimen only 130 words are written by single strokes, and the remaining 295 words or phrases (for several words are often linked together in one shorthand outline) are composed of from two to four strokes combined in one stenographic form.

Words can be recognised, either in longhand or shorthand, by their consonants alone; and the simple strokes employed in shorthand to represent the consonants may be placed in three positions, *above*, *on*, or *through* the real or imaginary line on which the writing is placed. The twelve simple or pure vowels and five diphthongs in the English language may be arranged in three classes, according to the nature of the sounds, as below. The vowel of any given word, or rather the class of vowels to which it belongs, may therefore be understood by the *position* which the consonant part of the word takes with respect to the line. The alphabet of phonography is :

CONSONANTS.



VOWELS.



Long. ah, eh, ee, aw, oh, ōō
palm *pate* *peat* *pall* *bone* *pool*
Short. ă, ĕ, ĭ, ŏ, ŭ, ŏŏ
pat *pet* *pit* *poll* *bun* *pull*

DIPHTHONGS.

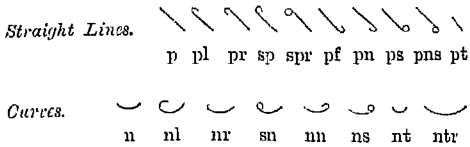
The vowel and diphthong signs are the dots, dashes, and small angular marks; the upright stroke to which they are placed (the shorthand letter *t*) is introduced to show the *position* in which the vowel-sign is written with respect to *all* consonants. These 17 vowel-signs may be distributed into three classes, all the sounds in each class having a common characteristic; thus :

Class 1.—Ah, ă; au, ŏ; ei, ai, oi = 7, in each of which, except *ei*, the broad sound of *ah* or *aw* is heard.

Class 2.—Eh, ĕ; oh, ŭ = 4, intermediate sounds between *ah* and *ee*, and between *aw* and *oo*.

Class 3.—Ee, ĭ; o̅o̅, ŏŏ; eu, ou = 6, in each of which the close *ee* or close *oo* predominates.

By adding a hook or small circle to the consonants, by halving, and by lengthening, double and treble letters are produced on the following plan :



This principle is applicable to all the consonants, and conduces to the brevity of the system.

The shorthand letters, both vowels and consonants, are employed first as component parts of words, and secondly each letter is made the representative of some common word in which the letter is prominently heard; thus \ *p* represents *up*, | *t* stands for *it*, / *ch* for *which*, — *k* for *come*, \ *ŏŏ* for *to*, &c.

The most frequently occurring words, *the*, *and*, *of*, *in*, *to*, &c., are selected for this distinction, and are called grammalogues, or letter-words; and the shorthand letters when thus employed are logograms or word-letters. In the 'learners' style' of *phonography only 50 grammalogues are used; in* the ordinary or 'corresponding style' there are 150 (which amount to one-half of the language on common subjects); and in the 'reporting style' the number is largely increased, for every short word becomes a grammalogue on the principle of omitting its vowel and writing the consonant form *in position* with respect to the line, *above*, *on*, or *below*, to denote a vowel of the first, second, or third class.

A remarkable impetus has been given to the general cultivation of shorthand by the celebration of the tercentenary of Bright's system and the jubilee of Pitman's phonography at the first International Shorthand Congress, held in London in 1887, followed by the introduction of shorthand as a subject to be taught in elementary schools and technical classes in Great Britain. The second congress was held at Paris in 1889. Many systems are used by French writers, the best known being those of Prévost (based on Taylor) and Duployé, in which the vowels are joined to the consonants. The third congress, at Munich in 1890, included special gatherings of disciples of Gabelsberger, whose system—a script one, having the slope of ordinary longhand—is largely used in Germany, Austria, Hungary, Sweden, Denmark, and Italy. The fourth congress, held at Berlin in 1891, included a special gathering of writers of the Stolze school (a modification of Gabelsberger), extensively employed in north Germany. In the United *States and Canada several persons have published* Mr Pitman's phonography. Benn Pitman, a brother of the inventor, and A. J. Graham published the English phonography of 1856, when the old vowel scale was used, and have introduced slight modifications of some parts of the system. In 1858 the vocalisation was changed to that at present used, which J. E. Munson and Longley have adopted, and which introduced some very slight changes in one or two consonants that they might secure copyright in America.

Pitman's phonography was adapted to the Japanese language in 1879, and is employed for reporting the Diet. It has also been adapted to the Hindu and Malagasy languages, and adaptations to the Welsh, French, Italian, German, *Dutch, and Spanish languages appeared between* 1887 and 1892.

See Isaac Pitman's *Phonographic Teacher*, and his *History of Shorthand* (3d ed. 1891), which describes the ancient systems and 250 English systems; Thomas Anderson's *History of Shorthand* (1882), including the Continental and leading English systems, and his *Shorthand Systems* (1884); and works by Dr Westby-Gibson (1882), J. E. Rockwell, J. W. Zeibig (Dresden, 1878), and H. Moser (Leip. 1889 *et seq.*).

Shorthouse, John Henry, was born at Birmingham in 1834, was educated at private schools, and settled as a manufacturer in his native city. In 1881 the extraordinary popularity of his romance, *John Inglesant* (previously printed for private circulation), carried his name over England. The book was written in fine, delicate English, and revealed a subtle and sympathetic insight into old-world phases of the spiritual mind, but was invertebrate in structure, its second half at any rate anything rather than a novel. It was followed by *The Little Schoolmaster Mark: a Spiritual Romance* (1883-84); *Sir Percival: a Story of the Past and the Present* (1886); *A Teacher of the Violin* (1888); *The Countess Eve* (1888); and *Blanche, Lady Falaise* (1891). These stories all lack substance, his figures being more shadows than men and women, but the style, though in later books somewhat over-refined, continues to please his admirers. He has contributed a few articles to the magazines, and wrote the article on George Herbert in the present work.

Short-sightedness. See Eye, p. 515.

Shoshone Falls (pron. *Shoshonee'*), on the Snake (q.v.) River, in southern Idaho, about 950 feet wide, and with a clear leap of 210 feet (that of Niagara is under 170 feet). The river runs in a deep gorge between walls of volcanic rock, 1000 feet high at the foot of the falls, and the head of the falls is in the form of a semicircle. Four miles higher up are the Little Shoshone Falls, two nearly equal cataracts divided by a great rock, and falling 182 feet. See the *Century Magazine*, April 1890.

Shoshones, a family of American Indians (see Vol. I. p. 226), also known as Snakes, living, since 1805 at least, to the west of the Rocky Mountains; they are now on three reservations, two in Idaho (over 2100), one in Wyoming (900)—and scattered through Nevada, Utah, and north-western Idaho (perhaps 1400 altogether). Missions have been started by the Episcopalians, Roman Catholics, and others. Though most are inoffensive, some of the bands are fierce and warlike, and hostilities ceased only in 1867, after an expedition had destroyed a great part of their braves and stores.

Shoshong, the capital of the Bamangwato tribe, and the largest native town in South Africa, is in British Bechuanaland, at the base of the Mangwato Hills, not far from the north-west frontier of the Transvaal. Connected by telegraph *with Kimberley (a railway is projected), Shoshong* (Khama's town) is a great trade centre; three routes from the Cape Colony enter the town, and three start hence for the interior—to Matabeleland, the Zambesi, and Lake Ngami. The exports are chiefly ostrich feathers, ivory, and skins, Manchester piece goods and Sheffield hardware are among the imports Pop variously stated at 15,000 to 30,000—the former the more likely

Shot is the term applied to all solid projectiles fired from any sort of firearms; those for cannon and machine guns being of cast iron or steel, those for small arms of lead Solid shot of more than 3 lb weight are no longer used as artillery projectiles except where the armament is obsolete (smooth bore or Armstrong guns) Even the Palliser chilled shot for piercing armour is not quite solid, having a small internal cavity *Bar shot* were two discs of iron connected by a bar, and used formerly to destroy the rigging and spars of ships *Chain shot*, for the same purpose, were two round shot connected by a chain *Case shot* (q v) or *canister* is used with all guns to ward off a sudden attack, as of cavalry or of boats, it consists of a tin cylinder fitting the bore of the gun, and filled with bullets *Grape shot* is obsolete It consisted of small iron balls (1 lb to 2 lb weight) held together on a spindle by canvas or by iron plates so as to be easily inserted in the gun

Small shot for sporting purposes is of various sizes, from buck shot, nearly as large as peas, to dust shot It is made by dropping molten lead through a colander in rapid motion from a considerable height into water The lead falls in small globular drops through holes varying in size according to the denomination of the shot, No 0 requiring holes $\frac{1}{5}$th inch in diameter, No 9 $\frac{1}{17}$th inch A small portion of arsenic is melted with the lead to harden it, and the fusion in the colanders is maintained by those vessels being surrounded by burning charcoal The fall through the air enables the lead to cool and harden before taking its plunge The smaller sizes require less fall than the larger—100 feet suffices for sizes Nos 4 to 9, the larger sorts demand 150 feet The highest shot tower is at Villach in Carinthia, where there is a fall of 249 feet After cooling, shot is sifted in successive sieves to separate the sizes Misshapen shot are found by their inability to roll down an inclined plank, and finally the whole are polished by rotary motion in small octagonal boxes, in which a little plumbago has been thrown

Shotts. See ALGERIA ; SAHARA, Vol IX p 76

Shoulder-joint, an enarthrodial or ball and socket joint The bones entering into its formation are the humerus or arm bone (see ARM) and the scapula or shoulder blade The former has already been described the latter is a flat triangular bone which is indirectly attached to the trunk by articulation with the clavicle When the arm hangs by the side the scapula covers the ribs posteriorly from the second to the seventh or eighth inclusive It presents a posterior surface or *dorsum*, an anterior surface or *venter*, three borders, three angles, and certain outstanding processes

The figure represents a posterior view of the scapula It is divided into two unequal parts, the supra spinous fossa (1) and the infra spinous fossa (2), by the spine (10), a crest of bone commencing at a smooth triangular surface (11) on the internal border, and running across towards the upper part of the neck of the scapula (8), after which it alters its direction, and projects forwards so as to form a lofty arch, known as the acromion process (12), which overhangs the glenoid cavity (6), or receptacle for the head of the humerus The acromion obviously serves to protect the shoulder joint, as well as to give great leverage to the deltoid muscle which raises the arm From the upper part of the neck (8) there proceeds a curved projection termed the coracoid process, it is about 2 inches long, and gives attachments to several muscles. The upper border of the scapula presents a notch (4), which in the recent state is bridged over by a ligament, and gives passage to the supra scapular nerve

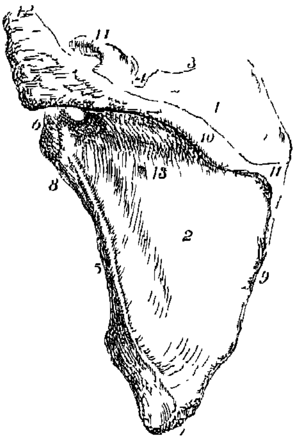


Fig 1 —Posterior View of the Left Scapula

The parts designated by the figures 1, 2, 4, 6, 8, 10, 11, 12 are sufficiently described in the text 3 is the superior border, 5, the external or axillary border, 7, the inferior angle, 9, the internal or vertebral border 12 the acromion process, 13, one of the nutrient foramina, 14, the coracoid process

The large globular head of the humerus is received into the shallow glenoid cavity of the scapula, an arrangement by which extreme freedom of movement is obtained, while the apparent insecurity of the joint is guarded against by the strong ligaments and tendons which surround it, and above by the arched vault formed by the under surface of the acromion process. As in movable joints generally, the articular surfaces are covered with cartilage, and there is a synovial membrane which lines the interior of the joint The most important connecting medium between the two bones is the capsular ligament

The shoulder joint exhibits the following varieties of motion (1) flexion, to a great extent, (2) extension, in a much more limited degree, (3) adduction, in an oblique direction, forwards and inwards, (4) abduction very freely, (5) circumduction, and (6) rotation slightly

The morbid affections of the shoulder joint may be divided into those arising from disease and those dependent on an accident The most common diseases are acute and chronic inflammation of the joint, which often terminate in its anchylosis or immobility The principal accidents are fractures and dislocations There may be fracture (1) of the acromion process, or (2) of the coracoid process, or (3) of the neck of the scapula, or (4) of the superior extremity of the humerus, or two or more of these accidents may be associated. Again, the head of the humerus may be dislocated from the glenoid cavity as the

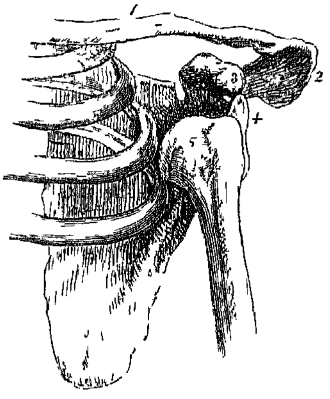

Fig 2 —Dislocation of the Shoulder joint downwards

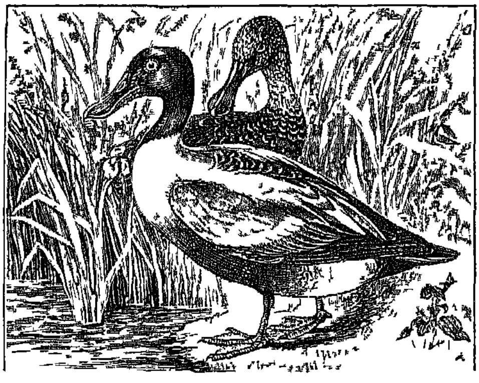
1, the clavicle 2, the acromion process, 3 the coracoid process, 4, the glenoid cavity, 5 the head of the humerus lying in the axilla result of accident in three different directions—viz (1) downwards and inwards into the axilla, which is by far the most common form, (2) forwards and inwards, and (3) backwards on the infra spinous fossa, or the dorsum of the scapula. The first of these varieties is of very common occurrence, and everybody should know how to recognise, and even (in an emergency) to treat it. The bones are in the position shown in the figure; the arm is lengthened, a hollow may be felt under the acromion, where the head of the bone ought to be, the shoulder is flattened, the elbow sticks out from the side, and cannot be made to touch the ribs, and the head of the bone can be felt if the limb be raised, although such an attempt causes great pain and weakness. The methods of treating such a case are discussed at DISLOCATION. The scapula may also be fractured in any of its parts as the result of direct violence, and its inferior angle may slip from its natural position.

Shovel, SIR CLOUDESLEY, a brave but ill fated admiral, was born of poor parents, about 1650, most probably at Clay, a Norfolk fishing village. Here he was apprenticed to a shoemaker, but he ran away to sea, and soon rose by his remarkable ability and courage through the grades of cabin boy and seaman to the quarter deck. He served as lieutenant under Sir John Narborough in the Mediterranean (1674), burned four pirate ships under the walls of Tripoli, commanded a ship at the battle in Bantry Bay (1689), and was soon after knighted for his conduct. In 1690 he rose to be rear admiral of the blue, and took an active part in the battle off Beachy Head, two years later, as rear admiral of the red, he supported Admiral Russell heroically at La Hogue, and himself burned twenty of the enemy's ships. He was sent to Vigo in 1702 to bring home the spoils of Rooke, next served under that hero in the Mediterranean, and led his van at Malaga. In January 1705 he was made rear admiral of England. That year he took part with Peterborough in the capture of Barcelona, but failed in his attack on Toulon in 1707. On the voyage home his ship, the *Association*, struck a rock off the Scilly Isles, on the foggy night of the 22d October 1707, and went down with 800 men on board. Four vessels of his squadron perished with as many as 2000. Sir Cloudesley Shovel's body was washed up next day and buried in Westminster Abbey.

Shoveler (*Rhynchaspis* or *Spatula*), a genus of birds of the duck family, Anatidæ, having the hind toe small, free, and unlobed, and remarkable for the expansion of the end of the mandibles in adult birds, particularly of the upper mandible. The lamellæ of the mandibles are long and very delicate. The legs are placed near the centre of the body, so that these birds walk much more easily than many of the ducks. The Common Shoveler (*R clypeata*) is smaller than the wild duck, but rather larger than the widgeon. The shoveler is a visitant to the British Isles, especially during cold weather. A few remain all the year. It is widely distributed over North Africa, Europe, Asia, and North America. It is reported as having been found in Australia. Its nest is made of fine grass, with a lining of down, on dry ground on the borders of rushy lakes. The eggs, from eight to fourteen in number, are of a pale greenish buff colour. Its food consists of grasses, worms, slugs, snails, insects, and small crustaceans. Its flesh is well flavoured and very highly esteemed. The bird is often called Broad bill.



The Common Shoveler (*Rhynchaspis clypeata*), male and female

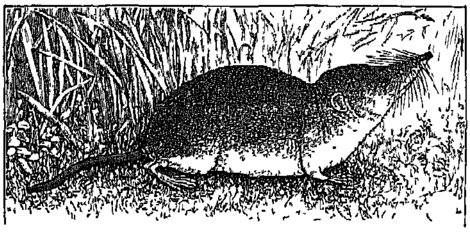
Showers of Fishes occasionally fall in different parts of the world, exciting great astonishment. Instances of this kind have occurred in Britain. On one occasion a shower of small three spined sticklebacks fell near Merthyr Tydvil in Wales, sprinkling the ground and housetops over a large area. If caught up by a whirlwind from any of the brackish ponds near the sea, in which this species of fish abounds, they must have been conveyed through the air a distance of almost thirty miles. Another similar instance occurred at Torrens, in the Isle of Mull, in which herrings were found strewed on a hill five hundred yards from the sea, and one hundred feet above it. Such downfalls are more common in tropical countries. In India a shower of fishes varying from a pound and a half to three pounds in weight has been reported. Sometimes the fishes are living, more frequently they are dead, and sometimes dry or putrefying. They are always of kinds abundant in the sea or fresh waters of the neighbourhood. The occurrence of the phenomenon is readily explained by the partial vacuum and strong up draught produced in the centre of a whirling column of air like that of a Tornado (q v). Such a whirling column in passing over the surface of a lake or river or of the sea may suck up a considerable quantity of water along with any living creatures that may be in it. This may be carried for a considerable distance, and is discharged as a waterspout or cloudburst when the rotational energy of the whirl is expended. Showers of frogs (when authenticated) are a similar phenomenon. Showers of dead flies have also been reported. The analogous showers of 'sulphur' or of 'blood' are produced by wind borne pollen from pine trees, or minute organisms of fungoid nature and bright red colour. In the latter cases the organic particles probably play the part of dust in causing the rain drops to form. See BLOOD RAIN.

Shrapnel Shell. See SHELLS.

Shreveport, the second city of Louisiana, capital of Caddo parish, on the west bank of Red River (here spanned by an iron bridge of 1200 feet), at the intersection of four railways, and 328 miles by rail NW of New Orleans, with which it has also regular steamboat connection. It ships cotton (125,000 bales yearly), hides, wool, and tallow, contains planing and saw mills, foundries, machine shops, breweries, and manufactories of cotton gins, cotton seed oil, soap, ice, carriages, &c. Pop (1880) 8009, (1890) 11,979.

Shrew (*Soricidæ*), a family of insectivorous mammals closely resembling, in general form and appearance, the true mice and dormice, but in reality widely differing from and not to be confused with those rodents. The shrews have the head small, muzzle long and pointed, eyes small but well developed, external ears usually small; body mouse-like, covered with hair; limbs short, nearly equal in size, the feet not adapted for digging; tail nearly naked and scaly. The teeth vary in number from twenty-eight to thirty two; the formula i. $\frac{v}{1}$ c. $\frac{1}{1}$ p. $\frac{v}{1}$ m $\frac{3}{3}$ shows the numbers of teeth so far as they are constant, *v* meaning that the incisors and premolars in the upper jaw vary in different species. Along the sides of the body, or at the root of the tail, are peculiar glands, which secrete a fluid of a very strong odour. The shrews are very widely distributed, being found over North America and the whole of the eastern hemisphere except Australia. The Oriental region has twenty-eight species, the Nearctic twenty-four, the Ethiopian eleven, and the Palæarctic ten. The classification of the shrews is a matter of extreme difficulty. The family is said to consist of one genus, eleven sub genera, and about sixty-five species.

The Common Shrew (*Sorex vulgaris*), found in the British Isles and over the whole continent of Europe, has a body about 2⅝ inches long, the fur being generally reddish gray above and grayish below, and a tail about 1⅝ inch long, four-sided with the angles rounded off, and not tapering. It abounds in dry fields, gardens, and hedge banks, feeding chiefly on insects, worms, and slugs. It burrows and makes long runs just under the surface of the ground. It is very pugnacious, and two shrews rarely meet without one of them being killed and eaten. Its natural enemies are moles, weasels, owls, and cats; but although killed by these it is not always eaten by them. Great numbers of shrews are often found dead in autumn without apparent cause, a circumstance as yet unexplained. The shrew breeds in spring; the female brings forth five to seven young in a nest of soft dry herbage in a hole in the ground. Though harmless and inoffensive, the shrew has long been regarded with dread and aversion (see White's *Natural History of Selborne*, Letter xxviii.). The Lesser Shrew (*S. pygmæus*), another British species, closely allied to the common shrew, but with a proportionately longer tail and white on the under parts of the body, is the smallest British mammal. The Water Shrew (*Crossopodus fodiens*), larger than the common shrew, is not known to occur in Ireland, but is found in Great Britain and over the whole continent of Europe as far north as the shores of the Baltic. Though not absolutely confined to the water-side, it prefers to live there, where it forms its dwelling as a burrow in a soft bank. It feeds chiefly on aquatic insects, molluscs, crustaceans, fish spawn, and even large fish. The Garden Shrew (*Crocidura aranea*) is common over almost the whole of Europe, but does not occur in Sweden or in the British Isles. The Tuscan Shrew (*C. etrusca*), found in the south of Europe, from France to the Black Sea, and also in the north of Africa, has a body only about an inch and a half long and a tail about an inch, and is the smallest living mammal. The Rat-tailed Shrew (*C myosura*), known in India as the Musk shrew or Musk-rat, is about 6 inches long, and has a strong musky odour. The Musk rat of Ceylon (*Sorex kandianus* or *serpentarius*), a smaller form, is found in Southern India and Ceylon. Two very interesting species have been brought from Tibet—the Tibetan Water Shrew, with sucking discs on the under surfaces of its feet; and the Tailless Shrew (*Anurosorex squamipes*), with a body like a mole, ears entirely concealed, eyes almost imperceptible, and feet short and scaly.



The Common Shrew (*Sorex vulgaris*).

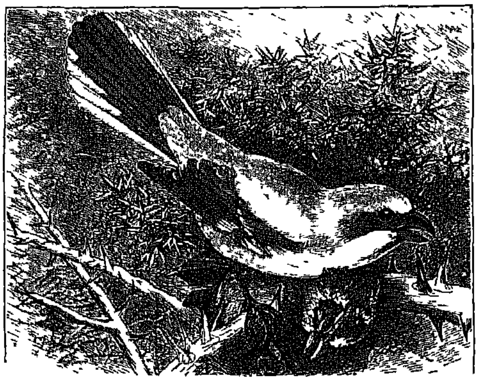
Shrew Mole (*Scalops*), a genus of insectivorous mammals of the family Talpidæ, very closely allied to the Moles (see MOLE). The tail is short and naked; the muzzle is long and slender, the nostrils looking forwards and upwards on the oblique slope at the end of the snout; the eyes are very small and are hidden in the fur. The teeth are peculiar in form; their number is represented by the formula i. $\frac{3}{2}$, c. $\frac{1}{0}$, p $\frac{3}{3}$, m. $\frac{3}{3}$. The feet resemble those of the common mole, but the toes of the hind feet are webbed. All the species are American. The Common Shrew Mole, or simply Mole (*S. aquaticus*), is found everywhere in the United States east of the Mississippi. The Prairie Mole or Silvery Shrew Mole (*S. argentatus*), about 7 inches long, is found on the western prairies as far eastwards as Ohio and Michigan. The Texan Shrew Mole (*S. latimanus*), larger in size and possessing broader fore-feet than any other species, is found in Texas and Mexico. Two other shrew moles have been placed in a separate genus: one, Brewer's Shrew Mole (*Scapanus breweri*), closely resembling the common mole externally, but agreeing in its dentition and habits with the star-nosed mole, inhabits the eastern United States; the other, the Oregon Shrew Mole (*Scapanus townsendii*), is found plentifully on the banks of rivers on the Pacific coast.

Shrewsbury, the county town of Shropshire, on the Severn, 36 miles SSW. of Crewe, 42 W. by N. of Birmingham, and 163 NW. of London. The river here makes a serpentine curve round a hilly peninsula, and is spanned by the English Bridge (rebuilt 1774) of seven arches, the Welsh Bridge (rebuilt 1795) of five, and the iron bow-and-girder Kingsland Bridge (1882), which lead to the suburbs of Abbey-Foregate, Coleham, Frankwell, Castle-Foregate, and Kingsland. With its steep, narrow streets, and its wealth of black and white half-timbered houses, Shrewsbury is picturesque as very few English towns. Its Norman castle, built by Roger de Montgomery, still stands, though greatly modernised; and coeval with it is Holy Cross or Abbey Church, belonging to a Benedictine abbey (1083). Of the other eight Anglican churches the chief is St Mary's, Norman to Perpendicular in style, with a Jesse window, the tomb of Admiral Benbow, and a spire 222 feet high. Noteworthy also are the Roman Catholic church (1856), by Pugin; the council-house (1501-60), where Charles I. stayed in 1642, and James II. in 1687; the old market-house (1595); the new market-hall (1868); the shire-hall (rebuilt 1836, and again, after fire, 1883); the corn exchange (1869); the post-office (1877); the county infirmary (1747–1830); the eye, ear, and throat hospital (1881); the 'Raven' Hotel, where Farquhar in 1704 wrote the *Recruiting Officer;* the 'Quarry,' a pretty park of 23 acres, with its lime-tree avenue (1719); a Doric column (1816) to Lord Hill, 134 feet high; and a bronze statue (1860) by Marochetti of Clive. The county museum and a free library now occupy the old buildings (1630) of the grammar-school, which was transferred to a fine new site of 26 acres (now 50 acres) in 1882, since which time the number of the boys has increased from 170 to over 300. Founded by

Edward VI. in 1551, though not actually opened till 1562, and augmented by Queen Elizabeth in 1571, this school was recognised as one of the seven great public schools in the Public Schools Act of 1868, and owes its greatness partly to its rich endowment (£3100 per annum), but still more to the exertions of two successive headmasters, Dr Samuel Butler (1798–1836), afterwards Bishop of Lichfield, and Dr Kennedy (1836–66). Among its alumni have been Sir Philip Sidney, Fulke Greville, Wycherley, Judge Jeffreys, the Marquis of Halifax, Charles Darwin, Bishop Fraser of Manchester, Archbishop Thomson of York, Viscount Cranbrook, the Right Hon. H. C. Raikes, and such famous scholars as Professor B. H. Kennedy, F. A. Paley, Professor Munro, R. Shilleto, and Professor Mayor. Glass-painting, malting, iron-founding, and the manufacture of agricultural implements are leading industries; and the brawn and 'Shrewsbury cakes' made here have long been held in esteem. Chartered by Richard I., the borough returned two members from Edward I.'s reign till 1885, when the representation was reduced to one. Pop. (1851) 19,681; (1881) 26,481; (1891) 26,967. The Cymric *Pengwerne* ('alder hill'), after its capture in 778 from the king of Powys by Offa of Mercia the place changed its name to *Scrobbesbyrig* ('town in the wood'), of which the modern name is a corruption. Thenceforward it has figured often in history, having been visited by most of the English kings, and repeatedly besieged—e.g. by Llewellyn (1215) and the parliamentarians (1644). In the battle of Shrewsbury, fought at Battlefield, 3 miles NE., on 21st July 1403, Henry IV. (q.v.) routed Hotspur and his confederates. For the earls of Shrewsbury, see TALBOT, and SHEFFIELD.

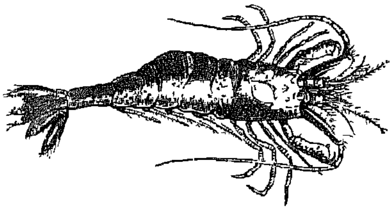
See works by T. Phillips (1779), H. Owen and J. B. Blakeway (1825), H Pidgeon (1857), and W. Phillips (1878)

Shrike (*Lanius*), a genus of passerine birds having the bill short and compressed, the upper mandible curved and with a prominent tooth, the base of the bill covered with hairs directed forwards, wings of moderate length, and very powerful feet. They are found in all parts of the world except in South America. They are called Butcher-birds from the habit, common to many species, of impaling their prey upon thorns. The food consists chiefly of insects, but often also of mice, frogs, lizards, and small birds. The Great Gray Shrike (*L. excubitor*) visits the British Islands in autumn and winter, but has not been known to breed. It is one of the largest species, its length being 9 to 10 inches. The back is of a light gray colour, wing and tail feathers black tipped with white, bill and legs brownish black. The Lesser Gray Shrike (*L. minor*) has also been seen in England; but the commonest British species is the Red-backed Shrike (*L. collurio*), which breeds in wooded districts in England and Wales, and occasionally in the south-east of Scotland. The nest is made of twigs and roots, neatly lined with wool and hair. Only one brood is reared, and the birds usually migrate in August. The males of this, and of some other species, have considerable power of song. In Australia the shrikes are represented by the nearly allied Thickheads (Pachycephala), which abound in the forests throughout that continent and Oceania (see BUTCHER-BIRD).



Great Gray Shrike (*Lanius excubitor*).

Shrimp (*Crangon*), a genus of crustaceans, of the order Decapoda, allied to lobsters, crayfish, and prawns. The form is elongated, tapering, and arched as if hunch-backed. The beak is very short, affording a ready distinction from prawns. The forceps are comparatively small. The whole structure is very delicate, almost translucent; and the colours are such that the shrimp may readily escape observation, whether resting on a sandy bottom or swimming through the water. For the change in colour on boiling, see PIGMENTS, Vol. VIII. p. 174. The quick darting movements, like short leaps, betray them to any one who looks attentively into a pool left by the retiring tide on a sandy shore. When alarmed they bury themselves in the sand by a peculiar movement of their fanlike tail. The Common Shrimp (*C. vulgaris*) is very abundant on British and other European coasts wherever the shore is sandy. It is about 2 inches long, of a greenish-gray colour, dotted with brown. It is in great esteem as an article of food, and is generally taken by a net in the form of a wide-mouthed bag, stretched by means of a short cross-beam at the end of a pole, and pushed along by the shrimper wading to the knees. Sometimes a net of larger size is dragged along by two boats. The Skeleton-shrimp or Spectre-shrimp is a small crustacean of the family Caprellidæ (as *Caprella linearis*). The Brine-shrimp (q.v.) is the subject of a separate article. The Fresh-water Shrimp is treated at GAMMARUS.



Common Shrimp (*Crangon vulgaris*).

Shrine, a case or reliquary for containing the Relics (q.v.) of saints and martyrs.

Shropshire, or SALOP, a West Midland county of England, on the Welsh border, bounded by the counties of Cheshire, Stafford, Worcester, Hereford, Radnor, Montgomery, and Denbigh. It measures 50 miles by 41, and has an area of 844,565 acres or 1319 sq. m. The Severn, entering from Montgomeryshire, winds 55 miles across the interior, dividing Shropshire into two pretty equal portions, and being joined here by the Tern, whilst a lower tributary, the Teme, traces much of the southern boundary. Ellesmere (116 acres) is the largest of several lakes. The northern and eastern portion, to the left of the Severn, is level with the exception of the isolated Wrekin (1320 feet), and is occupied by the New Red Sandstone. The south-western portion, belonging to the Old Red and earlier formations, is rugged and mountainous, and in the Clee Hills attains 1805 feet. Coalbrookdale is the chief of five coal-fields, and the mineral wealth also includes iron, lead, limestone, and freestone. The soil is variable, but generally fertile and well cultivated, so that only about one-seventh of the whole area is waste, whilst woods and plantations cover 71 sq. m. and orchards 4000 acres. Much attention is paid to live-stock, the cattle exceeding 150,000 and the sheep 430,000. The county, whose council has 68 members, is divided into 14 hundreds and 253 civil parishes. It contains the parliamentary borough of Shrewsbury, the county town, and the municipal boroughs of Bridgnorth, Ludlow, Oswestry, and Wenlock. It returns four members for the Oswestry, Newport, Wellington, and Ludlow divisions. Clive was a native; and historic scenes or antiquities, other than those noticed in the articles on the different towns, are Acton-Burnell, Boscobel, Wroxeter, Watling Street, and Offa's Dyke. Pop. (1801) 169,248; (1841) 225,820; (1871) 248,111; (1891) 236,324.

See works by C. Hulbert (2 vols. 1837), E. Lloyd (1844), R. W. Eyton (12 vols. 1853-60), J. C. Anderson (1864), Mrs F. C. Acton (1868), M. E. C. Walcott (1879), Miss G. Jackson (Dialect, 1879-81), and Miss C. Burne (Folklore, 1883-85).

Shrovetide, 'shriving-time,' 'absolution-time,' the name given to the days immediately preceding Ash-Wednesday, which, as indeed the whole period after Septuagesima Sunday appears to have been, were anciently days of preparation for the penitential time of Lent. In the modern discipline of the Roman Catholic Church a trace of this is still preserved, as in many countries the time of the confession, which precedes the paschal or Easter communion, commences from Shrovetide. These days were sometimes called Fasting-tide, Fastmass, Fasten-e'en, or Fastern's-e'en, names still retained in some parts of Great Britain, as *Fastnacht* is the regular German name. The name of Shrovetide was retained in England after the Reformation, although the practice of shriving was abandoned. The duty of confession having been fulfilled, the faithful, upon the eve of entering upon the Lent, were indulged with permission to give themselves up to amusements and to festive celebrations, of which the counterpart is still seen in the continental carnival. In England the pastimes of football, cock-fighting and throwing at cocks, bull-baiting, &c. were long recognised usages of Shrovetide; and the festive banquets of the day are still represented by the pancakes and fritters from which Pancake Tuesday took its name, and by the 'collops' which gave its title to Collop Monday. Shrovetide cakes and ale, the last surviving relic of Shrove Tuesday celebrations, were discontinued by Brasenose College in 1887. The *Mardi Gras* of the French, with its merry-makings, is Shrove Tuesday. It is a popular festival at New Orleans.

Shrub. See RUM. For Shrubs, see TREES.

Shumla, or SCHUMNA, a city of Bulgaria, by rail 56 miles W. by N. of Varna and 80 SE. of Rustchuk. The roads from the fortresses (Silistria, Rustchuk) on the Lower Danube and in the Dobrudscha on the north, and from the passes of the Eastern Balkan on the south, converge upon Shumla, and make it an important strategic place. It is defended by strong detached forts and a fortified camp, all of which were to have been demolished according to the Berlin treaty, though the clause stipulating this has not been carried out. Shumla is a straggling place, and has numerous mosques and churches, the splendid mausoleum of Hassan Pasha (18th century), an arsenal, numerous barracks, and a military hospital. It manufactures slippers, clothing, copper wares, and silks. Pop. (1888) 23,161. The fortified works were attacked in vain by the Russians in 1774, in 1810, and in 1828, but were abandoned to them in 1878.

Shusha, a town of Russian Transcaucasia, 65 miles SSW. of Elizabethpol, occupies a strong position on a mountain, which is accessible only on one side, and is moreover defended by a citadel. Pop. (1886) 26,806, who make celebrated carpets and coarse silk goods, and trade in horses that are held in great repute.

Shuster, a decayed city of Persia, stands on the Karun, at the point where that river emerges from the hills, 250 miles W. by S. of Ispahan. It is protected by a citadel. It has been identified by some with the ancient city of Susa, but the site of that city is Sus, 40 miles WNW. of Shuster. Pop. 6000.

Shute, JOHN. See BARRINGTON.

Shwan-pan, the Chinese Abacus (q.v.).

Siah-posh ('black-clothed'), a name given by their Moslem neighbours to the pagan Kafirs of Kafiristan (q.v.).

Sialagogues are substances which increase the secretion of saliva. They may do so by stimulating the secretory nerves of the salivary glands reflexly through the sensory nerves of the mouth, stomach, eye, or nose. Thus, sweet or slightly irritating substances in the mouth provoke a secretion of saliva, while the sight or smell of savoury eatables 'makes the teeth water.' These are known as topical sialagogues, and include such substances as mustard, ginger, pellitory-root, dilute acids, &c. Dilute acids and pellitory-root are the only ones which are much used in medicine to increase the flow of saliva and keep the mouth moist; a small piece of the latter is chewed from time to time. Sialagogues also act after absorption into the blood by a direct stimulating action on the secretory nerves. Jaborandi and mercurial compounds are well-known examples of this class. The former, or its alkaloid, pilocarpine, may cause the secretion of a pint or more of saliva within a short time after administration. This class is known as remote or general sialagogues.

Sialkot, a town in the Punjab, near the left bank of the Chenab, 72 miles N. by E. of Lahore, is a rapidly growing, clean, and well-built town, with large manufactures of paper and a native cloth. There are an old fort, gallantly held by a few Europeans in 1857, but now converted into public offices, several shrines sacred to the Sikhs and the Mohammedans, the Punjab military prison, a public garden, &c. Pop. (1881) 45,760; (1891) 54,930, including the cantonment, one mile to the north.—The *district* has an area of 1958 sq. m. and a pop. (1881) of 1,012,148.

Siam (native name, *Muang Thai*, 'the Land of the Free') occupies the central portion of the Indo-China Peninsula. Its extreme length stretches from 4° in the Malay Peninsula to Chiengsen (20° 22′ N.), on the river Mekhong, or a distance of nearly 1100 miles, and the greatest breadth from E. long. 98° to 109°, or about 750 miles. It is bounded on the south by French Cambodia, the Gulf of Siam, and the British Malay states, and on the west by Burma. The northern frontier was laid down by the Anglo-Siamese Boundary Commission (1890-91), while that on the east, between Siam and Tonquin, was at the same time surveyed by a French party. The range of hills running parallel to the sea-coast of Annam forms the remaining portion of the eastern boundary, but Siam has only a weak hold on the extensive tracts of country between the river Mekhong and those hills, and indications are not wanting to show that France would desire her Indo-Chinese possessions to extend to the east bank of the Mekhong. See map in Vol. II. p. 562.

The area of the country may be estimated at 300,000 sq. m., of which 60,000 are in the Malay Peninsula. The population, which is concentrated principally in Bangkok and the Menam Valley, numbers from 8,000,000 to 10,000,000, of whom possibly 1,000,000 are Chinese.

Physical Features.—The Malay Peninsula excluded, the plain of the Menam Valley, the adjoining eastern coast, and the Korat plateau (from 400 to 1000 feet high) occupy the greater portion of the country. These plains are fringed by hills up to 5000 feet high, and the north generally is hilly. The Menam, with a course of about 600 miles, is the principal river. It is formed by the junction of the Meping and Meyome, and at a point 130 miles from the sea it divides itself and falls into the Gulf of Siam by two mouths, the westerly of which is named the Tachin River. Two other streams, the Meklong and the Bangpakong, flow into the Gulf of Siam. The Mekhong (q.v.) or Cambodia River has the main part of its course in Siamese territory, but navigation for vessels of any size is impeded by rapids, and, commercially speaking, this magnificent river is of little importance at present. The rivers form the principal trade-routes, and in and around Bangkok there is an intricate network of canals. Only the land adjoining the rivers is under cultivation, and the greater portion of the country is covered by pathless jungle.

The climate is considered healthy for the tropics. Low malarial fever is the most frequent illness amongst the European community. There are two seasons—the wet and the dry, the former lasting from May till November, and the latter the rest of the year. The average rainfall is 54 inches per annum, which is slight compared with that of the adjoining countries of Burma and Cochin-China. April is the hottest month of the year, but even then the thermometer rarely rises above 94° in a well-constructed house, and as a rule there are cool breezes at night. The average temperature for the year is 81°.

Productions, Commerce, Exports, and Imports.—The chief production of Siam is rice. It is the national food, and its export forms the great source of wealth of the country. The system of agriculture is of the most primitive kind, but a genial sun, refreshing rains, and alluvial soil combine to produce abundant crops. In 1890, 479,660 tons of rice, valued at £2,508,816, were exported, chiefly to Singapore and Hong-kong for transhipment. This item formed more than two-thirds of the total exports, which amounted to £3,209,621. The other principal exports were teak-wood, obtained in the north, to the value of £200,178, pepper, salt, and dried fish, cattle (for consumption in Singapore), and til (sesame) seed. Goods were imported to the value of £2,631,020. The most valuable items were treasure and gold-leaf, £995,003; cotton manufactures and China goods, £403,184; jewellery, £131,400; opium, £118,292. The principal commerce of the capital is in the hands of Chinese, who own 17 out of a total of 23 steam rice-mills. The labour market is supplied by Chinese coolies, and the best tradespeople and artisans are Chinese. The native Siamese are handicapped to some extent by the requirements of *corvée*, or state labour, but besides they are deficient in that enterprise and energy which are indispensable to successful trading. They confine themselves to agriculture, fishing, boating, and petty hawking, and many are simply idle hangers-on of the nobility. In addition to the exports above mentioned, the country produces hemp, tobacco, cotton, coffee, cardamoms, and many other articles of tropical growth, which are cultivated for local consumption only. Tropical fruits are abundant, the most highly prized being the durian, mangosteen, and mango. The banana is cheap and plentiful.

Animals.—The wild elephant, tiger, bear (in the north), wild pig, deer, monkey, and squirrel abound in the distant jungles. Tame elephants are employed for travelling and for labour, especially in the teak forests in the north. Several specimens of the famous 'white elephant' are kept in the courtyard of the royal palace at Bangkok; but they are not, as is popularly supposed, fed from golden dishes, nor are they regarded with any special veneration (see Vol. IV. p. 290). Crocodiles are found at the mouths of the rivers. The python, cobra, reptiles of various kinds, mosquitoes, ants, fireflies, and tropical insects are plentiful. There are many species of birds, and the rivers and coast swarm with excellent fish.

Minerals.—Gold has been produced in Siam from time immemorial; and argentiferous copper also is found. Alluvial tin-mines are worked by Chinese in the Malay Peninsula, and iron is turned out in the north by native smelters. Rubies and sapphires are found in the Chantaboon district on the east coast of the Gulf of Siam, and the work of mining for these gems is carried on by Burmese immigrants. The country has lately been a field for the researches of mining prospectors, and several concessions, mostly for gold and gems, have been granted to European speculators.

Manufactures.—The Siamese are very deficient in manufacturing arts. The only manufactures are a species of coarse cloth and silk, rough paper made from the bark of a tree, water-jars, and coloured tiles for the roofs of temples. These industries, paltry as they are, are gradually giving way to the import of foreign goods. Native gold- and silversmiths display considerable ingenuity in their work.

Inhabitants and Customs.—Pure Siamese are estimated to number only a third of the total population. The north and east are occupied by Laos or Shans (q.v.), who are tattooed, and differ somewhat in speech from the Siamese, and besides the Chinese there are considerable numbers of immigrant Burmese, Indians, Malays, and Cambodians. The character of the Siamese is essentially peaceful and indolent. They are very social, vain, and fond of bright dresses and jewellery. Their intercourse with each other is conducted with a ceremonious attention to distinction of rank. They are a small, well-proportioned race, with olive-coloured skin, black hair, slight black moustache, and no beard. They shave the heads of their children, with the exception of a tuft on the crown, which is cut off with great ceremony at the age of puberty. The hair is then allowed to grow in the usual fashion, both sexes being alike closely cropped. The national dress both for men and women consists of a bright-coloured panung—a cotton or silk cloth arranged somewhat in the form of Turkish trousers, and reaching to the knee. Princes and well-to-do people wear in addition a white jacket, often with gold or silver buttons, shoes, and white stockings, while the women are distinguished by a gaudy scarf thrown across the bosom.

The houses are built of wood or bamboo, thatched with the leaf of the attap palm, and are raised a few feet from the ground on piles. Both sides of the river at Bangkok (*q.v.*) are lined for several miles with houses floating on wooden pontoons or on bundles of bamboo. Furniture there is none, unless a mosquito-net, a mat or two, and cooking and betel utensils be reckoned furniture.

The food of the mass of the people consists simply of rice, curry stuff, a little dried fish, and fruit. Large quantities of tea are consumed in Chinese fashion without sugar or milk. A spirituous liquor is distilled from rice, but drunkenness is rare. Betel-nut chewing and tobacco-smoking are universal. Children begin to smoke at a very early age, and ladies do not disdain the use of the fragrant weed. Betel-nut discolours the teeth, and this process is often aided by the use of various materials to render them quite black and polished. The characteristic vice of the Siamese is gambling, which can only be carried on in the licensed government gambling houses. At the new-year holidays (in April), and on two or three other public holidays, the people are allowed as a privilege to gamble at home or in the streets.

Marriages are negotiated by elderly women, who find out if the birthdays of the intended bride and bridegroom are suitable—for the Siamese are superstitious in this respect—and arrange the amount of property or money the parents on each side are willing to give to set up the young couple in life. The marriage ceremonies, during which the chewing of betel-nut plays an important part, last two or three days, and all friends are entertained liberally during this time. Priests are sometimes engaged to recite prayers, the bride and bridegroom are sprinkled with consecrated water, and on a favourable astrological day—generally the third—the marriage-bed is prepared by an old couple, friends of the family who have in their time been blessed with a large and prosperous family. Among the poorer classes there is little ceremony. The main feature of the contract is that the swain hands over to his mother-in-law a certain sum of money, which is termed 'ka nam nom,' or price of the mother's milk. Polygamy is universal amongst the wealthy and noble classes.

The system of medicine is curious. The Siamese believe that the arteries are filled with air, and that most diseases are caused by some disturbance in this internal wind. Apoplexy, for example, results from wind blowing upon the heart with sufficient force to rupture it. The vegetable, mineral, and animal kingdoms are largely drawn upon to supply medicines, and the use of such peculiar articles of pharmacy as cat's eyes, bile of snakes, rhinoceros horn, sea-shells, &c. is not despised. Patients are accustomed to take medicines compounded of numerous ingredients and in enormous quantities. It is a painful custom of obstetrics that after the birth of a child the mother lies thirty days roasting before a hot fire. The number of days is diminished with the number of children. The mode of paying doctors might be adopted with advantage elsewhere. A fixed sum is agreed upon for a cure, and if the condition of the patient does not improve, or if he dies, the doctor gets nothing. The dead, after being kept for a period varying from two or three days for a poor man to eight or nine months for a prince, are cremated with much ceremony and at great expense.

Every Siamese, with certain exceptions, is bound to give the state free labour for about three months in the year, and to supply travelling officials with provisions and means of transport when called upon. A form of domestic slavery exists, by which any one borrowing money may offer his person as security. The creditor can put his debtor in chains, if necessary, and compel him to work in his service till the principal is paid off, the value of his labour being reckoned only as interest.

The religion of the country is Buddhism. The sacred books are written in Pali in the Cambodian character, and have been originally brought from Ceylon. All Siamese enter the priesthood for a short time. Priests are clothed in yellow robes, and their heads and eyebrows are shaved. They collect their food from the charitable in the early morning. The temples are numerous, and they are the only buildings, except the palace, on which any architectural effort has been expended. Their gilded minarets, roofs of coloured tiles, and quaint pagodas draw forth the admiration of the stranger on his arrival at Bangkok.

Government and General Progress.—The old system of first and second kings has been abolished, and the present and only king is Chulalongkorn I. (Phra Paramindr Maha), who was born September 21, 1853, and succeeded to the throne October 1, 1868. He is an amiable but dignified monarch, knows the English language thoroughly, and is possessed by a sincere desire to ameliorate the condition of his country. The eldest son of the queen was nominated crown-prince in 1887, and this innovation will tend to make the throne hereditary, which was not formerly the case. The legislative power is vested in the king in conjunction with a council of ministers, who have charge of the departments of war and marine, foreign affairs, home government, justice, agriculture, royal house, and finance. Public money is apportioned between these departments, but there is no published budget. There is a council of state which includes the ministers, ten to twenty members appointed by the king, and six princes of the royal house. The country is divided into forty-one provinces administered by governors. Some of the outlying states are ruled by their own chiefs, but the tendency at present is to replace these by commissioners from Bangkok, and thus to strengthen and centralise the government. The ablest of the king's brothers (two full and twenty half brothers) are selected to fill the more important public offices. Administration of justice is in a very defective state, and property is rendered very unsafe from the thieving and pilfering which is carried on practically unchecked outside of Bangkok. There is a small permanent army to which considerable attention is devoted. It is modelled after the fashion of the British army, and is drilled by Europeans. The navy consists of a few tiny gunboats, nearly all in a decaying condition.

The revenue of the country is estimated at £2,000,000, and includes £1,000,000 for opium, spirit, gambling, pawnbroking, and other farms; £700,000 for taxes on houses, shops, boats, fisheries, theatres, &c.; £200,000 for land-tax; and £100,000 for customs.

The government have within recent years been taking steps to introduce Western improvements. A few roads have been constructed at the capital, and telegraph lines connect Bangkok with Europe *viâ* Saigon, and also *viâ* Tavoy in Burma, and with Chiengmai in the north. The postal union was joined in 1885, and a telephone exchange exists in Bangkok. An electric-light company has been started to light up the city streets. Education, which is carried on by the priests in the temples, has been supplemented by the establishment of schools for the teaching of English. A tramway company, with a line of 6 miles, flourishes in the capital. In 1891 the king cut the first sod of a railway intended to connect Bangkok with the mouth of the river; moreover, there seems some prospect that a line to Korat, 165 miles NE. of Bangkok, will be constructed; and other railway lines are also proposed. Over eighty Europeans are employed in the government service, of whom about half are British subjects. Extra-territorial jurisdiction exists in Siam—i.e. foreigners are not subject to Siamese laws, but to the laws of their respective countries administered by consuls.

History.—Authentic Siamese history does not begin till the year 1350, when Ayuthia (q.v.) was founded. Cambodia was conquered and made tributary in 1532. The period from 1659 to 1688 was rendered illustrious by the career of Constance Falcon (or Phaulkon), a Greek of Cephalonia, who attained the dignity of prime-minister. He was the king's favourite, and induced that monarch to send an embassy to Louis XIV. Ayuthia remained the capital till 1768, when after a siege of two years it was taken and burned by the Burmese. The invaders were finally driven from the country by a general named Phya Tak, son of a Chinaman by a Siamese mother, who made Bangkok the capital, and afterwards ascended the throne. The present dynasty was founded in 1782.

Language and Literature.—The alphabet consists of forty-four characters and twenty vowel-signs. The language is monosyllabic (the polysyllabic words being borrowed from Pali) and has five tones, which render its acquisition difficult to Europeans. The style in which inferiors address superiors differs considerably from the common language, and the sacred books are written in Pali. Literature is comprised in some volumes of history, medicine, laws, astrology, &c., but it is of no particular value. The Siamese are fond of reading fables, romances, plays, &c., of which there is a cheap and abundant supply.

The principal books on Siam are La Loubère, *Description du Royaume de Siam* (1691); Pallegoix, *Description du Royaume de Siam* (1854); Bowring, *Kingdom and People of Siam* (1857); Mouhot, *Travels in Siam, Cambodia, and Laos* (1864); Bastian, *Die Volker des östlichen Asiens* (1866); Leonowens, *The English Governess at the Siamese Court* (1870); Bock, *Temples and Elephants* (1884); Colquhoun, *Amongst the Shans* (1885); Coit, *Siam, or the Heart of Farther India* (New York, 1886); Chevillard, *Siam et les Siamois* (1889); Hallett, *A Thousand Miles on an Elephant* (1889); J. Anderson, *English Intercourse with Siam in the Seventeenth Century* (1890). See also Consular Reports on Siam, several of which contain much general and special information.

Siam, GULF OF, an arm of the China Sea, is bounded on the N. and W. by Siam, and on the E. by Cambodia and Cochin-China. At its entrance, between Cambodia Point and the peninsula of Patani on the Malay Peninsula, it is 245 miles wide, and from the line drawn between these two points it extends 390 miles inland in a north-west direction to the mouth of the Meinam.

Siamese Twins, a name given to two children, Eng and Chang, born of Chinese parents in Siam, in 1811, having their bodies united by a band of flesh, stretching from the end of one breast-bone to the same place in the opposite twin. A union of the bodies of twins by various parts is not an unusual occurrence (see MONSTROSITY). The Siamese twins, purchased of their mother at Meklong, were brought to America by Mr Hunter in 1829, and to England afterwards. After realising a competence by the exhibition of themselves in the various countries of Europe, the Siamese twins settled in one of the southern states of America, where they were married to two sisters, and had offspring. Ruined by the civil war in America, the Siamese twins again made the tour of Europe, and exhibited themselves in London again in 1869. They died 17th January 1874, the one surviving the other two hours and a half only, and then dying from the effect of the shock on a heart already weak.

Sibbald, SIR ROBERT, Scottish naturalist and antiquary, was born of Fifeshire ancestry at Edinburgh, 15th April 1641. Educated at Edinburgh, Leyden, and Paris, he settled in 1662 as a physician in Edinburgh, devoted much time to botany and zoology, and aided Sir Andrew Balfour in establishing a botanic garden. He was knighted in 1682 and appointed Geographer-royal for Scotland, in 1686 was for a short time a convert to Roman Catholicism, and died about 1712. He published many pamphlets on medical subjects, natural history, Scottish history, and antiquities.

His writings include *Scotia Illustrata, sive Prodromus Historiæ Naturalis* (1684); *Collection of Several Treatises in Folio Concerning Scotland, as it was of Old, and also in Later Times* (1707); *A History of Fife and Kinross* (1710); and his *Autobiography* (1833).

Sibbes, RICHARD, Puritan divine, was born the son of an honest wheelwright at Tostock (not Sudbury), Suffolk, in 1577. He was put to Bury school, and afterwards, by the exertions of some friends who saw his promise, was sent to St John's College, Cambridge, as sub-sizar. He graduated B.A. in 1599, was elected Fellow two years after, and was Trinity Lecturer from 1610 till 1615, when he was deprived, as also of his fellowship. But he was at once appointed preacher of Gray's Inn, where he laboured till 1626, when, after declining Usher's offer of the provostship of Trinity College, Dublin, he was made Master of Catharine Hall, Cambridge. He was under the suspicion of Laud, but contrived to escape the penalties inflicted by his courts, and in 1633 was appointed by the king Vicar of Trinity Church. He died 5th July 1635. Fuller tells us Sibbes was most eminent for that grace which is most worth, yet costs the least to keep it, Christian humility, and further, that as a preacher the truth he pressed most urgently on his hearers was the Incarnation. For his heavenly-mindedness he has been called, and not inappropriately, the English Leighton. Among his many books may be named the *Bruised Reed,* which converted Baxter at fifteen; the *Soul's Conflict,* which Izaak Walton bequeathed to his son, as he did the former to his daughter; *Bowels Opened; The Returning Backslider,* &c. There is a complete edition in Nichol's Puritan Divines, with a Life by the Rev. A. B. Grosart (7 vols. 1862-64).

Siberia (*Sibir*), originally the name of a Tartar fort on the Irtysh, is now applied to an immense territory belonging to Russia in northern Asia, bounded by the Ural Mountains on the W.; the Arctic Ocean on the N.; the seas of Behring, Okhotsk, and Japan in the E.; and the Russian provinces of the Kirghiz Steppes and Turkestan, and the Chinese empire (Mongolia and Manchuria) in the S. Taken within these limits Siberia covers an area of no less than 4,833,500 sq. m.—nearly forty times as great as that of the United Kingdom—and has a population of 4,484,550 inhabitants. Its natural divisions, broadly corresponding to the administrative ones, are: *West Siberia,* including the governments of Tobolsk and Tomsk, as also parts of Perm situated on the eastern slope of the Urals; *East Siberia* (governments of Yeniseisk, Irkutsk, Yakutsk, and Transbaikalia); the peninsula of *Kamchatka;* and the *Amur region,* which includes the governments of Amur, Usuri, the maritime province, and the island of Saghalien (Sakhalin). The group of islands, sometimes from the principal one called Liakhov, have been described at NEW SIBERIA. The areas of the provinces with their populations are given under RUSSIA. Immense parts of this territory are still but very imperfectly mapped, especially in the wildernesses of the north and north-east—a few surveys along the chief rivers and lines of communication being the only sources of information. But the leading features of the network of highlands which covers Siberia can be stated in a few words (see also ASIA, Vol. I. pp. 485-487).

The great plateau of eastern Asia enters Siberia to the east of Lake Baikal, where it attains a height of from 3000 to 4000 feet and a width of nearly 1300 miles, and stretches therefrom, with a gradually decreasing height and width, towards the north-eastern extremity of Asia at the Behring Strait. It is fringed on its north-western border by the Great Altai and Sayan mountains, which separate Siberia from North-west Mongolia, the Barguzin and the South Muya ridges, and a series of yet unexplored and unnamed ridges stretching farther north in the same direction; while along its south-eastern border it has the Stanovoi Mountains, which rise as a high wall on the coast of the Sea of Okhotsk, and are continued farther south by the Great Khingan. The border-ridges of the lofty plateau are the highest in Siberia, and their peaks attain heights of from 7000 to nearly 11,000 feet, but very few of them penetrate into the region of perpetual snow. Mountains remaining snow-clad all the year round and giving origin to glaciers are met with only in the Altai (q.v.), at the Munku Sardyk which rises to a height of 10,700 feet amongst the Sayan Mountains to the south-west of Lake Baikal, and in the highlands of the far north-east. In the remainder of Siberia, owing to the dryness of climate, and also perhaps to a warm current flowing in the upper strata of the atmosphere, the perpetual snow-line stands at a great height not attained by peaks 7000 to 9000 feet high. A broad belt of alpine tracts fringes the plateau along its north-western border, assuming a more and more gloomy aspect in proportion as they advance farther north. The whole of this belt is thickly clothed with forests, the summits only of the higher peaks (4500 to 7000 feet) rising beyond the limits of tree-vegetation. The auriferous regions of the Altai, Upper Yeniseisk, Barguzin, and Olekma are situated in this alpine belt. A belt, nearly 500 miles wide, of high plains 1700 to 2500 feet above the sea-level spreads all along the base of the alpine belt, their outer limit being, roughly speaking, a line running from Tomsk towards the north-east. They are very fertile in the south, but of course become less and less suitable for agriculture as they advance into higher latitudes. The whole of West Siberia, between these high plains and the shores of the Arctic Ocean, is an immense lowland which has barely a few hundred feet of altitude and most of which must have emerged from the sea at a quite recent post-glacial epoch. The southern part of these lowlands—the prairies of Ishim, Upper Tobol, and Baraba—is extremely fertile. The soil is a thick layer of black earth, which also penetrates into the lower valleys of the Altai, and the traveller finds there to his astonishment a territory, nearly as large as Great Britain, entirely covered with a luxurious grass-vegetation, with masses of deciduous forest, which is even now the granary of Siberia, and has grain to spare for export to the mines of the Urals. Nearly one-third of the population of Siberia is gathered on those prairies, attaining a density of 20 and 40 inhabitants to the square mile; and the population is more thoroughly Russian than in many parts of European Russia itself, the indigenous population making but two per cent. of the whole.

Farther north, and especially in the space between the Obi and the Irtysh, the country assumes a quite different character; there begin the *urmans*, or immense marshes which cover nearly 100,000 sq. m., entirely clothed with thickets and meagre forests, and quite impracticable in the summer. Even the bear does not venture to cross the marshes when they are not frozen. Agricultural settlements may be found in this region on the banks only of the rivers, while some 30,000 Ostiaks, Voguls, and Samoyedes find scanty means of existence in hunting and fishing. Farther north still begin the *tundras*, which extend along the Arctic seaboard as far as Kamchatka, and cover an aggregate area of some 450,000 sq. m.—more than twice the area of France. The climate of the tundras is really terrible; the average temperatures of December and January are 15 and 35 degrees below the zero of the Fahrenheit scale; the soil is frozen to a great depth, and only thaws on its surface during the short summer. The trees disappear, only a few species venturing to struggle against the cold by spreading as low bushes or by rising but a couple of inches above the ground. The want of drainage adds to the difficulties which vegetation has to cope with, and only a few flowering plants enliven occasional small patches of better protected and dryer soil. Nevertheless some 50,000 human beings wander over these inhospitable tracts, with reindeers and dogs for dragging the sledges across the wilderness. Of the plateau which fills vast tracts in East Siberia the upper terrace, 3000 to 4000 feet high, is quite unsuitable for agriculture, in consequence of its altitude, cold climate, and want of drainage; in fact, the whole of the Vitim plateau and its continuation towards Kamchatka is quite uninhabited. But its lower terrace, which is 2500 to 3000 feet above the sea and is separated from the upper by the Yablonovoi ridge, offers, especially in Transbaikalia, great facilities for agriculture and cattle-breeding, and is peopled by both Buriats and Russians; while the smaller chains of mountains which intersect it are the seat of rich goldfields, and owing to their richness in copper, iron, and silver will certainly become some day an important centre for mining industry. The Great Khingan, which is continued farther north by the Stanovoi Khrebet and is pierced by the Amur about Kumara, is the south-eastern border-ridge of the great plateau, and it also is fringed on its outer side by an alpine belt of several chains of mountains running parallel to the border of the plateau. Owing to this character, the Stanovoi and the Great Khingan are a most important geographical boundary; properly speaking they separate Siberia from a region which is Manchurian in its physical features. As soon as the traveller has crossed this ridge (which hardly rises as a range of hills above the level of the plateau) and has descended a couple of thousand feet down a very steep slope leading to the basin of the Amur, he sees a complete change of scenery. The oak, the walnut-tree which he has not seen since he left the Urals, the vine, and a variety of bushes and trees belonging to the Manchurian and the Japanese floras suddenly make their appearance. When he has emerged from the alpine belt he finds again the same prairies which he has crossed on the Siberian slope of the plateau, and the climate of these prairies remains as continental and the winters almost as cold as in Siberia proper; but the general character of the flora and fauna is totally changed. In fact it is European no more; the species differ from their European congeners, new genera appear, and even the European species offer notable differences from the types familiar in Europe.

Another belt of high plains, 1500 to 2000 feet high, follows. These prairies, watered by the Zeya and its tributaries, and covered with a very fertile soil and excellent oak forests, are the richest part of the Amur territory, and are being rapidly occupied by immigrants, chiefly sectaries, from Russia, who already number about 60,000, and supply the gold-mines on the slope of the Stanovoi with grain and cattle. The picturesque Little Khingan or Bureya Mountains separate the prairies of the Middle Amur from the lowlands of its lower course. The whole of the latter is only now emerging from the Lacustrine period; immense lakes enclosed within quite flat shores intermingle with swamps; and when the autumn rains, due to the monsoons of the China Sea, swell the waters of the Amur and the Sungari, making of the former a stream several miles wide and covering all its low islands, the whole region becomes an immense swamp. Various small tribes of Manchurian origin (Golds, Mangoons, &c.) lead a half aquatic existence on the banks of the Lower Amur and its tributaries, while the Russian settlements are reduced to a number of villages built on the river for maintaining communication along its banks. It is on the border of this region that the capital of the Amur territory, Khabarovka, stands at the junction of the Amur with the Usuri. The rocky and inhospitable mountains of Sikhota-alin, intersected by equally low and swampy valleys, fill the remaining space towards the sea-coast—the mountains rising over the sea as a stone wall, almost entirely devoid of indentations. From Khabarovka the valley of the Usuri leads southwards to Lake Khangka and to the fertile tracts on the frontier of Corea, which surround the Gulf of Peter the Great. In that gulf Russia has at Vladivostok a splendid harbour, reminding one by its general aspect of the Golden Horn of Constantinople. A railway, intended to connect Khabarovka with Vladivostok, was begun in 1891 at its southern terminus, and was strenuously carried on notwithstanding the very great difficulties presented by natural obstacles and the scarcity of population. The island of Saghalien and Kamchatka are separately treated.

Rivers.—The rivers of Siberia are of an immense importance for the life of the country. They all take their origin on the plateau, and, after having pierced the surrounding mountains, enter the plains, where they describe great curves and receive numbers of large tributaries before entering the sea. All of them have moreover this feature in common, that each of them is formed by the junction of a pair of great rivers: such are the Obi and the Irtysh, the Yenisei and the Tunguska, the Lena and the Vitim, the Shilka and the Argun which form the Amur. The three former enter the Arctic Ocean, and repeated efforts have been made of late by both Swedish and English explorers and traders to establish a regular communication between Europe and the mouths of the Siberian rivers, *viâ* the Kara Sea, which is now known to be free from ice for a few weeks every year. These efforts have not been lost, as a couple of steamers now reach every year the mouths of either the Obi or the Yenisei, with a cargo of machinery and various manufactured goods. Owing to the great depth of the Siberian rivers, Nordenskiöld was enabled to sail up the Yenisei as far south as 60° N. latitude, while a schooner which was built at Tiumen, on a tributary of the Obi system, could sail to London with a cargo of Siberian wheat. But for the interior communication the rivers are of still greater importance. A line of railway crossing the Urals now connects the Kama, a great tributary of the Volga, with the town Tiumen, and steamers ply regularly from Tiumen to Tomsk, the capital of West Siberia; to Barnaul and Biysk in the Altai Mountains; and to Semipalatinsk in the Kirghiz Steppes. Besides, a canal has recently been dug to connect the Obi with the Yenisei, and, when it has been deepened and some rapids on the Angara have been cleared, goods will be transported from the Urals to Irkutsk, the capital of East Siberia, situated within 40 miles of Lake Baikal. No less than 164 steamers (4000 horse-power) already ply on the Obi and the Irtysh. The Yenisei is also navigated as far as Minusinsk, a small town situated within 300 miles of the Mongolian frontier, in a very fertile region which is often described as the Italy of Siberia on account of its rich vegetation. The Lena is navigated by steamers from Verkholensk (200 miles N. of Irkutsk) to its mouth—large quantities of corn and various goods being shipped to the gold-mines of the Olekma; smaller steamers also navigate the Vitim. On the Amur forty-five steamers (2800 horse-power) ply for a distance of 2000 miles, from Sryetensk in Transbaikalia to its mouth; while its tributary, the Usuri, permits steamers to approach within 100 miles of Vladivostok.

Overland communication is maintained by means of post-stations between all the chief towns—the great highway from Russia to the Pacific passing through Tiumen, Omsk, Tomsk, Krasnoyarsk, Irkutsk, Tchita, Blagoveschensk, and Khabarovka, the capitals of all the southern provinces. Communication remains, however, difficult along the Shilka and the Amur, where long distances have to be traversed on horseback, especially when ice is drifting on the river before it is frozen, or when it is about to thaw. Two lines of railway already enter Siberia from the west—the line Perm to Tiumen, not yet connected with the other Russian railways, and the line Ufa to Tchelabinsk, which joins at Samara the railway-net of European Russia. The new railway which it is proposed to build across Siberia will follow the above-mentioned highway, and probably will be built in parts, beginning with the spaces which have no water-communication. Its total length, from the Urals to Vladivostok, must fall little short of 5000 miles, and its cost is estimated at 340 million roubles (£3,400,000).

Lakes.—Numberless lakes dot the surface of both plateau and lowlands. The chief of them is Lake Baikal (q.v.); Tchany in the prairies of Tomsk (1300 sq. m., but rapidly desiccating); Gusinoye in Transbaikalia; and Khangka (1690 sq. m.), connected with the Usuri.

Climate.—Siberia fully deserves its reputation of being the coldest country of the world. However, with the exception of the Pacific seaboard, it has a much warmer summer than it is generally supposed to have. In the interior of the country one must go as far north as the 60th degree of latitude to find in July an average temperature of less than 60°; while in moderate latitudes July has an average temperature of from 61° to 67°, and 69° on the Middle Amur. The hot summer and a cloudless, bright sky favour vegetation, and one learns to his astonishment that melons are grown in the open air in the steppes of Minusinsk and Irkutsk, or that barley which has been sown in May about Yakutsk (62° 2′ N. lat.) ripens by the end of August. But the summer is short, as a rule, and cold weather sets in very rapidly. Night frosts are usual in September, and in November all rivers are frozen; even the Baikal becomes a highway for sledges in January. In November, even in South Siberia, the mercury of the thermometer is occasionally frozen, and in December and January it remains frozen for weeks. The spring begins in April or May, according to the latitude, and is very pleasant, though it still freezes hard at night; but in the second half of May, when all fruit-trees are in full blossom, there is a sudden return of cold which prevents apples and pears from being grown in Siberia. In the far north the cold is really terrible, and Verkhoyansk, although its latitude is only 67° 34′ N., is the cold pole of the eastern part of the northern hemisphere. Temperatures as low as – 75° and – 85° F. have been measured at Verkhoyansk and Yakutsk. Man certainly could not stand such low temperatures, were it not for the dryness of the atmosphere and the absence of wind during the great frosts, which render them more supportable than might be supposed. Not so with the snowstorms, which are frequent by the end of the winter, and are most dangerous to both man and cattle.

Population.—The population of Siberia is very unequally distributed over the territory. As already mentioned, there are from 20 to 40 inhabitants to the square mile in parts of South Tomsk and Tobolsk, while the deserts of the far north are almost uninhabited. The total population of Siberia, which was less than 1 million at the beginning of the 19th century, has now attained 4,598,500, and it is yearly increased by some 50,000 new immigrants coming from Russia; so that in western Siberia a want of free land available for agriculture is already felt by the new-comers. The Russians in Siberia proper already number more than 3,800,000. They occupy the best parts of the territory in the south, as well as the valleys of the chief rivers. The indigenous population, barbarously exterminated by the Turkish and Mongolian conquerors of the country in the 12th and 13th centuries, and by the Russian conquerors in the 17th and 18th centuries, hardly numbers now 700,000; whole tribes have almost entirely disappeared. The natives belong to various stocks: the Ugrian stock is represented by the Voguls, the Ostiaks, and the Samoyedes on the slopes of the Urals. Various small stems of Turkish origin inhabit the slopes of the Altai and Sayan mountains; they number about 80,000; while the Yakuts, belonging to the same stock, number no less than 200,000. The Mongolian race is represented by the Kalmucks (about 20,000 in the Altai), the Buriats (250,000) around Lake Baikal, and the Tunguses (about 50,000), who lead a nomad existence in the mountains of East Siberia and the Amur region. Nearly 15,000 Manchurians and Chinese continue to stay on Russian territory of the Amur and Usuri; and more than 3000 Coreans are settled around the Gulf of Peter the Great. Finally, in the north-east there are several stems usually described as Hyperboreans and akin to the Eskimos: the Tchuktchis (12,000), the Koryaks (5000), and the Kamchadales (3000). On the Lower Amur we find the Ghilyaks (about 5000), and in the island of Saghalien the Ainos (3000). The condition of the aborigines is altogether precarious; their hunting and grazing grounds are constantly invaded by Russian settlers, and they themselves become an easy prey to the traders, who enslave them by means of loans of food, gunpowder, &c. The numbers of most of them, save the Yakuts and the Buriats, are declining, and some stems will soon totally disappear—a fact which is much to be regretted, because their children, when they have received education in Russian schools, generally prove to be useful workers in various branches of science and art. As to the Russians in Siberia, the old stock of early settlers, chiefly of North Russian origin, differ a good deal from the bulk of the Great Russians. Not having known serfdom (only 8000 peasants in West Siberia and 20,000 peasants who belonged to the emperor's mines in East Siberia were serfs in 1861), they are of a more independent spirit; but these descendants of the Novgorodian traders also are much more individualistic and almost devoid of poetical gifts, though very successful as a rule in exact sciences. The chemist Mendeleyeff, the historian Schapoff, the zoologist Polyakoff, and several other men of mark are of Siberian extraction. On the outskirts of the continent the Russians, especially during the first centuries of the conquest, underwent a good deal of mixture with the aborigines—Samoyedes, Ostiaks, Buriats, and Yakuts.

A great variety of religions are met with in Siberia. The Russians belong chiefly to the Greek Orthodox faith, or rather to some of the nonconformist sects, the very making of Siberia being due to the emigration of dissenters persecuted by government in their mother-country, as well as to the runaway serfs, and at a later epoch, to the desire of avoiding military service. Most Turkish tribes profess the Mohammedan faith, which is steadily winning new converts. The Buriats profess Buddhism; and most Ugrian and Finnish stems, as well as the Hyperboreans, are Shamanists. Christianity is making but very slow and nominal progress.

Exiles.—The rapid increase of population which has taken place in the last quarter of the 19th century is chiefly due to free immigration. As to the exiles, of whom no less than a million have been transported to Siberia since 1840, and who are transported now to the number of 20,000 every year, they have contributed but little to the increase of the settled population. After having been kept for a number of years in prisons in complete idleness, and spent a couple of years on the journey, large parts of which are still made on foot, they are quite unable to become regular agriculturists. They look upon Russia as their mother-country, and very many of them make an attempt to return to their native villages. They run away, wander on foot through the forests, and, after having been re-arrested and brought back to their settlements, they repeat again and again the attempt on the next opportunity. Others join the ranks of the floating population, and perish in numbers on long pedestrian journeys to and from the gold-mines.

Agriculture, Industry.—Agriculture and cattle-breeding are the chief occupations. The regions of Tomsk, South Tobolsk, Minusinsk, Irkutsk, and Middle Amur produce more corn than is wanted for the population, and export some. It may be taken that the annual production of all sorts of corn (summer wheat, rye, oats, and barley) in an average year amounts to or exceeds 7,000,000 quarters in West Siberia, and 4,500,000 quarters in East Siberia. Cattle-breeding is extensively carried on, especially in the steppes of the east. It is roughly estimated that there are about 2,000,000 horses, 1,500,000 head of horned cattle, 3,000,000 sheep, and 100,000 reindeer in West Siberia, and about 850,000 horses, 1,100,000 horned cattle, 1,120,000 sheep, and 50,000 reindeer in East Siberia. Hunting continues to be profitable in some parts of the territory, notwithstanding the reckless extermination of wild animals and burning of forests which have been going on for three hundred years. Sables, Arctic foxes, and gray foxes become rare; so that squirrels, common foxes, bears, deer, and antelopes, as also some ermines and a few beavers in the north-east, are the chief object of the hunter. Even the sables which were so numerous on the Amur when the Russians first occupied it are rapidly being exterminated. Fishing is extensively carried on on Lake Baikal, the Amur, the Obi, and other rivers. Industry is in its childhood. With the exception of the Tiumen region, where some carpets are woven in the peasants' houses, and a few domestic trades are resorted to in the winter, the Russians in Siberia do not carry on the domestic industries so characteristic of middle Russia. In Transbaikalia the want of the simplest technical knowledge is simply astonishing. Therefore, although Siberia has all the raw produce that may be wanted for the development of a prosperous industrial activity, the want of technical skill prevents the growth of industries. It must also be said that the prospects of a sudden enrichment in the lottery of gold-mining diverts the attention of the population and the few capitalists from the surer industrial pursuits, and that the first steps in that direction are beset with difficulties in a country devoid of railways, domestic industries, and technical schools. Yet the influence of the mining and industrial centres of the Urals is already felt in West Siberia. Tiumen has its establishments in which steamers provided with all modern fittings are built with full success.

Although Siberia is very rich in all kinds of ores, the same causes prevent the development of rational mining, which still remains chiefly limited to gold-washing, very primitive in most cases, and only here and there supplied with modern machinery. The production of gold is considerable. In the period 1860-90 no less than from 404 to 584 cwt. of gold annually were obtained in East Siberia, and 48 cwt. in West Siberia, exclusive of Perm. In 1888 the figures of extraction of gold were: Tomsk, 43 cwt.; Yeniseisk and Irkutsk, 98; Transbaikalia, 56; Yakutsk, 149; Amur, 125. Silver is extracted in the Altai to the amount of from 130 to 300 cwt. every year; lead, 3250 cwt. in the Altai, and 232 cwt. in Nertchinsk; copper, 5800 to 7740 cwt. in Altai; iron, 97,000 to 130,000 cwt., to which the considerable production of the ironworks of the eastern slope of the Urals ought to be added.

Education still stands at a very low level, the total numbers of pupils in schools throughout Siberia hardly exceeding 60,000 boys and girls. A university has been opened at Tomsk (1888), after much opposition on behalf of the government, but it has only two faculties, medical and juridical. In the chief towns of each province there are gymnasia in which some education on classical lines is given, but primary and technical education is in great neglect. The technical society of Irkutsk has, however, made some progress in the latter direction. The geographical societies at Omsk and at Irkutsk are known for their scientific publications. Natural science and anthropological museums have been opened of late by some exiles, and those of Irkutsk, Minusinsk, and Yeniseisk contain valuable collections.

History.—The earliest history of Siberia is still imperfectly known, and the numberless tumuli scattered over its surface only begin to be scientifically explored. The earliest inhabitants seem to have belonged to a stock different from the Ural-Altaians, and are described by Radloff as Yeniseians. They were followed by the Ugro-Samoyedes, whose bronze ornaments buried in the tumuli testify to a high pitch of artistic skill. They were subdued in the 11th century by Turkish invaders, who themselves were conquered, two centuries later, by the Mongols. The latter swept away the previous civilisation. The Russians, who vaguely knew Siberia since the 11th century through the Novgorodian merchants, began the conquest of the territory in 1580, when a band of Cossack robbers under Yermak subdued the Tartars on the Tobol River. New and new bands of Cossacks, traders, and hunters, supported by the Moscow government and followed by dissenters flying from religious persecution and peasants escaping from serfdom, poured into Siberia during the next two centuries. The Cossacks took possession of the country, and reached the coasts of the Sea of Okhotsk within the first eighty years after Yermak's expedition. In 1643-50 they also took possession of the Amur, but were compelled by the Chinese to abandon their settlements and forts (1689). The estuary of the Amur was discovered in 1849, and a military post established at the mouth of the river in 1851. The left bank of the Amur and the right bank of the Usuri were annexed in 1853-57; a chain of villages was built along both rivers, and the 'accomplished fact' was recognised by China in 1857 and 1860. The Behring Strait was discovered in 1648 by the Cossack Dejneff, who sailed that year around the north-eastern extremity of Asia; but the fact remained unknown, and the scientific discovery of the passage between Asia and America belongs to Behring. The first circumnavigation of Asia was, however, not accomplished till 1878-79, when Nordenskiöld, on board the *Vega*, sailed through the Arctic Ocean, wintered on the Siberian coast, entered next spring the Behring Strait, and returned to Sweden *viâ* the Japanese and Chinese Seas, the Indian Ocean, and the Suez Canal.

The *Géographie Universelle* of Élisée Reclus, vol. vi. (English trans. by Professor Keane), is the best source of general information in English. See also Ravenstein's *Russians on the Amur* (1861); Seebohm's *Siberia in Asia* (1882); Lansdell's *Through Siberia* (1882); Kennan's *Tent Life in Siberia* (New York, 1870), and *Siberia and the Exile System* (1891); Radloff's *Aus Sibirien* (1884), and other works; and H. de Windt, *Siberia as It is* (1891). Of the numberless Russian works, see the relevant volume of the work called 'Picturesque Russia,' by various writers, and Yadrintseff on 'Siberia as a Colony' (German trans. 1886).

Sibi, a pass, town, and district, in the occupation of Britain, on the frontier of Afghanistan and Beluchistan. The town, which has a station on the Sind and Pishin Valley Railway, is the residence of the British political agent. The inhabitants of the district, mostly Pathans and Beluchis, number about 14,000.

Sibyl, the name given in antiquity to certain inspired prophetesses, whether Apollo's mistresses or daughters, or merely his priestesses. The name is explained by Lactantius on authority of Varro as made up of the Doric *sios* = *theos* and *bylē* = *boulē*; Maas tries to connect it with the Eastern *Saba* or *Sabæ*; Bang makes bold to connect it with the *Volva* and *Voluspá* of the Old Norse Sagas. Their number is differently given; some writers—Ælian and Pausanias, for example—mention only four, the Erythræan, the Samian, the Egyptian, and the Sardian; Aristophanes and Plato use the word in the singular number only; but in general ten are reckoned, as by Varro—the Babylonian, the Libyan, the Delphian, the Cimmerian, the Erythræan, the Samian, the Cumæan, the Trojan or Hellespontine, the Phrygian, and the Tiburtine. Of these by far the most celebrated is the Cumæan, identified by Aristotle with the Erythræan, and personally known by the names of Herophile, Demo, Phemonoë, Deiphobe, Demophile, and Amalthæa. She figures prominently in the 6th book of Virgil's *Æneid*, as the conductor of the poet into the realm of the shades. Livy records the legend that she came from the east, appeared before King Tarquin, and offered him nine books for sale. The price demanded appeared so exorbitant that the king refused to purchase them. She then went away, destroyed three, and returning, asked as much for the remaining six as for the nine. This was again refused, whereupon she destroyed other three, and once more offered to sell him the remainder, but still at the same price asked at first. Tarquin was struck by her pertinacity, and bought the books, which were found to contain oracular advices regarding the religion and policy of the Romans. They were preserved in a subterranean chamber of the temple of Jupiter on the Capitoline, and were originally entrusted to two officials (*duumviri sacrorum*), appointed by the senate, who alone had the right to inspect them. The number of keepers was afterwards increased to ten (*decemviri*), and finally by Sulla to fifteen (*quindecemviri*). In the year 83 B.C., the temple of Jupiter having been consumed by fire, the original Sibylline books or leaves were destroyed, whereupon a special embassy was despatched by the senate to all the cities of Greece, Italy, and Asia Minor, to collect such as were current in these regions. The new collection, of about a thousand lines, was deposited in the rebuilt temple of Jupiter, but was transferred in 12 B.C. by Augustus as *pontifex* to the temple of Apollo on the Palatine, where it remained till it was publicly burned by Stilicho, between

404 and 408. Many spurious Sibylline prophecies in private hands were taken by Augustus and burned. Quite distinct are the fourteen books of so-called *Sibylline Oracles* in Greek hexameters (over 4000 lines), a series of pretended prophecies written by Alexandrine Jews and Christians, in the interest of their faiths, and supposed to date from the 2d century B.C. down to the 3d century A.D., or, according to Ewald, even the 6th. The origin and signification of many passages have caused fierce discussion, but beyond doubt many are plainly Jewish and pre-Christian, others as plainly Christian. One passage in the eighth book (217–250) touched powerfully the imagination of that Christian world which found no difficulty in reading Messianic prophecy into the vague spirituality of the fourth eclogue of Virgil. This passage, alone in the whole series, is written acrostically, like all the Sibylline verses of Rome, the initials forming the Greek words for Jesus Christ, Son of God, Saviour, Cross. It is alluded to in the *De Civitate* of Augustine, and we find it again in the solemn Sequence of Thomas of Celano: 'Dies iræ, dies illa Solvet sæclum in favilla, Teste David cum Sibylla.' And it was the same sense of mysterious continuity between the ancient order and the new that gave so rich a motive to mediæval art in masterpieces by Giotto, Michelangelo, and Raphael.

Editions of these so-called *Sibyllina* are by Alexandre (Paris, 1841–56), a monument of erudition, the second volume with an exhaustive commentary; Friedlieb (Leip. 1852); A. Rzach (Vienna, 1891); and H. Diels (Berl. 1891). See works devoted to discussion of the question by Ewald (1858), Dechent (*Zeitschr. fur Kirchengesch.*, 1878), Badt (1869 and 1878, the latter an edition of book iv.), Maas (1879), and Bang (trans. by Poestion, 1880); also an admirable article in the *Edin. Review* for July 1877.

Sicilian Vespers, the name given to the massacre of the French in Sicily on Easter Monday (March 30) 1282, the signal for the commencement of which was the first stroke of the vesper-bell. Charles of Anjou, brother of Louis IX. of France, had deprived the Hohenstaufen dynasty of Naples and Sicily; but his cruelty and tyranny, his oppressive taxation, and the brutality of his followers excited among the Sicilians the deadliest animosity. So on that evening the inhabitants of Palermo, enraged (according to the common story) at a gross outrage offered by a French soldier to a young Sicilian bride, suddenly rose against their oppressors, and put to the sword every man, woman, and child to the number of 8000. This example was followed by Messina and the other towns, and the massacre became general throughout the island: the French were hunted like wild beasts, and dragged even from the churches. The 600th anniversary of the Sicilian Vespers was celebrated with much enthusiasm in 1882, Garibaldi (shortly before his death) having come to Palermo on purpose to be present, though he was too feeble to take part in the ceremonies. See Amari, *La Guerra del Vespro Siciliano* (Eng. trans. by Earl of Ellesmere, 1850).

Sicily, the largest, most fertile, and most populous island in the Mediterranean Sea, lies in 36° 38′—38° 18′ N. lat. and 12° 19′—15° 42′ E. long., and is separated from the mainland of Italy by the narrow Strait (*faro*) of Messina (2 miles wide). Its shape roughly resembles a triangle (whence the early Greek navigators gave it the name of *Trinacria*, the 'Three-cornered')—the eastern coast, from Capo di Faro in the north to Capo Passaro in the south, forming the base, and the northern and south-western coasts the sides, which gradually approach each other towards the north-west. Area, 9828 sq. m. (one-third that of Scotland); of the *compartimento* (including adjacent islands), 9936 sq. m. Pop. (1881) 2,927,901; (1890) 3,285,472. Capo Passaro, at the south-eastern extremity, is only 56 miles from Malta; and Capo Boco, near Marsala, at the western, only 80 miles from Cape Bon on the African coast. The Strait of Messina is nearly everywhere over 150 fathoms deep; but its narrowness and the conformity of the geological structure on both shores bear witness that the island was formerly a part of the mainland with which it has always been so closely connected politically. Of fourteen new forts for the protection of Messina and the straits five were finished in 1889.

Sicily is for the most part a plateau from 500 to 1900 feet above the level of the sea, and traversed throughout its northern half by a chain of mountains. The north and east coasts are steep and rocky, the south and west generally flat; the best harbours and the shortest rivers are found in the north. The mountain-chain may be looked upon as a continuation of the Apennines (q.v.). Beginning at Capo di Faro on the Strait of Messina, it runs in a south-south-westerly direction as far as Taormina, where it turns off to the west, and stretches across the whole island. The first part of the chain, from Capo di Faro to Taormina, is called the Peloritan range, which in Monte Dinnamari attains the height of 3700 feet. The second and much the longer part is called the Nebrodian range; near the middle of the north coast it receives the local name of Le Madonie, and rises in the Pizzo d'Antenna to 6467 feet (the highest point in the island except Etna). Immediately to the west of the Madonie there is a notable depression, whose waters are carried off by the rivers Grande and Salso to the north and south coasts respectively; beyond this point the mountains for some distance maintain the character of a chain, but gradually lose this and break up into irregular and often detached masses, ending in the precipitous walls of Monte San Giuliano (ancient *Eryx*, 2464 feet), which rises straight from the sea. About the centre of the chain a range branches off through the heart of the island to the south-east—at first wild and rugged, but afterwards smoothing down into tablelands, which in turn slope away tamely to the sea. There are innumerable other spurs to the south from the great northern chain, which rise in several peaks to over 5000 feet: Monte Cammarata reaches 5177 and Rocca Busambra 5299 feet. Tertiary limestones occupy most of the island; the Nebrodian rocks are mainly of Oligocene date. The lower mountain-slopes are in general covered with groves of oranges and olives, and most of the plateau with fields of wheat. The only extensive plain of special note is that of Catania (given up to vineyards), out of which Etna (q.v.) rises to a height of 10,850 feet, with a base 400 sq. m. in extent. Although rivers are numerous, none are navigable. The principal perennial streams are the Simeto, the Salso, the Platani, and the Belici. The largest lake is the Lagho di Lentini, near the east coast, which has an area of less than 4½ sq. m.

The climate of Sicily is warm and equable, especially on the north and east coasts. The mean temperature in the years 1871–86 ranged from 45° F. in winter to 79° in summer; during the same period the extremes recorded were 25° (Caltanisetta) and 118° (Palermo); but only for brief periods does the dry parching Sirocco (q.v.), chiefly in the spring and early autumn, drive the thermometer up to over 100°. Snow seldom falls in the lowlands; on the Madonie, however, it lies till June, and on Etna till July; and the temperature in winter in the wretched mountain towns is often bitterly cold. The reckless destruction of the forests, for which the whole island anciently was famed, has wrought serious injury to both the climate and the soil. This process is still going on, and little is done in the way of reafforesting; yet magnificent relics of the primeval forests of oak and ilex are left on the Madonie and elsewhere, and in some districts beeches clothe the mountains to their very summits, and chestnuts, pines, and enormous holly-trees flourish; on the other hand, wide tracts have been reduced to absolute sterility by the destruction of the woodlands. Malaria is endemic in many parts—sometimes more so in the uplands than upon the coast. Nearly all the rain falls in the winter months, when the rivers are swollen to destructive torrents; in the long summer there are usually three months of drought, most of the streams dry up, and the hillsides and plains are turned to brown, sunburnt deserts. Nevertheless the soil is naturally so fertile that even these causes and the ignorance and primitive methods of the people have not yet destroyed its marvellous productive power. Vegetation is everywhere luxuriant. Dwarf-palms abound, in the south-west especially, and dates, Indian figs, agaves, prickly pears, oranges, lemons, olives, almonds, pomegranates, mulberries, and grapes are all largely grown. Sicily's wheat still represents a seventh of that of all Italy; and of the kingdom's barley, though the figures are much smaller, it raises one-half. Formerly corn was grown and exported at a profit; but of late years this can no longer be done, and to-day the island's chief agricultural products are grapes, oranges and lemons, and sumach. It sends out two-thirds of Italy's wine, which till the rupture of the commercial treaty with France (see ITALY, Vol. VI. p. 244) was mainly exported thither for mixing purposes; of 'green fruit' it yields nearly nine-tenths of all the Italian crop, and sends large quantities to the United States and to Britain; and sumach, for tanning, is exported to the value of nearly a million sterling. But the Sicilians will change neither the methods nor the implements of their fathers. In many districts the soil is enfeebled by being perpetually cropped with wheat, and only the rich supply of sunshine saves it from exhaustion; artificial manures are unknown, and good systems of irrigation and of rotation of crops are even more needed than the introduction of agricultural machinery. At present ploughs of rough-hewn branches, the wooden share thinly shod with iron, are in use, and the corn is usually threshed on the smoothest spot in or near the field—trampled by oxen and horses, who drag heavy stones after them—and winnowed by being thrown into the air. Cattle-rearing, in the usual sense of that term, is not attempted. Oxen and cows are bred for purposes of labour, not for the market or the dairy, and are sent old from the cart or plough to the butcher. But indeed in the interior little meat is eaten at all. Sicilian mutton is as tough as the beef, and has besides a very rank, woolly flavour. Goats are much more common than sheep, and pigs are reared in great numbers in the mountainous tracts, and in the small towns overrun the streets and act as scavengers. There is no regular pasturage for flocks and herds, which live entirely in the open air, and usually gather a subsistence as they can; when straw and cactus-leaves fail they are in some parts fed on the rinds of oranges and lemons. Butter, mostly imported in tins, is known only in the large towns, and the cheeses of the island, chiefly made from goats' and ewes' milk, are hard and bitter.

After agriculture the production of sulphur is the most important occupation. This is the only mineral product obtained on a large scale, and forms the essential resource of Sicily; but it too is separated from the ore by a very primitive process. There are some 300 mines in the island, and 350,000 tons have been exported in a year; in 1888, however, when the lowest record was touched, the export fell to about half this amount. The rich deposits of rock-salt are scarcely worked at all, though bay-salt is largely made in the salt-pans on the east and west coasts. Fishing, especially for the sardine and tunny, occupies a large number of the people; the coral-fishery has greatly declined. Amber is found and worked in Catania. Manufactures are few and of little consequence—some machinery, cement, crockery, gloves, macaroni, and soap nearly exhaust the list. Commerce is mainly in the hands of English, Germans, and Swiss. Over 30,000 vessels yearly enter the sixty ports, and trade as a whole has developed rapidly since 1860. It is, however, much hampered in the interior by the scarcity of good roads—the whole island in 1889 boasted only 3200 miles; 611 miles of railway were built between 1863 and 1890.

As a consequence of the successive foreign settlements on the island the population is rather a conglomerate one; in the east the Greek element prevails, and the people are superior to those in the west, where Arab blood is strongest. In some places in the interior the dialect of the Lombards survives in their descendants, and near Palermo (Piana dei Greci, &c.) both Greek usages and Greek costumes are to be found. The general dialect of the island differs markedly from that of the mainland, as does also the appearance of the country. Most of the farms are small; but in any case the traveller cannot but be struck with the absence of farm-buildings and houses. The labourers as a rule herd in the small towns, walking wherever possible to their work every morning, and otherwise, in spring and harvest, sleeping during the week in temporary conical huts of straw. The crops are guarded, and the losses of tenants from predatory animals, &c. certified, by mounted guards in the pay and uniform of the chief proprietors. Wages range from 1s. to 2s. per day, without food; the peasant seldom tastes even goat's flesh, and lives on black bread, onions, beans, herbs, prickly pears, bitter cheese, and weak wine; the boy swineherds receive only bread, and find water for themselves. The houses of these labourers consist usually of one room in a town perched on the top of a hill or mountain, shared with such poultry and pigs as they may have; the place is dirty, cold, with a tiled roof through which the smoke escapes and the rain enters, the bed being, when possible, sheltered by a strip of matting. The roadway in front commonly serves for latrine and dressing-room. The houses of the craftsmen are no cleaner, but possess tiled floors and more decent furniture. As for the better classes, they are confined to the cities: there are proprietors in Sicily, but no country gentlemen, nor any houses for them; country life there is absolutely none. Even market-towns are unknown; only sometimes fairs are held in the interior. But in spite of his wretched life, labouring from sunrise to sunset all through the year, and steeped in poverty to the lips, the Sicilian is manly and independent, good-humoured and obliging, prudent and steady in his habits. Under proper direction he will work hard and cheerfully, and his patience and resignation to his lot are truly Oriental: 'come Dio vuole' is but the 'kismet' spirit localised. He is also, however, deceitful, taking pride in his cunning, is heartlessly cruel to animals ('they are not baptised,' he explains), and can be sullen and treacherous and vindictive. In homicides, which occur almost daily, Sicily leads the rest of Italy; and robberies and thefts are very frequent. Brigandage on the grand scale has been put down, but cases of less note do occur still from time to time, and bands of highwaymen occasionally attack even carriages escorted by carabinieri. The Mafia (q.v.) is not dead yet, and the vendetta (worn down by affectionate familiarity to 'vinnitta') is preferred to more legal methods of punishment. This state of things is largely to be traced to the low rate of wages and the excessive taxes, and to the deficient administration of justice; the two former causes certainly are responsible for the emigration of thousands of Sicilians every year to America. In religion the people are devout, and superstitious to a degree. They are very illiterate; three in every four can neither read nor write. Education is free and compulsory, but the law is not very strictly enforced. In 1888 there were 3340 elementary schools in the island, 13 normal schools, 67 'licei,' &c., 46 technical schools, besides government technical institutes, industrial schools, schools of mercantile marine, a military college at Palermo, a government conservatoire at Palermo, schools of agriculture and universities at Catania, Messina, and Palermo. The island is divided into seven provinces (see ITALY), and its chief towns are Palermo (pop. in 1890, 267,416), Messina (142,000), and Catania (109,687).

See Franchetti and Sonnino, *La Sicilia nel 1876* (Flor. 1877); German works by Hoffweiler (Leip. 1870), Th. Fischer (1877), Von Adrian (Berl. 1878), Von Lasaulx (Bonn, 1879), Gregorovius (6th ed. Leip. 1888), Schneegans (1886), and Gsell Fels (1889); Mrs F. Elliott, *Diary of an Idle Woman in Sicily* (1881); the *Annuario Statistico Italiano* for 1889-90 (Rome, 1891); and the valuable Reports by Consul Stigand, especially that for 1889 (F.O. ser. No. 813, 1891).

History.—The earliest inhabitants of Sicily of whom we know anything were the Sicani, who may have been an aboriginal pre-Aryan people like the Ligurians, Iberians, or the still surviving Basques. Somewhere about the 11th century B.C. the Siculi, most probably an Aryan race, were believed to have crossed the strait from Italy; and we hear of yet another early stock mainly in the north-eastern corner, the Elymoi, whose towns of Segesta and Eryx showed a considerable progress in civilisation. The Phœnicians from an early period began to make settlements—Motya and Panormus—mostly on the north and north-west coasts, for the purposes of commerce; but the real civilisers of Sicily were the colonies of immigrant Greeks, both Dorian and Ionian, who founded a number of flourishing cities on the east and south coasts, such as Naxos (735 B.C.), Syracuse (734), Leontini and Catana (730), Megara Hyblæa (726), Gela (690), Himera (648), Zancle or Messana (date uncertain), Selinus (*c.* 628), Agrigentum (579). These Greek settlers became known as Sikeliots, in distinction to the native Siculi, with whom, however, they gradually became assimilated. Their cities were long independent, and flourished first under oligarchical constitutions, then under the short-lived rule of a succession of more or less enlightened *tyrants* like Phalaris and Theron of Agrigentum, and Gelon, who in 485 transferred the seat of his power from Gela to Syracuse, thereafter the first city of the island. The inevitable struggle with Carthage soon began, and its first stage was closed for seventy years by the great victory of Himera (480), won over Hamilcar on the same day as Salamis, by the united power of Gelon and Theron. The long Peloponnesian war and the intrigues of the mother-cities in Greece drew Sicily into the current of Greek history, but the fatal Athenian expedition to Syracuse (415-413) under Nicias (q.v.) ended for ever the Athenian dream of a wider empire in the west. Next followed a Phœnician invasion under Hannibal, grandson of the Hamilcar who perished at Himera. His course of conquest was facilitated by internal jealousies, and he took in turn Selinus, Himera, and Agrigentum, leaving behind him nothing but smoking ruins. Their strong fortress of Lilybæum was founded about 397. But the vigorous reign of Dionysius the Tyrant at Syracuse (405-367) put a check to Carthaginian conquest. He fought Carthage in four wars, and carried his conquests into Southern Italy. After the tyranny of Dionysius and his son followed Dion and Timoleon, next the splendid but fatal reign of Agathocles (317-289). The Sicilian war of Pyrrhus of Epirus (278-276) was but the prelude to the long struggle between Rome and Carthage, the first stage of which was the war for Sicily. First Carthaginian Sicily in 240, then the whole island in 210 passed into a Roman *province*, on the death of Hieron, for fifty years a steadfast ally of Rome. The chief events in Sicily's Roman history were the two insurrections of slaves (135-132 and 102-99), the infamous pro-prætorship of Verres (73-71), its occupation by Sextus Pompeius (42), the conquest by the Vandal Genseric (440 A.D.), his cession of the island to Theodoric, and its recovery to the eastern empire by Belisarius (535). So it remained till 827, the date of the beginning of the Saracen occupation. Syracuse itself was taken in 877; the last stronghold, Rametta, fell in 965. For nearly a hundred years the Moslem rule was not seriously disturbed, but at length George Maniakes was sent by the eastern empire to win back the island (1038). His army included many Normans, who saw with eager eyes the goodliness of the land. Town after town was taken—Messana, Syracuse, all save Panormus. The recall of Maniakes brought back a return wave of Saracen conquest, but at length, after much hard fighting, the Normans conquered the whole island; Panormus (Palermo) fell in 1071; Syracuse in 1085; Rametta (Noto), the last stronghold to hold out, in 1090. Robert Guiscard, son of Tancred of Hauteville, now took the title of Duke of Apulia and Calabria; his brother Roger, that of Count of Sicily. The Norman dominions were united under his son Roger, the great Count of Sicily, who took the title at Palermo in 1130 of 'King of Sicily and Italy.' He was followed by William the Bad (1154-66) and William the Good (1166-89), on whose death childless the Sicilians chose Tancred, an illegitimate grandson of King Roger. But Tancred died in 1194, whereupon the crown fell to the German Emperor Henry VI., who had married Constance, daughter of King Roger I. Henry forced the Sicilians to acknowledge him as king, and died in 1197, leaving the kingdom to his son Frederick, afterwards the famous Emperor Frederick II. On his death in 1250 the succession fell to his son Conrad, next to his grandson Conradin, under whom Frederick's natural son Manfred governed Sicily. The latter declared himself king at Palermo in 1258 on an unfounded report of Conradin's death. But the popes pursued him with rancorous enmity, and on the nominal and shameless fiction of over-lordship offered his crown for money to Richard of Cornwall, brother of Henry III. of England, and next to Henry's younger son Edmund. At length Pope Urban IV., a Frenchman, opened up the most unworthy chapter of Sicilian history by granting it (1264) to Charles, Count of Anjou. Manfred fell fighting heroically against the invader at Grandella near Benevento in 1266, and Anjou entered Naples in triumph. But Peter, king of Aragon, who had married Constance, the daughter of Manfred, laid formal claim to Sicily in her right. The government of the French proved intolerable to the Sicilians, and the massacre of the Sicilian Vespers (q.v.) opened up a long struggle, which ended with the crowning of Peter's son Frederick in 1296, and his being acknowledged at the peace of 1302 king of *Trinacria* for life. But he soon felt strong enough to resume his proper title of King of Sicily, and at his death in 1337 left the crown to his son Peter.

The Angevin House continued to reign in Naples, although they still maintained their nominal claim to Sicily—hence after the union the name Kingdom of the Two Sicilies. They upheld the Guelphic party; the Aragonese in Sicily, set up against the pope, were Ghibellines. Frederick's successors reigned on in Sicily, but in 1409 Mary, queen of Sicily, married Martin, son of Martin of Aragon, and through this the island was again united to the crown of Aragon. Queen Joanna II. of Naples, successor of Ladislas, was childless by both her marriages, and had first adopted as her successor Alfonso V., king of Aragon and Sicily, then revoked this disposition to adopt Louis III. of Anjou. The two parties went to war and divided all Italy: the Duke of Milan and Sforza on the Angevin side, the pope and the Florentines on Alfonso's. On the death of Louis the queen adopted his brother René of Anjou in his place. She died in 1435, and seven years later Alfonso succeeded in taking Naples, and died in 1458 king of Aragon, Naples, and Sicily. He left Aragon and Sicily, which he had inherited, to his legitimate son John II.; Naples, which he had won, to his bastard son Ferdinand I., whose cruelty made the chief citizens invite John of Calabria, son of René, to contest the crown. He was unsuccessful, but Charles VIII. of France revived the claim as the representative of the Angevin House, entered Italy in 1494, and made his progress in triumph to Naples, whence King Alfonso II. fled. Next year Alfonso's son Ferdinand II. returned to Naples to win back his kingdom. He died in 1496, and was succeeded by his uncle Frederick, who was betrayed by his kinsman Ferdinand of Aragon making an alliance with Louis XII. of France, and compelled to retire, giving up his rights to the French king. Next year (1502) the French and Spaniards quarrelled over their ill-gotten spoil, and the war was ended by the Spaniards utterly defeating the French at Mola near Gaeta in 1504.

Ferdinand the Catholic had thus again united Naples and Sicily to the Spanish monarchy. Both himself and his successor, the Emperor Charles V., had promised not to exact any new taxes from the kingdom of Naples without consent of nobles and people; but the viceroy of Philip IV. laid on grievous burdens, which at last led to insurrections both in Naples and Palermo, crushed mercilessly by Don John, bastard son of Philip IV. In 1700 Charles II. of Spain died childless, whereupon Louis XIV. claimed the throne for his grandson Philip, Duke of Anjou, and the Archduke Charles of Austria for himself. The long war of the Spanish succession was closed by the peace of Utrecht (1713), which gave to Charles, now the Emperor Charles VI., Milan, Naples, and Sardinia, while the Duke of Savoy received Sicily with the title of king. Philip again plunged into Italian intrigues, and captured Sardinia by a treacherous attack. But the Quadruple Alliance (England, France, the United Provinces, and Charles of Austria) enforced the treaty. Victor Amadeus of Savoy had been on the side of Spain in hopes of gaining Lombardy, and the Powers compelled him in 1720 to give up his new kingdom of Sicily to Charles VI. in exchange for Sardinia. Don Carlos, son of the queen of Spain, after a series of intrigues, made an attack on Sicily, and at length in a readjustment of the map of Italy at the treaty of Vienna (1738) was acknowledged king of the Two Sicilies. As Charles III. was called to be king of Spain in 1759 he left Naples and Sicily to his younger son, Ferdinand IV., whose queen, Caroline, a sister of Marie Antoinette, naturally hated the French Revolution, and joined the English alliance. Bonaparte took Naples in 1798. King Ferdinand was turned out, allowed to return, but again turned out in 1806, when Bonaparte made his brother Joseph king. When Joseph was made king of Spain in 1808, Joachim Murat succeeded to his crown, Ferdinand being allowed to remain king of Sicily. By the treaty of Paris Italy was restored to her old masters. Victor Emmanuel received Sardinia with Genoa; the kingdom of Naples was restored to King Ferdinand IV. of Sicily, and he formally took the title of Ferdinand I. as king of the Two Sicilies. Ferdinand II. (1830–59) ruled Naples and Sicily with dreadful tyranny, bombarded Messina and Palermo, and flung the best citizens to rot in loathsome dungeons. Francis II. succeeded him; he had been brought up by the Jesuits, and under his rule the country ripened fast for revolution. At length Garibaldi sailed from Genoa with his thousand heroes, landed at Marsala, 11th May 1860, took Palermo, and at Melazzo defeated the king, who in abject terror promised all manner of reforms to Cavour and Victor Emmanuel. They did nothing but wait the issue, while Garibaldi crossed to Spartivento, drove back the king's troops, defeated them at Volturno, and entered Naples in triumph on the 7th September. The people of Sicily and Naples joined themselves by a popular vote of more than a hundred to one to the Sardinian kingdom.

The palmiest age of letters in Sicily was the reign of the first Hiero (478–467), besung by Pindar; the next, that of the elder Dionysius, himself a poet and the friend of Plato. The lyric, the comedy, and the mime were practised by Stesichorus of Himera, Epicharmus, and Sophron of Syracuse; Empedocles of Agrigentum was a famous philosopher, Archimedes of Syracuse the most celebrated of ancient mathematicians; but the rarest flower that grew out of Sicilian soil was the bucolic poem which once for all attained perfection in the idylls of Theocritus and Moschus of Syracuse, and in Bion, who, though a native of Smyrna, was a Syracusan in all his sympathies and in his grave.

The modern Sicilian dialect is of course closely allied to the Neapolitan, but offers grave difficulties both in vocabulary and grammar to the student acquainted only with Tuscan. It has furnished a rich literary material to the popular imagination for six hundred years down to our own day, and yielded a harvest of genuinely popular poetry not equalled elsewhere in the world. But not in their number alone are the Sicilian folk-songs pre-eminent, but in their intrinsic poetic excellence. The love-songs especially are tender, passionate, and sincere, and many have a penetrating pathos that haunts the memory of a reader. They have been collected by S. Salomone-Marino, Dr Pitrè (q.v.), and L. Vigo, whose *Raccolta ampliss. di canti popolari Sicil.* (1870–74) alone contains 6000 songs, with besides a good bibliography of books in the Sicilian dialect. Dr Pitrè's great *Biblioteca della Tradizioni pop. Siciliane* (19 vols. 1870–90) is a vast encyclopædia of folk-songs and ballads, folk-tales, legends, proverbs, customs, games, jests, riddles, &c., with grammatical introductions and glossaries. Two other works that must be named are Laura Gonzenbach's *Sicilianische Marchen* (2 vols. Leip. 1877), and S. Salomone-Marino, *Storie popolari in Poesia Siciliana* (Bolog. 1877). For the Sicilian dialect, see the works by Wentrup (Halle, 1880) and C. Avolio (Moto, 1882); the Sicilian-Italian Dictionaries of G. Biundi (Pal. 1857) and V. Mortillario (new ed. Pal. 1879).

There are histories of Sicily in antiquity by Holm (2 vols. Leip. 1870–74) and W. Watkiss Lloyd (1872); the Moslem period, by Amari (3 vols. Florence, 1853–73); the Norman period, by Bazancourt (2 vols. Paris, 1846) and Graf v. Schack (2 vols. Stuttg. 1889); the Bourbon period, by Amari (Paris, 1849); the Piedmontese period, by Querner (Bern, 1879). See also the works on the history of Naples by Giannone and his continuator, Colletta; Seibert, Reuchlin, Orloff, Rüstow, Romano-Manebrini, La Lumia, E. A. Freeman's unfinished *History of Sicily* (vols. i.–iii. 1891–92), and his short history ('Story of the Nations' series, 1892).

Sickingen, Franz von, born on 2d March 1481 at the castle of Ebernburg near Kreuznach, fought in 1508 against the Venetians in the service of the Emperor Maximilian, but in peace led the life of a free-lance. He could bring 20,000 followers into the field, and during 1513-19 we find him warring against Worms, the magistrates of Metz, the Landgrave Philip of Hesse, and Würtemberg. He twice levied ransoms of 20,000 and 30,000 gulden, and Charles V.'s election to the imperial crown was largely due to his influence. Reuchlin was protected by him at the capture of Stuttgart, and he formed a close friendship with Ulrich von Hutten (q.v.), who from 1520 was his constant guest, and won over his rude but lofty spirit to the cause of the Reformation. His fortresses, Landstuhl and Ebernburg, became the 'asylums of righteousness;' Bucer, Aquila, and Œcolampadius found refuge within their walls. In 1521 he assisted the emperor in his French campaign; in 1522, with the nobles of the Upper Rhine, he opened a Protestant war against the archbishop of Treves. That war miscarried; and put to the ban of the empire, and besieged in his castle of Landstuhl, on 2d May 1523 he received a musket-shot, of which six days later he died. In 1889 a stately monument to him and Hutten was erected at Ebernburg.

See works cited at Hutten, and monographs on Sickingen by Ulmann (Leip. 1872), Bremer (Strasb. 1885), and Hüll (Ludwigsh. 1887).

Sickle. See Reaping.

Sicyon, an important city of ancient Greece, stood on a triangular plateau, between the rivers Asopus and Helisson, about 2 miles S. of the Corinthian Gulf and 7 NW. of Corinth. It was celebrated in antiquity for the unusual beauty of its bronze work, which exercised an important influence on the development of Greek art in general, and was the seat of a school of painting that included Pamphilus and Apelles, both natives of Sicyon. It was also the birthplace of Aratus (q.v.), the general of the Achæan League, and of Lysippus, the sculptor. There exist at the present day a few remains of the ancient city, as well as of the more modern buildings erected by the Roman conquerors of Greece. These have been in part excavated by the American School of Classical Studies at Athens since 1887.

Siddhartha. See Buddhism, Vol. II. p. 517.

Siddons, Sarah, the greatest tragic actress England has produced, was the daughter of Roger Kemble, a respectable manager of a small travelling theatrical company, whose circuit was in the midland and western parts of England. Sarah, who was the eldest child, was born at Brecon on 5th July 1755. From her earliest childhood she was a member of her father's company, and in a playbill dated 12th February 1767 her name appears as acting the character of the Princess Elizabeth in Havard's tragedy of *Charles the First.* When only seventeen she formed an attachment to Siddons, who was a member of her father's company, and, after considerable opposition from her parents, she was married to him in Coventry on 26th November 1773. Her husband and herself joined the Cheltenham Company, and while here she was recommended to Garrick by the Earl of Ailesbury. Garrick asked the Rev. Bate Dudley to report on her abilities, and is said to have also sent King, the actor, to see her. The result was an engagement at Drury Lane, where she made her first appearance on 29th December 1775 in the character of Portia. It has been said that the comparative failure which attended her first attempt to become a London actress was the result of pique on the part of Garrick; but there is no evidence whatever of this, and the fact seems to be simply that her powers were not matured sufficiently to enable her to produce an effect in the huge metropolitan theatre. At the end of the season she was not re-engaged, and for six years she played in the provinces, making her greatest successes in York and Bath; but her reputation grew so fast that in 1782 she was invited to return to Drury Lane. She accepted the offer, and made her reappearance on 10th October 1782 as Isabella, in Garrick's adaptation of Southerne's *Fatal Marriage.* Her success was immediate and permanent, and from this time to her retirement she was the unquestioned queen of the stage. In 1803 she followed the fortunes of her brother, John Philip Kemble, who had purchased a share in Covent Garden Theatre, and here she appeared on 27th September 1803 in her favourite character of Isabella. During the rest of her career she continued at Covent Garden, and at that theatre she took her formal farewell of the stage on 29th June 1812, when she played Lady Macbeth. She appeared occasionally after this time, but only for charitable objects or for special benefits. After her retirement from the stage Mrs Siddons gave occasional public readings from Shakespeare and Milton. She died on 8th June 1831, and was buried in Paddington Churchyard. As an actress Mrs Siddons stands unapproached, so far as can be judged from recorded criticism, in every line of tragedy—her pathos, her rage, her despair, her suffering, her grief, all being perfect in expression and convincing in naturalness. Endowed by nature with a gloriously expressive and beautiful face, a queenly figure, and a voice of richest power and flexibility, she worked assiduously to cultivate her mental and physical gifts until she reached a height of perfection which has probably never been surpassed by any player of any age or country. In comedy she was less successful. See Life by Mrs Kennard ('Eminent Women' series, 1886).

Side-bones are enlargements situated above the quarters of a horse's feet, resulting from the conversion into bone of the elastic lateral cartilages. They occur mostly in heavy draught horses with upright pasterns, causing some stiffness, but, unless when of rapid growth, little lameness, though they are accounted amongst the defects that render a horse 'unsound.' They are treated at first by cold applied continually, until heat and tenderness are removed, when blistering or firing must be resorted to, and removal of pressure by shoeing with a 'bar shoe.'

Sidereal Clock, a clock so regulated as to indicate *sidereal time;* see Day. The sidereal clock is a most important aid to the practical astronomer, and is one of the indispensable instruments of an observatory.

Sideroxylon. See Ironwood.

Sidesaddle-flower is a name sometimes given to a plant of the genus Sarracenia. See Insectivorous Plants.

Sidgwick, Henry, a writer on ethics, was born at Skipton in Yorkshire, on 31st May 1838, and educated at Rugby and Trinity College, Cambridge, being elected a Fellow in 1859. From 1875 he lectured in the capacity of prælector of Moral and Political Philosophy, and in 1883 was elected Knightbridge professor of Moral Philosophy. His name first became widely known as an able writer on ethical subjects by his *Methods of Ethics* (1874; 4th ed. 1890), a critical examination of the principles underlying the various historic systems of moral philosophy, in which the points of resemblance between the opposing intuitional and utilitarian schools are particularly dwelt upon. The writer is on the whole fair to both sides, although his own sympathies lean to the utilitarian standpoint. The strongest feature of the book is its keen analytical power, which, however, drifts at times into the over-refinements of mere intellectual subtlety. Professor Sidgwick has contributed numerous papers on ethical and economic subjects to *Mind*, *Journal of Philology*, and other journals. He takes a warm and active interest in the higher education of women, and has been especially interested in the management of Newnham College at Cambridge. In 1886 he published as a separate book *Outlines of the History of Ethics*, the historical summary of the chief ethical systems and schools that he contributed to the ninth edition of the *Encyclopædia Britannica*; in 1883 *The Principles of Political Economy*, a work that maintains the essentials of John Stuart Mill's method and results, but modifies them into harmony with the march of progress and the advance in economic ideas; in 1891 *The Elements of Politics*. Professor Sidgwick is president of the Psychical Research Society, in which he takes an active personal interest.

Sidi-bel-Abbès, a quiet modern town of Algeria, 48 miles by rail S. of Oran and 56 NE. of Tlemçen. Pop. 19,848.

Sidlaw Hills. See FORFARSHIRE, and DUNSINANE.

Sidmouth, a watering-place on the south coast of Devonshire, 14 miles by road, but 20¾ by a branch-line (1874), ESE. of Exeter. It lies in a narrow valley at the mouth of the little Sid between the red sandstone cliffs of High Peak (513 feet) on the west, and Salcombe Hill (497) on the east. Its esplanade is protected by a sea-wall (1838), 1700 feet long; and its parish church (1259; almost rebuilt 1860) has a stained west window inserted by Queen Victoria in memory of her father, the Duke of Kent, who died here in 1820. Sidmouth then was the favourite resort that it has once more become since the opening of the railway; its former prosperity as a port, which in Edward III.'s day sent two ships to the siege of Calais, passed away through the silting up of the harbour. The climate is mild, the rainfall the least in Devon, and the beach yields plenty of agates and chalcedonies. Pop. (1851) 2516; (1891) 3758.

Sidmouth, HENRY ADDINGTON, VISCOUNT, prime-minister, was born in London, 30th May 1757, the son of Lord Chatham's physician, Dr Anthony Addington (1713–90). After twelve years at Cheam and Winchester schools, and four at Brasenose College, Oxford (1774–78), he studied law at Lincoln's Inn, married (1781), and was led by his friendship with Pitt to quit the bar for politics, in 1783 being elected M.P. for Devizes. He made an admirable Speaker from 1789 till 1801, when, upon Pitt's resignation on the Catholic relief question, he was invited by the king and urged by Pitt to form a ministry. That most third-rate administration, in which Addington was First Lord of the Treasury and Chancellor of the Exchequer, and whose one great event was the short-lived peace of Amiens (1802), came to an end in 1804. In the following January Addington was created Viscount Sidmouth; and thereafter he was thrice President of the Council, once Lord Privy-seal, and from 1812 to 1821 Home Secretary, as such being thoroughly unpopular for his coercive measures. He retired from the cabinet in 1824, and died 15th February 1844. He was a very sincere Tory. See his *Life and Correspondence* by his son-in-law, Dean Pellew (3 vols. 1847).

Sidney, or SYDNEY, ALGERNON, grand-nephew of the famous Sir Philip, was born probably at Penshurst, Kent, and in 1622, the second son of Robert, second Earl of Leicester (1595–1677). He received a careful education, and accompanied his father in 1632 on his embassy to Denmark, and in 1636 to France. In 1641–43 he commanded a troop of horse against the rebels in Ireland, of which country his father was (nominally) Lord-lieutenant. Then with his elder brother, Viscount Lisle, he returned to England, and, declaring for the parliament, was in March 1644 appointed to a troop in the Earl of Manchester's regiment. At Marston Moor he was severely wounded; in 1645 was appointed governor of Chichester, and returned by Cardiff to parliament; in 1646 attended his brother, now Lord-lieutenant, to Ireland as lieutenant-general of the horse and governor of Dublin; and in 1647, after receiving the thanks of the House of Commons for his services, was appointed governor of Dover. In 1649, though nominated one of the commissioners, he kept himself clear from any hand in the king's trial, which yet he justified on abstract grounds, speaking afterwards of the execution as 'the justest and bravest action that ever was done in England or anywhere else.' In principle a severe republican, he resented Cromwell's usurpation of power, and from the dissolution to the restoration of the Long Parliament (1653–59) lived in retirement at Penshurst. He then was nominated one of the Council of State, and next was engaged for a twelvemonth on a political mission to Denmark and Sweden. After the Restoration he lived precariously on the Continent, flitting from place to place (Rome, Brussels, Augsburg, Montpellier, Paris, &c.); but in 1677 a pardon was procured for him from Charles II., and he returned to his native country. In 1679 he twice stood for parliament, but each time was jockeyed out of his seat in favour of the court candidate; and an attempt was made that same year to involve him in the sham Meal-tub Plot. The attempt miscarried; still, he deemed it prudent to retire for a while to France, where he bought a small property, and, to detach Louis XIV. from Charles, entered into negotiations with him through Barillon. That prior to this he had taken moneys from the French ambassador, either for himself or (more likely) for the republican cause, is admitted by Hallam and Macaulay, but disputed by Mr Ewald, who contends that Barillon embezzled the thousand guineas that he set down to Sidney's account. Anyhow, to understand Sidney's relations with Louis, it must be borne in mind that he was hardly less hostile to William of Orange, as stadtholder, than to Charles himself, as king. Next year he was back in England, and soon after his return drew up for his friend, William Penn, the Pennsylvanian constitution, features of which were the ballot, universal suffrage, the abolition of a property qualification, religious equality, prison reform, and the abolition of capital punishment for all crimes save murder and treason. In June 1683, when the Rye-house Plot was announced, the chance was seized to get rid of men felt to be dangerous, and, along with Lords Russell, Essex, and Howard, Sidney was arrested and committed to the Tower. On 21st November he was tried for high-treason before the brutal Jeffreys, and, on no evidence but the traitor Lord Howard's and his own unpublished *Discourses concerning Government*, was found guilty and sentenced to die. He met his doom bravely on Tower Hill, 7th December, and was buried the next day at Penshurst. His attainder was reversed in 1689; his *Discourses* appeared first in 1698.

See Blencowe's *Sidney Papers* (1813), and the Lives of Sidney by S. W. Meadley (1813) and A. C. Ewald (2 vols. 1873), with other works cited at RUSSELL, SHAFTESBURY, and CHARLES II.

Sidney, PHILIP (November 1554–October 1586). After three hundred years the effacing hands of time and change have still left a halo about Sir Philip Sidney such as surrounds no other of his contemporaries. His unselfish chivalrous nature it is, bold at once and tender, his purity of life in the corrupt atmosphere of the Elizabethan court, above all, his heroic death, which make him still in a certain sense alive among us. Yet his was in fact an unadventurous life, wasted, not by his own fault, despite of strenuous endeavour; whilst by a kind of pathetic irony the fame which preserves his gracious memory has perversely failed to do justice to that true and passionate verse which in his own day placed him at the head of our poetry next in succession to Chaucer. Sidney, born 29th November 1554, at Penshurst, Kent, and named after Philip II., was son to Sir Henry, a man of high birth and noble character, married to Mary Dudley, daughter to the Duke of Northumberland (executed for treason 1553), and sister to that base and hypocritical Lord Leicester, of all Queen Elizabeth's favourites the most ill-chosen and baleful. Philip was sent first for education to Shrewsbury School (1564), thence (1568) to Christ Church, Oxford. He studied hard, as his writings show, and made his two best friends, Greville, afterwards Lord Brooke, and Dyer; men likeminded with himself in a certain seriousness and manliness of character, such as was naturally formed by the atmosphere of that age—troubled, yet full of hope and energy.

From 1572 to 1575 Sidney travelled in France, Germany, and Italy, completing his education after the fashion of those days, returning well versed in the best Italian literature, but unspoiled by foreign temptations. He was not a man to verify the proverb of that day, 'A devil incarnate is the Englishman Italianate.' Few men or none were then more powerful in England than his uncle Leicester, and Sidney at once began to make his career at court, then the only portal to public life. His character was now fully formed as the model of a finished English gentleman; in Spenser's fine phrase he was the 'President of noblesse and of chivalry.' Yet as a statesman Sidney practically failed. At first a favourite of the ever-fickle queen, he accompanied her progresses; he was sent ambassador (1577) to Rudolph II., and then to William, Prince of Orange. There is a vague story that he was thought of as candidate for the uneasy Polish throne; he certainly longed to join Prince Casimir, then in arms in the Netherlands. But he was not yet (1578) fated to visit Zutphen.

Sidney's court position now became trying. Elizabeth displayed her too frequent ingratitude toward his father for his exertions as Lord Deputy in Ireland, and Philip wrote in his defence with much ability and courage. And in similar style he addressed the queen against her desired match with the miserable Duke of Anjou. Elizabeth hence frowned upon him; whilst, meanwhile, Leicester's own marriage with Lady Essex had removed him from court. Sidney also retired (1580) to his admirable sister Mary, now Lady Pembroke, at Wilton, where most, probably, of his *Arcadia* was written.

Of Sidney's life in 1581-82 we know little. He returned to court, like Spenser,

> To lose good days, that might be better spent;
> To waste long nights in pensive discontent:

tortured also with the hopeless love, which we shall notice further on. In 1583 he was knighted; he received from Elizabeth a paper-grant of 30,000,000 acres in 'certain parts of America not yet discovered;' and married Frances, daughter to Sir F. Walsingham. But although he may thus have thought to strengthen his position, Sidney was doomed to yet another disappointment. The arrangement which he had settled (1585) to accompany Drake on one of his buccaneer expeditions to America was defeated by Elizabeth's weakness or caprice and Drake's jealous treachery. Indeed, when seen not through the haze of tradition, the distorting mists of partisanship, but in natural light, the popular heroes of that day often drop their halo. But this subject belongs to that unwritten section of our annals, the true history of the Elizabethan age.

It was poor amends that Sidney was ordered to accompany Leicester, chosen for her general by the queen's infatuation, to carry her half-hearted and untrustworthy support to the Netherlanders in their agony and struggle against Spain. Upon the miseries of Sidney's position in his partial charge of that thrice disgraceful expedition we need not dwell. For nearly a year he was detained in idleness; then, after one small brilliant exploit, he received upon October 2, 1586, his death-wound in a chivalrous conflict, rash as the English charge at Balaclava, under the walls of Zutphen; dying, as he had borne himself throughout life, like a hero and a Christian, on the 17th; and mourned by England with a unanimity and a depth of feeling never surpassed—perhaps never equalled.

By 1579 Sidney, who through a Cambridge scholar, Gabriel Harvey, had become acquainted with Edmund Spenser, a year or more his senior, had formed with him and some others a little literary society, which aimed at rejecting rhyme and writing English poetry in classical metres. Of that folly Sidney soon repented; but a few letters between Spenser and Harvey upon the subject, happily preserved, are noteworthy as the sole contemporary notice of Sidney's own work in literature, which we may place between 1578 and 1582. Widely celebrated as that work was during Sidney's lifetime, yet nothing of it was published till after his death. He 'purposed no monuments of books. . . . His end was not writing, even while he wrote,' said his friend Greville. Like his immediate predecessors Wyatt, Surrey, Sackville, he was statesman or courtier first, author only in leisure hours. His writings must have been partially made known by MS. circulation; yet we may suspect that Sidney's own brilliant character, his connections, which placed him in the very foremost rank of high life, his generous patronage of men of letters, with the report of those to whom his writings were communicated, united to give him his pre-eminent contemporary reputation. This was, however, amply supported when the *Arcadia* (written for his sister, Lady Pembroke, probably 1578-80, but never finished) appeared, imperfectly in 1590, completely in 1598. This book, for perhaps about a century, retained a vast popularity, though now almost unread, and indeed unreadable. It is a pastoral romance, founded primarily upon the *Arcadia* (1504) of the Neapolitan Sannazzaro, being, like that, an intricate love-story, intermixed with poems and written in melodious but elaborate prose, and not free from the artificial 'conceits,' the Euphuism, familiar in Europe to that age. But the Portuguese Montemayor's *Diana* (1542), the old Greek romance *Theagenes and Chariclea*, with, doubtless, other traditional legends, had also their share in Sidney's story; whilst its many incidents, disguisals, and intricacies supplied material for later writers. But the main value of the book perhaps lay in this, that here Englishmen found their earliest model for sweet, continuous, rhythmical prose—for the prose of art. Before the *Arcadia* we have fine single passages; no such consistent whole. The verse portions are rarely happy; they must have been among Sidney's earliest attempts; but in truth his genius required that high heat of personal passion which inspires Astrophel to fuse his ore into gold; although that ore (to pursue the figure) is always weighty with Sidney's seriousness, his elevated thought, his chivalry of nature. As of exceptional merit may be noticed the dialogue between Nico and Dorus, and an Epithalamium of stately dignity, which may have been suggestive to Spenser. In *Arcadia* Sidney tried numerous metres, English, Italian, classical; the latter, inevitably, with small success.

To about 1580 may be assigned Sidney's *Apology for Poetry* (afterwards named *Defence of Poesy*), in reply to an abusive Puritan pamphlet, and to a general disesteem then felt in England for that art; published 1591. In this tract, written in clear, manly English, and still well worthy of readers, Sidney defines poetry, after Aristotle, as Ideal Imitation, and for her claims her ancient place as the highest mode of literature, teaching mankind the most important truths through the medium of that pleasure which is the formal end of all fine art. In mediæval fashion, many authorities are quoted, and Sidney displays his wide range of reading. Lastly, he criticises severely and justly the crowd of contemporary versifiers—not peculiar to that age!—to whose want of power, bad taste, and trivial style he partly ascribes the then existing low estimate of poetry. And here he names the best English poets known to him: Chaucer, Sackville, Surrey, and Spenser's just (anonymously) published *Calender*. 'Besides these, I do not remember to have seen but few (to speak boldly) printed, that have poetical sinews in them.' English drama, it will be remembered, was then in its cradle.

Sidney, like Shelley, was so great a poet that he had just right to come forward in defence of poetry. But for himself it was love, not instruction, that moved him:

> Come, let me write: And to what end? To ease
> A burthen'd heart;

and again, to his Love,

> Only in you my song begins and endeth.

For the origin of *Astrophel and Stella* (published 1591), however, we must go back to an episode in Sidney's life. In 1575, aged twenty, he met Penelope Devereux, daughter to Lord Essex, then a child of twelve. Some intimacy followed, and Essex, on his deathbed (1576), expressed a hope that the two might in due time marry. In Sidney's nature, however, was some want of youthfulness; his heart did not respond, and it was only in 1581, when Penelope was engaged and wedded (apparently without love on her part) to Lord Rich, that Sidney awoke too late to find *Quid sit Amor*—to find also that she might have loved him. It is hence a sad drama, a miniature tragedy in lyrics, that is revealed in this long series; as Nash, the editor, said, 'The argument, cruel chastity; the prologue hope, the epilogue despair.'

These 108 sonnets and 11 songs (to which a few separately published in 1598 may be added), after, or rather with, Shakespeare's sonnets, have long seemed to us to offer the most complete and powerful picture, in this form, of passionate love, in our language. And they have a straightforward truth of expression which unveils the poet's own character beyond Shakespeare's: they truly speak everywhere heart to heart. Sidney's *Canzoniere* has hence escaped those elaborate futile attempts to give it an impersonal or symbolical character which have wearied mankind in the case of Shakespeare. Yet, as Dante's love for Beatrice, Petrarch's for Laura, have been doubted, so has it been with Astrophel's for Stella. But readers who do not bring only brains to reading Sidney's little *Liber Amoris* will assuredly set aside every such ingenious sophist and sceptic at once and for ever: He has not loved!

Considering the charm that Sidney's name still exerts, the close relation of his poetry to the romance of his life, and the high place in our literature merited by its great qualities, that as poet he should have met hitherto so imperfect a recognition is little to the credit of popular taste. That high place has been amply vindicated in the admirable essay by the most exquisite of poetical critics, Charles Lamb. But that Sidney's fame falls far below his deserts is due in part to that inequality of his workmanship which he shares with other supreme writers of sonnet sequences; with Petrarch, Shakespeare, and Wordsworth. Nor did life allow him to acquire their finished art. 'His end was not writing, even while he wrote.' Fanciful conceits, obscurity from the depth and wealth of thought, are not unfrequent; at times the style is prosaic, bare, unmelodious. But over-fancifulness was the defect of that age: obscurity is common to his great rivals, when moving in the sonnet's narrow bounds. It is the defect of high thinking and intensity of passion. Space, however, does not allow us to offer even a few specimens in proof; and, after all, the poet is always his own best interpreter.

Sidney's Poetry and *Apology* have been carefully edited, the first by the Rev. A. B. Grosart (3 vols. 1877), the second by Mr Arber (1868) and Mr Shuckburgh (1891); the last complete *Arcadia* was printed so long since as 1725. Dr H. Oskar Sommer published in 1891 a photographic fac-simile of the original quarto edition of 1590. Fulke Greville's Life (1652) was re-edited by Sir Egerton Brydges (2 vols. 1816). Modern Lives are by Dr Zouch (1808), H. R. Fox Bourne (1862; also a smaller book in 'Heroes of the Nations,' 1891), and J. A. Symonds in 'English Men of Letters' (1886). An elaborate life by Dr Ewald Flugel was announced in 1891 by the Clarendon Press as in preparation. See also the *Sydney Papers* edited by Arthur Collins (1746), and the Correspondence of Sir Philip Sidney with Hubert Languet, edited by Steuart A. Pears (1845). See also the article ZUTPHEN.

Sidon (Heb. *Zidon*), anciently a city of Phœnicia, situated on the east coast of the Mediterranean, half-way between Tyre and Beyrout. It soon rose, both by its exceptional position and the enterprising character of its inhabitants, to the first position among the cities of Phœnicia (q.v.), so that the whole country is sometimes designated by the name of Sidon, 'the Great,' 'the Metropolis.' The extensive commerce of Sidon is well known from ancient authorities. Its colonies extended over the coast of Asia Minor, the adjacent islands, Thrace and Eubœa, and even some parts of Sicily, Sardinia, Spain, northern Africa, in fact, nearly the whole of the ancient world. The Sidonian manufactures of glass and linen, purple dye and perfumes, were sources of vast wealth. At length it surrendered to Shalmaneser, king of Assyria. But under Assyrian, Chaldean, and Persian domination it retained a kind of independence for its internal affairs, and under the Persians reached its highest prosperity. An unsuccessful revolt against Artaxerxes Ochus ended in its temporary ruin (351 B.C.). Speedily rebuilt and repeopled, it opened its gates to Alexander the Great (333 B.C.), and from that time forth it fell successively into the hands of Syrian, Greek, and Roman rulers. Through the middle ages little is heard of it, except that it was taken by the Crusaders. The present town of Saida has 10,000 inhabitants, of whom 7000 are Mohammedans. In the neighbourhood are numerous rock-cut burial-places of the ancient Phœnicians, in which have been found the sarcophagus of Eshmunazar, king of Assyria, and others. The town was stormed by the allies under Napier in 1840.

Sidonius Apollinaris, a 5th-century churchman and author, descended from a noble Gaulish family, who held high civil offices at Rome and in 472 became bishop of Clermont. Born about 430, he died in 483. His letters (nine books) are modelled on Pliny and other classics; his poems (twenty-four books) comprise panegyrics on three emperors and two bombastic epithalamiums.

See the Abbé Chaix, *Saint Sidoine Apollinaire et son Siècle* (2 vols. Clermont, 1867–68); works by Chatelain (Paris, 1875) and Kaufmann (Gottingen, 1864); Hodgkin's *Italy and her Invaders* (vol. ii. book iii.; 1880). There are editions of the works of Sidonius by Baret (Paris, 1879) and Lütjohann (Berlin, 1888).

Siebenbürgen ('Seven Castles'), the German name of the former principality of Transylvania.

Siebengebirge, or 'Seven Mountains,' in Rhenish Prussia, on the right bank of the Rhine, about 20 miles above Cologne. The highest is the Ölberg (1522 feet); but the most famous is the Drachenfels (q.v.). The crags are crowned with ruins of baronial castles of the 12th century. Trachyte is quarried amongst these hills; from them the stone was obtained for the greater part of Cologne Cathedral.

Siebold, PHILIPP FRANZ VON, physician and botanist, was born at Wurzburg, 15th February 1796, became sanitary officer to the Dutch in Batavia, and, accompanying the Dutch embassy to Japan, did much to make Japan known to the western world. He spent 1826–30 in Japan, wrote on the country, its flora, and language, and died 18th October 1866.—His brother KARL THEODOR ERNST VON SIEBOLD, anatomist, was born 16th February 1804, and became famous as professor at Munich (1853), where he died, 7th April 1885. He wrote works on the Invertebrata (Eng. trans. 1857), on tapeworms, on parthenogenesis, on salamanders, and on the fresh-water fishes of central Europe.

Siedlce, a town, or rather a large village, of Poland, 57 miles by rail E. by S. of Warsaw, is the capital of the province of the same name. Pop. 12,950.—Area of *province*, 5535 sq. m.; pop. 671,538.

Siege (Fr., 'a seat,' 'a sitting down'). When the assault of a fortified place would be too hazardous and costly and its reduction by blockade too slow, recourse is had to the *regular siege* or *systematic attack*. In order to cross the open ground swept by the fire of the fortress with as little loss as possible the besieger makes use of sunken roads or *trenches*. The revetments having been breached by his artillery or mines, he continues these roads through the breaches into the place. To prevent these *approaches* being enfiladed by the guns of the fortress they are made at first in zigzags; the prolongations of which are directed so as to clear the works of the fronts attacked, and, when a direct advance becomes necessary, they are provided with traverses at short intervals, or *blinded sap* is used—i.e. a trench covered in with timber and earth. Two or three such lines of approach are used. To protect and connect them lateral trenches are formed from which large bodies of troops can fire upon any sortie that may be made. These are termed *parallels*, being parallel to the general front of the parts attacked. The *first* parallel is made at as short a distance as possible (perhaps 1000 yards) from the fortress, and its construction follows the disorganisation of the defenders' artillery by that of the attack from its first position, often 4000 yards from the fortress; the *second* would be rather less than midway between the first and the most advanced works of the fortress, so that the supporting troops in it may be nearer the working parties in the approaches than the enemy; the *third* parallel would generally be about 100 yards in front of the salients of the covered way. Parallels are useful also to connect the batteries which, dispersed over a wide area, will concentrate their fire upon the revetments of the ditch and ramparts, or upon the guns of the defence. These latter, restricted as they are to a comparatively small space, must eventually be outnumbered and overpowered; but, if the investment is imperfect, as at the siege of Sebastopol in 1854–55, an active defender may long delay this disaster, especially if the fortress has an outer girdle of detached forts, for in that case at least two of the forts must be taken by regular siege before further advance is made, and the ground between them (1000 yards and upwards) lends itself to the construction of new batteries to meet those of the attack. But the resources in men, guns, and ammunition must, by the nature of the case, be largely in favour of the attacker, and therefore, if persevered in, the siege is sure to succeed.

The ancients used to surround the place attacked with a high bank of earth, called a *line of circumvallation*, and protected themselves against attack from the outside by another called a *line of contravallation*, and a similar arrangement was in vogue until the middle of the 19th century. Now a covering field-army is employed, which, by its greater mobility, is able to meet the relieving army many miles from the besieging force, and a chain of fortified localities takes the place of the continuous line of circumvallation.

In order that a siege may be safely undertaken the strength of the besieger should be about four times that of the garrison. Thus, in the case of a small place with a garrison of 5000 men the line of investment would probably be 12 miles long, and could be maintained by three detachments of 2500 men each, the guards of the trenches would be 5000 and working parties 8000—a total of 20,500. In 1870 Strasburg, with a garrison of 20,000, was captured by a besieging force 60,000 strong. Metz was starved into surrender, the presence of so many men (some 170,000) besides the proper garrison only hastening that result. Had this large entrenched camp been held by its regular garrison of 40,000 men it would not have fallen to a besieger with less than 120,000, which is more than half the numbers actually employed.

The *siege trains* employed in 1870 by the Germans were comparatively small, owing to the badly prepared state of the French fortresses. Thus, at Strasburg only 243 pieces were used, firing 200,000 rounds in thirty-six days, while at Sebastopol the allies mounted 698 pieces of artillery, and in three days these fired 150,000 rounds.

The *siege parks*, or main depôts, for the artillery and engineer trains must be out of range of the enemy's guns, containing as they do powder, ammunition, guns, and warlike stores of all descriptions. The batteries necessary are *enfilade* batteries, placed on the prolongations of all the important works attacked; *counter* batteries, to overcome the fire of the works bearing upon the field of attack; *mortar* and *howitzer* batteries, to search by high-angle fire the interior of all the works attacked; and *breaching* batteries, to breach by curved fire the scarps and flanking casemates. Light pieces, such as the seven-pounder mountain gun and machine guns, are placed in the second and third parallels, and in the *demi-parallels* or lodgments, 100 to 150 yards long, made on each approach about half-way between these parallels.

Beyond the third parallel the besieger will probably be met by counter-mines, and himself have to resort to mining in order to carry out the crowning of the covered way. He will then connect his approaches by a fourth parallel, establish batteries and lodgments on the crest of the covered way, and from them mine down to the back of the counterscarp, which he can blow in previous to sapping across the ditch and up the breaches. From the positions thus gained a further advance, if necessary, can be made until the last retrenchment is taken, and the place falls. See also FORTIFICATION, and MINES.

Among great sieges in the world's history may be mentioned those of Troy, Tyre (572, 332 B.C.), Syracuse (396 B.C.), Saguntum (219 B.C.), Jerusalem (70 A.D.), Acre (1191, &c.), Calais (1347), Orleans (1428), Constantinople (1453), Haarlem (1572-73), Leyden (1574), Breda (1625), Rochelle (1628), Magdeburg (1631), Breisach (1638), Taunton (1644-45), Londonderry (1689), Gibraltar (1731, 1779, 1782-83), Prague (1741-44), Leipzig (1757, 1813), Quebec (1759-60), Seringapatam (1799), Genoa (1800), Saragossa (1808-9), Ciudad Rodrigo (1810, 1812), New Orleans (1814), Antwerp (1832), Rome (1849), Sebastopol (1854-55), Kars (1855), Lucknow (1857), Delhi (1857), Gaeta (1860-61), Vicksburg (1863), Charleston (1863-64), Richmond (1864-65), Metz (1870), Strasburg (1870), Belfort (1870-71), Paris (1870-71), Plevna (1877), and Khartoum (1884).

The *state of siege* as defined by continental jurists is a condition of things in which civil law is suspended or made subordinate to military law. A fortress, city, or district is thus put under martial law—i.e. under the authority of the military power—either on account of the presence of an enemy, as at a siege, or because of the failure of the civil power, as in the case of domestic insurrection, or of a conquered district in military occupation. The *minor state of siege*, a modification of the more severe rule, usually suffices for domestic troubles. No such provision is made by the laws of the British Empire or of the United States, though very similar powers are exercised when martial law is proclaimed. For this no rules are made—the possibility of civil war is not presupposed; but should the civil power become inoperative it is the duty of the supreme authority to maintain order by any means (usually of course an armed force) that are available, afterwards coming to parliament for an act of indemnity to justify conduct in itself contrary to law. Perhaps an approach to the continental *minor state of siege* may be found in the restricted power to try offenders in Ireland by military tribunals created by act of parliament in 1799, 1803, and 1833.

Siegen, a town of Prussia, in Westphalia, stands on the Sieg, 47 miles E. of Cologne, manufactures leather, paper, linen, soap, iron, copper, lead, zinc, &c., having many mines in the vicinity. Siegen was the birthplace of Rubens. Pop. 16,676.

Siegfried, or SIGFRID. See NIBELUNGENLIED.

Siemens, WERNER VON, engineer and electrician, was born December 13, 1816, at Lenthe in Hanover. In 1834 he entered the Prussian Artillery, and in 1844 was put in charge of the artillery workshops at Berlin. He early showed scientific tastes, and in 1841 took out his first patent for galvanic silver and gold plating. He was of peculiar service in developing the telegraphic system in Prussia, and discovered in this connection the valuable insulating property of gutta-percha for underground and submarine cables. In 1849 he left the army, and shortly after the service of the state altogether, and devoted his energies to the construction of telegraphic and electrical apparatus of all kinds. The well-known firm of Siemens and Halske was established in 1847 in Berlin; and subsequently branches were formed, chiefly under the management of the younger brothers of Werner Siemens, in St Petersburg (1857), in London (1858), in Vienna (1858), and in Tiflis (1863). Besides devising numerous useful forms of galvanometers and other electrical instruments of precision, Werner Siemens was one of the discoverers of the principle of the self-acting dynamo (see DYNAMO). He also made valuable determinations of the electrical resistance of different substances, the resistance of a column of mercury, one metre long and one square millimetre cross section at 0°C., being known as the Siemens Unit. His numerous scientific and technical papers, published in the *Proceedings* of the Berlin Academy (of which he became a member in 1874), in Poggendorff's *Annalen*, in Dingler's *Polytechnische Journal*, &c., were republished in collected form in 1881. In 1886 he gave 500,000 marks for the founding of an imperial institute of technology and physics; and in 1888 he was ennobled.

Siemens, SIR WILLIAM (KARL WILHELM), the youngest brother of Werner Siemens, was born at Lenthe in Hanover, April 4, 1823. He was educated at the trade school at Magdeburg, and spent a year in study at Göttingen University, where he worked hard at science. In 1843 he visited England, and was successful in introducing a process for electro-gilding invented by his brother Werner and himself. In 1844 he again came to England and patented his differential governor. Thenceforward he made England his home, and became a naturalised British subject in 1859. In 1862 he was elected a Fellow of the Royal Society, and was presented with the Royal Albert Medal (1874) and with the Bessemer Medal (1875) in recognition of his researches and inventions in heat and metallurgy. He filled the president's chair in the three principal engineering and telegraphic societies of Great Britain, and in 1882 was president of the British Association. He was knighted in April 1883, and died on November 19 of the same year. As manager in England of the firm of Siemens Brothers, Sir William Siemens was actively engaged in the construction of overland and submarine telegraphs. The steamship *Faraday* was specially designed by him for cable-laying. In addition to his labours in connection with electric lighting, Sir William Siemens also successfully applied, in the construction of the Portrush Electric Tramway (opened 1883), electricity to the production of locomotion. In his regenerative furnace (1856; see Vol. V. p. 240) he utilised in an ingenious way the heat, which would otherwise have escaped with the products of combustion. The process was subsequently applied in many industrial processes, but notably by Siemens himself in the manufacture of steel (see IRON). Of his miscellaneous inventions and researches, the following are particularly worthy of mention: A water-meter; a thermometer or pyrometer, which measures by the change produced in the electric conductivity of metals; the bathometer, for measuring ocean depths by variations in the attraction exerted on a delicately suspended body; and the hastening of vegetable growth by use of the electric light.

See the *Life* (1889) by William Pole, F.R.S.; and *The Scientific Works of C. W. Siemens, Kt., F.R.S.* (1889), edited by E. F. Bamber, C.E.

Sienna (Ital. *Siena*), a city of Italy, stands in the heart of Tuscany, 60 miles by rail S. of Florence. The streets are narrow, winding, and steep, and the city still preserves many features of mediæval times. It is surrounded by walls and defended by a citadel. The ground-plan of the market-place, where the principal public buildings are situated, resembles that of an ancient theatre. The chief architectural glory of Sienna is her cathedral, one of the finest examples of Gothic work in Italy. It was begun early in the 13th century; in 1339 it was intended to build a vastly larger church, of which the existing cathedral should have been only one transept. But after the plague of 1348 the idea was abandoned, and only ruined walls indicate the ambitious design. The magnificent west front of three arches was not finished until 1380; it is partly pointed, partly round-arched, and is enriched with red, white, and black marbles, gilding, and many sculptures. A fire did considerable damage to the exterior in 1890. A lofty square campanile stands on the south side. The art treasures of the interior embrace the wonderful octagonal pulpit by Niccolo Pisano (1268), similar to the one at Pisa; the marble mosaic floor of the cathedral, from designs by Buoninsegna and Beccafumi; the series of frescoes commemorative of the life of Pope Pius II., by Pinturicchio, in the Piccolomini Library, where also are preserved several choir books splendidly illuminated by Siennese artists; the celebrated font (1428), with bas-reliefs by Donatello, Della Quercia, and other sculptors, in the church of San Giovanni, situated beneath the cathedral. The churches of Sant' Agostino, the Servites, San Domenico, and some others contain pictures by Sodoma, Matteo di Giovanni, and other Siennese artists. The greatly venerated church of St Catharine (q.v., a native of this city) stands on the site of her former dwelling-house; and not far away is the fountain of Fontebranda, celebrated by Dante. The municipal palace, a magnificent edifice of brick in the Pointed Gothic style, begun in 1288 and finished in 1309, is adorned on the exterior by a lofty tower (1325), and contains numerous paintings by Siennese artists. There are several noble palaces, as the Piccolomini, Tolomei, Monte de' Paschi, Loggia del Papa, some dating from the 13th century, and some now put to various public uses. The more noteworthy of the public institutions are the university, with faculties of medicine and law (less than 180 students), founded in 1203; the state archives and the town library; and an Institute of Fine Arts (1816), sheltering in its gallery many fine pictures by masters of the Siennese school, the principal of whom are Buoninsegna, the brothers Lorenzetti, Simone di Martino, Matteo di Giovanni, Peruzzi, Sodoma (Bazzi), and Beccafumi. The city has also given birth to a host of other illustrious men, as Æneas Piccolomini (Pope Pius II.), Gigli (a scholar and a humorist), Bernardino Ochino, the two Socini (founders of Socinianism), and the architects Agnolo, Agostino, and Della Quercia. Every July (2d) and August (16th) celebrated horseraces are held in the market-place, being the survival of still more widely celebrated popular festivals of the middle ages. The inhabitants, 23,445 in 1881, weave silk, manufacture cloth and hats, and carry on an active trade in wine and olive-oil. Sienna is the seat of an archbishop.

Cathedral at Sienna.

Shortly before or after the establishment of the Roman empire Sienna was made a Roman colony under the name of *Sena Julia*. After the empire was broken up the city soon formed itself into a free republic, governed by consuls, and grew so much in power and prosperity that it became the head of the Ghibelline towns in Central Italy. During this period (the 12th and 13th centuries) it had a dangerous rival in Florence, but inflicted a crushing defeat upon the Florentine militia at Montaperto in 1260. A century later, however, when hard pressed by Florence, the Siennese put themselves (1399) under the protection of the Duke of Milan. Nevertheless hostilities were frequently renewed with their powerful rival during the 15th century. Between 1487 and 1512 the virtual ruler of Sienna was Pandolfo Petrucci, called the Magnificent, who aimed at founding a dynasty in his native city similar to that of the Medici in Florence; but his descendants were not the men to realise his ambitions, and in 1524 the people, to escape from the dominion of the Petrucci, put themselves under the suzerainty of the Emperor Charles V. Yet soon afterwards the city revolted and called in the French to its aid; but it and its ally were defeated and Sienna itself besieged (1555) and taken. The emperor then gave it to Cosimo de' Medici (1557), who annexed it to Florence, and subsequently incorporated it in the grand-duchy of Tuscany (q.v.).—The *province* of Sienna has an area of 1477 sq. m. and a pop. (1889) of 222,104.—For Sienna Earth, see BURNT SIENNA.

Sierra, the name applied in Spain and in Spanish-speaking countries to a range of mountains. It is usually derived from the Latin *serra*, 'a saw,' but more probably comes from the Arabic *sehrah*, 'a desert place,' whence also Sahara.

Sierra Leone, a British colony—since 1888 a separate and distinct colony—on the west coast of Africa, stretching 180 miles along the coast, from the French colony of Rivières du Sud in the north to the frontier of Liberia in the south, and with undefined limits towards the interior. The total area is estimated at 4000 sq. m. This includes the Los, the Banana, Tasso, Sherbro, and other islands off the coast. The name Sierra Leone is more strictly confined to a peninsula, 26 miles long by 12 broad, that projects to the north-west immediately south of the Sierra Leone (i.e. the river Rokelle) estuary. It rises to 3000 feet in Sugar Loaf Mountain, and both the peninsula and the mountain are covered with dense vegetation. The climate is very hot and very moist. The rains last from April to December, and the annual rainfall ranges from 144 to 170 inches. The thermometer varies between 64·5° and 100·5° F. The low-lying districts are infested with a good deal of fever and malaria; but the higher parts are comparatively healthy. Sierra Leone is often called the 'White Man's Grave;' but the title would be just as appropriate to any of the adjacent coast-regions of that part of Africa. The resources of the colony are by no means fully developed. Agriculture and trading employ each only about one-fifth of the population, which in 1890 numbered 75,000 individuals (60,546 in 1881; 37,039 in 1871). They are nearly all negroes, about one-half the descendants of liberated slaves, the others belonging to almost all the tribes of that part of Africa. But all the negroes are alike indolent, and the soil does not yield anything like what it is capable of yielding. Coffee, cocoa, tapioca, ginger, maize, cassava, and cotton are grown; but the bulk of the exports (ground-nuts, kola-nuts, benni-seed, ginger, hides, palm-oil and kernels, india-rubber, and gums) come from the interior. These commodities are exported to the annual average value of £332,600, of which Sierra Leone itself contributes but a very small part. Of the total value an average of £141,000 represents the exports to England. The import trade ranges between £248,000 (1886) and £390,000 (1890) a year, England's share falling between £190,500 (1888) and £295,000 (1890). Clothing, provisions, wine and spirits, iron and steel goods, haberdashery, gunpowder, and tobacco are the principal imports. *The harbours of the colony are entered* by 715 vessels of 250,000 tons every year. There is a little boat-building, mat-making, and cloth-weaving. The capital is Freetown (q.v.), now a fortified naval depôt and coaling station. The colony is provided with good roads, and has a frontier police of 290 men (organised in 1890), besides part of the West India regiment (400 men). Fouray Bay College (1828), near Freetown, belongs to the Church Missionary Society, and was affiliated in 1876 to Durham University. There are four or five good schools, a lunatic asylum (100 inmates), and a savings-bank (1120 depositors, holding £16,485 in 1890) in the colony. Sierra Leone gives title to an Anglican bishop, and contains many Methodists, besides a large body of Mohammedans. The governor is assisted by an executive council of five members, and the same officials together with three other persons nominated by the crown constitute the legislative council. In 1890 the revenue was £73,708, and the expenditure £63,056; the public debt was £58,454, the sinking fund for its redemption £27,831.

This district was discovered and named (from the lion-like thunder on its mountain-tops, Sierra Leone = Lion Mountain) by the Portuguese navigator, P. de Cintra, in 1462. In 1787 a body of freed slaves were planted here as a colony; but the enterprise was not a success. Four years later a second attempt was made by the Sierra Leone Company (which included amongst its promoters men like Granville Sharp, W. Wilberforce, and Sir R. Carr Glynn). But this scheme, even though supported by the arrival of 1200 freed negro slaves from North America, was not an unqualified success, and in 1807 the company transferred their rights to the crown. The boundaries of the colony have been gradually extended on all sides, except to the west, since 1862.

See T. R. Griffith, in *Proc. Roy. Colonial Institute* (1881-82); and Banbury, *Sierra Leone* (1888).

Sierra Madre ('Main Chain'), a general name for the mountains that in Mexico stretch northward from about Guadalajara to Arizona, forming the western wall of the plateau, and separating Chihuahua from the maritime states of Sinaloa and Sonora. Along the eastern foothills of the range, in north-west Chihuahua, the country is very fertile. The so-called Sierra Madre Plateau, on the United States frontier, is a northern continuation of the Chihuahua plateau.—The name has often been more widely extended, however, to include the central and eastern ranges of the Cordilleras.

Sierra Morena, a mountain-range, or rather a broad mountain-ridge in the south of Spain, forming the southern edge of the great central plain of the peninsula. It separates the basin of the Guadiana on the north from that of the Guadalquivir on the south, and ranges in height from 2000 to 5500 feet. Valuable mines of lead, silver, quicksilver, sulphur, and lignite, as at Tharsis and Rio Tinto, occur in certain parts of the system. It is frequently mentioned in *Don Quixote*, and is the scene of many of the incidents therein described.

Sierra Nevada (i.e. 'Snowy Range'), (1) a mountain-range of southern Spain, stretches east through the province of Granada to the frontiers of Almeria, is 60 miles in length, from 20 to 30 in breadth, and covers an area of 1060 sq. m. It forms a portion of the watershed between the streams that flow into the Mediterranean and those that flow into the Atlantic. The peak of Mulhacen (11,660 feet) is the highest point of the Spanish Peninsula. The range receives its name from the perpetual snow which covers the highest summits (down to 11.000 feet). The system is connected with other mountain-masses in Spain, to north, east, and west, and its edges are much indented by deep valleys.—(2) A range of mountains in California, forming the eastern boundary of its Great Central Valley, and extending from north-west to south-east 450 miles, until in the neighbourhood of 35° N. this and the Coast Range meet and become continuous. Among the higher peaks of the Sierra Nevada are Mount Whitney (14,886 feet high), Mount Shasta (14,440), Mount Tyndall (14,386). Granite and metamorphic slate are the principal rocks; in some parts volcanic rocks are abundant. The sides of the range are covered with great forests, gold imbedded in quartz is found in large quantities, and silver-mines have been opened on the east side. The Southern Pacific Railroad crosses the range at an altitude of 7042 feet.—(3) *Sierra Nevada de Mérida* is the principal chain of the Andes in Venezuela, rising to over 15,300 feet.—(4) *Sierra Nevada de Santa Marta* is a system in the north of the department of Magdalena, in Colombia, flanking the sea, and stretching westward from near Venezuela to the low swamps and marshes of the Rio Magdalena (about 120 miles). The central knot consists of two tables, with from eight to ten separate summits, all capped with snow, the highest point variously estimated at from 16,400 (Sievers) to 17,500 (Simons) feet. The leading rocks are granite, syenite, and various slates, sandstones, quartz, and older eruptive rocks. The northern slopes are densely wooded with virgin tropical forests from 4000 feet downwards; the southern slopes are naked rocks above 6300 feet. The valley of the Rio Cesar is especially fertile, and in the mountains the Arhuacos Indians have even coca plantations. Copper, silver, and gold are found, and coal in the Rio Cesar valley. Much difference of opinion has existed as to whether this group is an independent system or connected with the Andes. Dr Sievers avers that they unite a little to the south of 11° N. lat. in the Sierra de Perijá, within a triangle formed by the towns of Fonseca, Treinta, and Soldado. See his *Reise in der Sierra N. de S.M.* (Leip. 1887); also a paper in *Proc. Roy. Geog. Soc.* (1881) by F. A. A. Simons, and another in *Scot. Geog. Mag.* (1887).

Sieyès, EMMANUEL JOSEPH, COMTE, who, as the Abbé Sieyès, figures prominently in the French Revolution, was born, the fifth child of an honest bourgeois family, at Fréjus, May 3, 1748. He had his education from the Jesuits at Fréjus and the Doctrinaire Fathers at Draguignan, and first wished to be a military engineer, but was condemned to the clerical calling by the weakness of his health. He studied theology at Saint Sulpice, where his originality and boldness of speculation caused no small misgiving to his masters, and completed his course at the seminary of Saint-Firmin He became canon in the diocese of Tréguier (1775), next chancellor and vicar-general of the diocese of Chartres, and was sent by the latter to the Chambre Supérieure of the Clergy of France. Between the dissolution of the Assembly of Notables and the reunion of the Constituent Assembly he published three famous pamphlets which carried his name over the length and breadth of France: *Vues sur les Moyens d'Exécution* (1788), *Essai sur les Privilèges* (1788), and, the most famous of all, *Qu'est-ce que le Tiers-État?* (January 1789). His answer to the last question was 'Everything;' 'What has it been hitherto?' was his next question; its answer, 'Nothing.' 'What does it desire to be?'—'Something.' He was elected one of the deputies for Paris, and it was on his motion (June 10, 1789) that the tiers-état sent a final invitation to the noblesse and clergy to join them, with the intimation that if they refused they would constitute themselves into the States-general. Seven days later the National Assembly was formed, the name being due to the suggestion of Sieyès. After Mirabeau made his memorable answer to the king's messenger, the Marquis de Dreux-Brézé (June 23), Sieyès reassured the members with the characteristically quiet words, 'Gentlemen, you are to-day what you were yesterday.' The deadly enemy of privilege, cold, inflexible, fearless in logic and trenchant in phrase, Sieyès gained great influence, and the division of France into departments for administrative purposes, declared in the last two months of 1789, was mainly his work. He took part in the memorable declaration of the Rights of Man (August 26, 1789), and opposed the royal veto, during the great debate on which question Mirabeau invoked the counsel of Sieyès as that of a man 'whose silence and inaction I regard as a public calamity.' But he kept aloof from Mirabeau's alliance, opposing his policy alike in the last measure and in his refusal to the Assembly of the right of nominating the Regent in the event of the king's death. He was elected to the Legislative Assembly, sat in the centre, voted for the king's death *sans phrase* (though he afterwards denied adding these words to the one word *mort*); but as the Revolution grew sank into 'philosophic silence,' his heart filled with disdain alike at its illogical excesses and the bombastic rhetoric of its leaders. Asked long afterwards what he had done during the Terror, he is said to have replied, 'J'ai vécu.' He opposed the new constitution of Year III. (1795), and declined a seat on the Directory named by the new Corps Législatif, which entered on its functions on the 27th October of that year, but had a share in the *coup d'état* of 3d September 1797 (17th Fructidor). In 1798 he went on mission to Berlin, was elected to the Directory in 1799, and now, like Barras a traitor to the Republic, he plunged into a web of dark intrigues with a view to find a soldier who would be content to be an instrument. Bonaparte returned from Egypt on October 25, 1799, and together they plotted the revolution of the 18th Brumaire (November 9, 1799), the result of which was the institution of the Consulate of Sieyès, Bonaparte, and Roger Ducos. Once more he drew upon his skill as a framer of constitutions, his final effort being a masterpiece of complexity beyond the calculating machine of Pascal, its aim to break the force of democracy by dividing it, to triumph over the passions of men by cunningly balancing them the one against the other. But he soon discovered in his new ally a master. Finding himself befooled by Bonaparte, he threw up his consulship in disgust, his last illusion shattered for ever. His fall was somewhat gilded over by the title of Count, a sum of 600,000 francs, and the estate of Crosne. The presidency of the senate was offered him later, but declined. He wrapped himself in morose meditations during the Empire, filled with silent irony and scorn for that humanity which had so little realised his views. Exiled at the Restoration, he lived in Belgium for fifteen years, returned in 1830, and after a long illness in which his mind often wandered to the Terror and the sinister name of Robespierre, died at Paris, June 20, 1836.

The influence of Sieyès upon the Revolution is clear enough, but the man remains wrapped in shadow. He was reserved and solitary from his youth, but we may write over against this that he was passionately fond of music, and that a woman once said of him, 'Quel dommage qu'un homme si aimable ait voulu être profond!' He believed absolutely in the infallibility of his own abstractions: 'Polity is a science I have completed,' he said to Dumont. Rigorous in everything—in nothing more than in the closeness of the bond between logic and language—he would have reduced to a merciless and inflexible system every aspiration of mankind. But he revealed a fundamental want of insight into the nature of man in thinking that masses of men could ever be governed by bare reason alone. For human nature remains much more complex than the subtlest calculations, the factors in the process obscure, the conclusion still uncertain. Sieyès was himself a creature all head, to the complete exclusion of heart, exactly what he wanted his human puppets to be, and the end of all his scheming was discomfiture and a name in history to inspire respect, not sympathy.

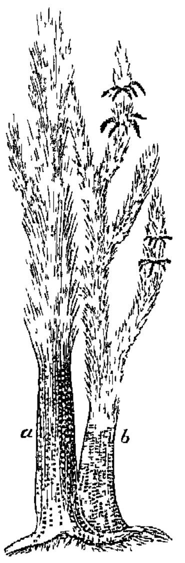
Sigillaria (Lat. *sigillum*, 'a seal'), a family of fossil plants, which ranges from the Devonian to the Permian system, but is more especially abundant in Carboniferous strata. The plants had slender, pillar-like trunks, some of which attained a diameter of 5 feet and were proportionately tall, reaching a height of 50 to 70 feet. Towards the top they branched dichotomously several times. The columnar stems are ribbed and fluted longitudinally in a very regular manner, the flutings being marked by rows or whorls of scars left by fallen leaves. The form of these seal-like scars is very variable, but they are all so arranged that the scars of each horizontal row are placed in the intervals between the scars of the rows immediately above and below. The thick dichotomous branches of the tree were clothed with long grass-like leaves. The fruit is still unknown, some botanists supposing that Sigillaria had cones like those of lycopods, while others think it probable that the fruit resembled that of yew-trees. The structure of the stem is peculiar: the external rind or coat is hard, beneath that is a great thickness of cellular tissue traversed by rope-like bands of fibres forming an inner bark, while in the centre is a comparatively small firm woody axis. The roots usually start from the stem in four main branches, which divide dichotomously several times, and then extend for long distances like great cylindrical cables, which, Sir W. Dawson considers, were intended to anchor the tree firmly in soft and marshy ground. Cylindrical rootlets proceeded from these long cable-like roots in a regularly spiral manner, and when they decayed they left rounded scars. These roots were formerly supposed to be a distinct species till stems of Sigillaria were found with Stigmarian roots attached.

The stem of Sigillaria is not often so well preserved as to show any structure, or even its cylindrical form. It generally occurs as a double layer of coal exhibiting on the outer surfaces the scars produced by the bases of the leaf-stalks. Indeed from the fact that most coal-seams are underlaid by what appear to be old soils or underclays, which are crowded with roots, it would seem that Sigillariæ, and probably other trees with Stigmaria-roots, enter very largely into the formation of many coal-seams. Some of the more impure coals, which are interlaminated with shale, &c., consist principally of the flattened stems of Sigillaria mixed with the debris of other plants. From this and other evidence Sir W. Dawson is of opinion that the growth of a forest of Sigillariæ and other trees having Stigmaria-roots was the first step towards the accumulation of a bed of coal, and that the formation of this coal terminated as it had begun by a forest growth. This is shown by the fact that in some localities erect stumps of Sigillaria rise from the upper surfaces of the coal-seam, and penetrate the overlying shales and sandstones.



Sigillaria restored : *a*, *Sigillaria Brownii*; *b*, *S. elegans*. (After Dawson.)

Botanists are still undecided as to the position of Sigillaria. Some eighty species have been described from the Carboniferous system, and many more must have existed; and it is quite probable, as Sir W. Dawson thinks, that the group of Sigillariæ may eventually be divisible into several forms. He considers that some will come to be classed with the Lepidodendroids, while others will prove to be allied to the pines and cycads (Gymnospermeæ). See Dawson's *Geological History of Plants* (1888), and STIGMARIA.

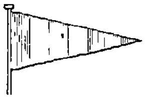
Sigismund, emperor of Germany (1411-37), the son of the Emperor Charles IV., was born on 14th February 1368. He was made king of Hungary when only nineteen, succeeding to that dignity through his wife. In 1396 at the head of a numerous army he attempted to relieve the Byzantine empire from the Turks, but was terribly defeated at Nicopolis (28th September). Some years later he conquered Bosnia and Herzegovina and reduced Servia to his sway. In 1411 he was proclaimed emperor on the death of Rupert. One of his earliest acts as emperor was to induce Pope John XXIII. to call together the *Council of Constance for the purpose* of putting an end to the Hussite and other schisms. But although he supported the party of reform, he made no effort to uphold the safe-conduct he had granted to Huss, and permitted him to be burned by his enemies. In return for this breach of faith his succession to the throne of Bohemia, after his brother's death, was opposed by the Hussites; and they maintained their opposition so stoutly that it was 1436 before Sigismund, making concessions, could put the crown of Bohemia on his head. But in the year following he died at Znaim, on 9th December. This emperor possessed many of the qualities of a capable ruler, and made praiseworthy attempts to introduce various reforms in the administration of the empire; but his efforts seem to have been frustrated in great part by his own lack of decision and by his chronic want of money.

See works by Aschbach (4 vols. Hamb. 1838-45), Bezold (Mun. 1875), Lenz (Berl. 1874), and Windecke (Ger. trans. Leip. 1886).—For the Polish Sigismunds, see POLAND.

Sigmaringen. See HOHENZOLLERN.

Signalling is the means of transmitting intelligence to a greater or less distance by the agency of sight or hearing. Incomparably the most powerful medium yet known for this purpose is the electric current (see TELEGRAPH, TELEPHONE). The electric current requires fixed or (as in the case of field telegraphy) travelling apparatus establishing an actual communication between the two points; and is therefore inapplicable to the ordinary cases of ships interchanging signals with each other or with the shore. For railway signals, see RAILWAYS, Vol. VIII. p. 558.

The ancients seem to have elaborated a fair system of night-signals by torches for military purposes (see BEACON); but in naval affairs the ships sailed so close together that orders could be communicated by word of mouth, while the turning of a shield from right to left sufficed as sailing directions to the several lines. In the time of James II. a ship's signal could only be expressed by flags, in confusing number, hung in different parts of the vessel.



'Code Signal' and 'Answering Pennant'

N.B.—When used as the 'Code Signal,' this Pennant is to be hoisted under the 'Ensign;' when used as the 'Answering Pennant,' where best seen.

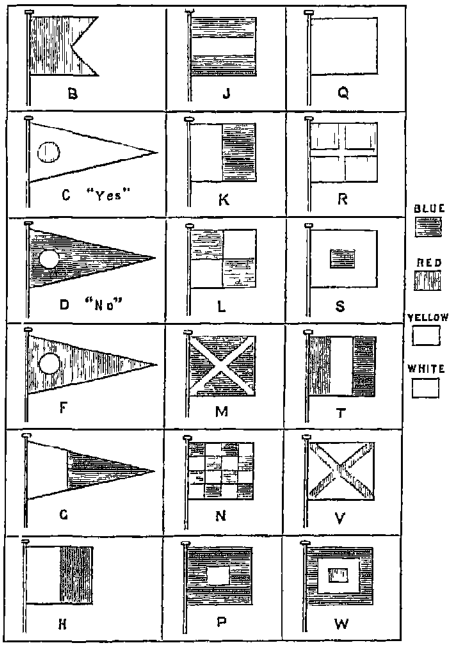


Fig. 1.—Flags of the International Code of Signals.

Thanks to Sir Home Popham, Marryat, and other inventors, the system has been adopted of hanging a number of flags under one another, each symbol or combination having an arbitrary conventional meaning attached to it. In consequence of action taken by the British Board of Trade, the system of sea-signals called the *International Code of Signals* was compiled in 1857 and adopted by nearly all the commercial nations of the world. Except for confidential signals, it is also used on board the ships of the British royal navy. The system consists of eighteen flags and a code pennant (see fig. 1).

In using and interpreting these signals it is of course necessary to be in possession of the signal code-book, in which the arbitrary meanings attached to the flags and combinations of the flags are printed, but the general nature of the meaning of a hoist can be determined by the form of the hoist. This is the case because the meanings of the hoists are arranged in the signal-book upon the following plan, viz.: (1) Signals made with two flags: If burgee (B) is uppermost, it is an attention signal; if a pennant (C, D, F, or G) is uppermost, it is a compass signal; if a square flag (H to W) is uppermost, it is an urgent or distress or danger signal. (2) Signals made with three flags: The meanings of these are not classified according to the top flag; they relate to general subjects of inquiry or communication. (3) Signals made with four flags: If burgee (B) is uppermost, it is a geographical signal; if one of the three pennants C, D, or F is uppermost, it is a spelling or vocabulary signal; if the pennant G or a square flag (H to W) is uppermost, it is the name of a man-of-war or merchant ship. All the two- and three-flag hoists, and also the four-flag geographical hoists, have the same meanings printed in the signal-book of the various nations which have adopted the code, each nation printing its own copy of the signal-book in its own language, and thus two ships, totally ignorant of each other's language, may converse by means of these flags.

'Preparative Answering'

And 'stop' after each complete Signal.

'Annul' Signal.

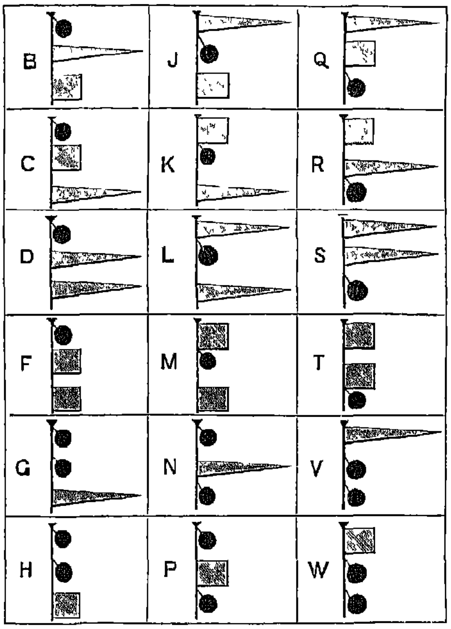

Fig. 2.—Distant Signals.

As signal-flags can only be used within distances across which their colours are distinct, the flag code has been supplemented by what are called distant signals. They are made by taking any two square flags, any two pennants, and two balls, and making the signals for the letters on the flag-plate by the combinations shown in fig. 2. The interpretations are made in the usual way by the aid of the signal-book.

Still further to increase the use of the code, a system of semaphore signals is also available in the same code, the ball of the distant signal being replaced by a level arm, the square flag by an arm pointing upwards, and the pennant by an arm pointing downwards. The semaphore alphabet is shown in fig. 3. These may also be used from boats or from a boat's crew on a beach by making three persons hold out something resembling a ball, pennant, and flag, and reading from left to right. A hat, a man's arm, and a square handkerchief do very well.

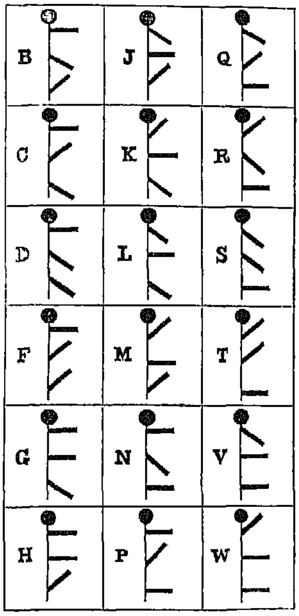

Fig. 3.—Semaphore Alphabet.

In this code the largest possible number of two-flag hoists is 306, of three-flag hoists 4896, and of four-flag hoists 73,440, giving a possible total of 78,642 different signals.

These signals are of use only during the day. The question of *Night-signalling* at sea is now engaging attention. In H.M. royal navy, where the use of the semaphore is far more common than in the merchant service, the electric light is utilised to make semaphore signals visible at night. The form of night-signalling which finds most favour is that of flashing lights. Several ingenious inventors have produced flashing lights visible at long distances. It is probable that signalling by long and short flashes, using the Morse code in connection therewith, will ultimately become common at sea, especially as the same code may be used along with long and short blasts on a steamer's whistle or other sound signal, and the signals so made could be interpreted either with or without the signal code-book at will.

The international signals used by vessels which are in *distress* and want assistance are: In the day-time, a gun fired at intervals of about a minute, or the flags NC, or a square flag having a ball above or below it; in the night-time, a gun fired at intervals of about a minute, or flames, as from a burning tar-barrel, oil-barrel, &c., or rockets or shells of any colour or description, fired one at a time at short intervals.

For the numerous signals to be made by the various classes of vessels at sea at night or in fog, &c., reference may be made to the *Regulations for Preventing Collisions at Sea*, issued in pursuance of the Merchant Shipping Amendment Act, 1862, and as altered in 1885. Briefly, these declare that at night a steamer shall show a white elevated light visible round twenty points of the compass, a starboard green light, and a port red light each visible ten points. A steamer towing doubles the white masthead light. A sailing-vessel is to show only the red and green side-lights. Trawlers and net and line fishers have special lights. A pilot-vessel shows a white fixed light and a flash-light. All vessels at anchor show a white light. Vessels being overtaken show a white stern light.

Vessels broken down show (vertically) three black balls in the day and three red lights at night. A telegraph ship shows three shapes—red, white, red—in the day (the reds globe-shaped, and the white diamond-shaped), and three lights—also red, white, red—at night. In fog, mist, and falling snow, both day and night, all vessels at anchor ring a bell; steamers going make long blasts on the steam-whistle; sailing-vessels going make one, two, or three long blasts on a fog-horn; and fishermen not at anchor sound the fog-horn and bell alternately; all at intervals not exceeding two minutes. A steamer turning its head to starboard, to port, or going full speed astern may indicate the same to a vessel in sight by making one, two, or three short blasts respectively on the steam-whistle. These are practically international signals.

A vessel *wanting a pilot* shows the flags PT, or the Jack (or other national colour) at the fore; or at night burns a blue light, or flashes a white light at short or frequent intervals for about a minute at a time.

The use of *signals to indicate* to the mariner or others *the approach of storms* has now become common in maritime countries. In Great Britain the probable approach of a gale from points from SE. round by *south* to NW. is indicated by a cone in the daytime, *point down*, and at night by three red lights in a triangle, point down; and the probable approach of a gale from NW. round by *north* to SE. is indicated by the cone or triangle of lights being hoisted *point up*. In France a drum in addition to the cones is hoisted when necessary to indicate greater force of wind. Besides these a flag, a short pennant (cornet), and a pennant of any colour mean respectively doubtful weather—barometer tending to fall, bad weather, and appearance of better weather in the open sea. In Germany a ball indicates caution; a cone point down, storm from SW.; cone point up, storm from NW.; two cones points down, storm from SE.; two cones points up, storm from NE. One square flag hoisted in addition indicates that the wind will probably change to the right hand, and two such flags that it will probably change to the left hand. In the Netherlands the Aeroklinoscope (invented by Buys-Ballot, q.v.) is used. It is simply a beam, half red, half white, with a ball suspended from the white arm, the whole being capable of rotation in both a horizontal and vertical plane. The arm is pointed horizontally in the direction of the two stations having the greatest difference of height of barometer readings, and the end of the beam pointing towards the place of the *highest* barometer reading is then tipped *up* in proportion to the difference of the barometer readings at the two stations in question.

In the United States a square red flag with a black centre indicates a violent storm; a yellow flag with a white centre, a light storm; a red pennant indicates that the storm trough is approaching the station, and a white pennant that the storm trough has passed the station. Further, if the red or white pennant is hoisted *above* the square flag, the station is probably on the *north* side of the centre of the storm; and if the red or white pennant is hoisted *below* the square flag, the station is probably on the *south* side of the centre of the storm. A yellow pennant means 'call at the station for special weather information.' At night a red light indicates easterly winds, and a white light above a red light westerly winds. This harmonises with the red flag (easterly) and the white flag (westerly) in the day-signals. The United States weather bureau has also recently arranged to hoist the following 'forecast' signals—viz. white flag for fair weather; blue flag for rain or snow; blue and white flag for local rains; triangular black flag above these for higher temperature, and below for lower temperature; and white flag with black square in the centre for cold waves or frosts.

Many local signals of different kinds are in use: e.g. at Mauritius a white flag with horizontal blue stripes below a ball means 'prepare for bad weather,' and a red flag below a ball means 'take lower yards and topmasts down.' In Mexico a red flag means 'a norther may be expected.' Some other countries have adopted the simple signals used in Britain; but it is to be regretted that a uniform system of storm-warning signals is not universally adopted.

The system of visual signalling adopted in the British army is a combination of short or long flashes by lamps at night, and the alternate appearance or obscuration of any given object by day (revolving shutters or discs, semaphores, collapsible cones, flags, or even jets of steam), and if visible symbols are not available, short and long sounds on a fog-horn, bugle, or steam-whistle may be used. By any of these means the dot and dash of the Morse alphabet, as used in telegraphy, can be expressed; but the regular method is to use flags or mirrors (the Heliograph, q.v.) if the sun is shining by day, and lamps at night. Every regiment and battalion trains a number of its officers and men each year in signalling, which has been found to be of the greatest use on active service, especially in savage countries. Not only messages but drawings have been sent by signal—using paper covered with numbered squares—e.g. the position of the Afghans on the Peiwar Khotal (1878) was in this way signalled back by the advanced parties. Fig. 4 shows the manner of working the flag: from *a* to *b* and back to *a* is a dot, from *a* to *c* and back to *a* is a dash. The code and numbers laid down in the army and navy signal-book are sometimes used instead of spelling the words by the Morse alphabet. This prevents unauthorised persons reading the signals.—For Lloyd's Signal Stations, see LLOYD'S.

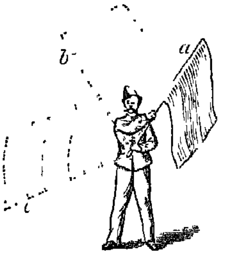

Fig. 4

Signature. See BOOK, Vol. II. p. 300. For signing, sealing, and delivering, see DEED.

Signatures, THE DOCTRINE OF, an inveterate belief in early medicine that plants and minerals bore certain symbolical marks which indicated the diseases for which nature had intended them as special remedies. These figures, of course, were not the result of chance, but the evidence of Providence, being really the characters and figures of those stars by whom they are principally governed and endowed with particular virtues. And the doctrine brings us into the wider region of magic in its fundamental confusion between an object and its image, the word and its idea. Many names witness to a belief in this theory, as *mandrake*, *kidneywort*, *scorpion-grass*, and the *Euphrasia* or eyebright. In the case of the last, for example, the plant was supposed to be good for the eyes, because of a black pupil-like spot in its corolla; and by an analogous process of thought the yellow turmeric was thought good for jaundice, the bloodstone for stopping bleeding. Similarly white things were regarded as refrigerant, red as hot. So in small-pox red bed-coverings were used, with the view of bringing the pustules to the surface of the body; red things were to be looked upon by the patient; burnt purple, pomegranate seeds, mulberries, and other red ingredients were dissolved in his drink. John of Gaddesden, physician to Edward II., directs his patients to be wrapped up in scarlet dresses, and claims by this means to have recovered the young prince quickly from an attack of small-pox. Wraxall, in his *Memoirs*, tells us that this was done so late as 1765 with the Emperor Francis I. when ill with smallpox. See PLANTS, Vol. VIII. p. 222; and T. J. Pettigrew, *On Superstitions connected with Medicine and Surgery* (1844).

Signboards were known to both Greeks and Romans. There are allusions to them in classic writers; and specimens have been found at Pompeii and Herculaneum, sometimes painted, but oftener carved. A bush was the sign of many taverns so latè as the reign of James I., and the antiquity of that sign may be inferred from the analogy of our proverb, 'Good wine needs no bush,' to the Latin 'Vino vendibili suspensâ hederâ non opus est.' During the illiterate middle ages every trade had its emblem, some of which have survived to our day, as the chemist's pestle and mortar, the pawnbroker's three balls, and the barber's pole, with in Scotland (as on the Continent) the brazen basin, which recalls Don Quixote. Besides these trade emblems, every individual trader might have his own special device: Southey's father, a Bristol linen-draper, for his chose a hare. The old printers' emblems, described in Vol. II. p. 303, were akin hereto, as to-day are trade marks. During the 16th and 17th centuries huge painted signs came greatly into vogue. They were suspended either from projecting metal-work, from a post or an obelisk, or from a sort of miniature triumphal archway, and sometimes cost great sums—e.g. £1057 for the 'White Hart' at Scole in Norfolk, erected in 1655. These creaking and ponderous signboards proved a source of annoyance, sometimes of positive danger, as when in 1718 one in Bride's Lane, Fleet Street, dragged down a house front, and killed in its fall four persons. So in 1762–70, under act of parliament, the London signboards were either wholly removed or at least affixed to the fronts of the houses; and this example was gradually followed throughout the kingdom, though here and there signposts linger, or have been restored—even in London. One of the oldest and most interesting signs still existing is the 'Red Lion' at Martlesham, Suffolk, for it was the figurehead of one of the Dutch fleet defeated off Southwold in 1672; but the history even of vanished signboards has no slight interest. A good many signboards have been painted by great artists, Holbein, Correggio, Paul Potter, Hogarth, Wilson, Morland, David Cox, 'Old' Crome, Sam Bough, and Sir J. E. Millais (some of which are still extant); and nearly every sign had its curious origin, hard though it may be to come at. Thus, there were the religious signs ('Salutation,' 'Lamb and Flag,' &c.), historical signs (as the 'Royal Oak' and 'Marquis of Granby'), heraldic (coats of arms, crests, and badges), humorous (as the 'Good Woman,' without a head), and a host of others. Not the least curious feature about old signs is the havoc played on them by 'folk-etymologies,' which have, for instance, corrupted the 'Bacchanals' into 'Bag o' nails,' 'Boulogne Mouth' (i.e. the entrance to Boulogne harbour) into 'Bull and Mouth,' the 'Catherine Wheel' into 'Cat and Wheel,' and, more dubiously, 'Caton fidèle' (a faithful governor of Calais) into 'Cat and Fiddle,' 'God encompasseth' into 'Goat and Compasses,' and 'Piga wassail' (A.S., 'Virgin, hail,' or 'a lass and a glass') into 'Pig and Whistle.'

See Larwood and Hotten's *History of Signboards* (1866), Miller-Christy's *Trade-signs of Essex* (1887), and F. G. H. Price's *Signs of Old Lombard Street* (1887).

Signet, in England, one of the seals for the authentication of royal grants; for its use and for the signet office, now abolished, see SEAL, p. 277. The signet in Scotland is a seal which seems to have been originally intended to authenticate royal warrants connected with the administration of justice. The principal class of solicitors in Scotland are called Writers to the Signet, from their having been originally clerks in the office of the king's secretary, it being their duty to prepare all warrants for charters or grants to be passed under either the Great Seal or Privy-seal, such warrants being called from an early period 'signatures,' because they bore the signet of the king. Writers to the Signet and Solicitors before the Supreme Courts were long the only solicitors allowed to act as agents in the Supreme Courts. But by the Law Agents Act of 1873 any person duly admitted a law agent can practise in any court in Scotland. See SOLICITORS.

Sign-manual, ROYAL, the superscription of the sovereign, which must be adhibited to all writs which have to pass the Privy-seal or Great Seal. When attached to a grant or warrant it must be countersigned by one of the principal secretaries of state, or by the Lords of the Treasury. For certain deeds of minor importance a *cachet* or stamp of the royal signature is used.

Signorelli, LUCA, Italian painter, was born about 1441, at Cortona, being a distant relative of Vasari, the historian of Italian art. He studied under Piero della Francesca of the Umbrian school, but seems to have learned most from observation of the human form. During the first half of his life he had apparently no settled home; at all events he worked in various towns in Italy. At Loretto he painted a number of frescoes of sacred subjects, commissioned by Pope Sixtus IV.; in the Sistine Chapel the fresco called the Acts of Moses; and for Lorenzo de' Medici the picture known as the School of Pan. This last design he subsequently repeated on the wall of Pandolfo Petrucci's palace at Sienna; in a convent of that same city he painted, after 1497, eight frescoes illustrating the Life of St Benedict. But the greatest achievement associated with his name is a number of frescoes, depicting such subjects as the Fall of Antichrist, Punishment of the Wicked, the Last Days of Earth, done on the walls of a chapel of the cathedral in Orvieto. The boldness and grandeur of invention shown in these designs, and the powerful modelling of the nude forms, suggest comparisons with Michelangelo. Signorelli was one of the painters summoned to Rome by Pope Julius II. in 1508 to adorn the Vatican, and along with his colleagues was dismissed to make way for Raphael. In his native town he left many proofs of his artistic skill, and died there in 1523.

See Crowe and Cavalcaselle's *History of Painting in Italy* (1864–71), Sidney Colvin in the *Cornhill* for 1875, and R. Vischer's *Luca Signorelli* (Leip. 1879).

Sigourney, MRS LYDIA HUNTLEY (Huntley being her maiden name), American authoress, was born at Norwich, Connecticut, 1st September 1791. For five years she taught a class of ladies in Hartford; in 1815 she published *Moral Pieces in Prose and Verse*; and in 1819 she married a Hartford merchant. In 1822 she published a descriptive poem on the *Traits of the Aborigines of America*; and in 1824 a *Sketch of Connecticut Forty Years Since*. These were followed by *Pocahontas and other Poems*, *Lays of the Heart*, *Tales in Prose and Verse*, &c., and *Letters to Young Ladies* and *to Mothers*, both of which passed through many editions, in England as well as America. In 1840 she visited Europe, and on her return wrote her *Pleasant Memories of Pleasant Lands*. She compiled amusing and instructive books for the young, and was a constant contributor to magazines and other periodicals of poems, whose subjects, style, and sentiment gave her the designation of 'the American Hemans.' She died at Hartford, 10th June 1865. See her autobiographical *Letters of Life* (New York, 1866).

Sihûn. See JAXARTES.

Sikhs, a religious sect of Northern India, which became a great military confederacy. The sect was founded by Baba Nának (born in 1469), who rejected the institution of caste, idolatry, and superstition, preached the existence of One spiritual God, and inculcated a higher moral life. He was followed in the headship of the sect—'Sikhs' means 'followers' or 'disciples'—by ten 'gurus' or chief-priests. The third of these excavated the sacred tank at Amritsar; and his son, Arjun Mal, built, towards the end of the 16th century, the holy temple, in the tank at Amritsar, which became the headquarters of the Sikh religion. The same guru first edited the *Adi Granth*, the sacred book of the Sikhs. As time went on the adherents of the sect, principally Jats by race, gradually becoming conscious of their numbers and their growing power, began to adopt something of a military organisation in addition to their religious discipline. This end—converting them into a powerful military community—was deliberately pursued by the guru Govind Rai (1675–1708); he adopted the appellative Singh (or Sing; better Sinh, 'lion') as a generic family-name for all members of the sect, strengthened the bonds of personal discipline, and revised the sacred book so as to bring it into harmony with the altered aims and position of the Sikhs. See INDIA, Vol. VI. p. 107.

On the downfall of the Mogul power, shortly after the middle of the 18th century, the Sikhs formed themselves into a number of tribal and territorial confederacies, some of which were virtually independent states. Their religious fanaticism was fanned by a body of devotees, who dedicated themselves to warlike pursuits; and the Sikhs greatly extended their possessions. It was, however, Ranjit Singh (q.v.), a young and warlike chieftain, who converted the Sikh confederacies into a powerful and formidable military power, by welding the separate confederacies into one organic whole and carrying his arms westwards, northwards, and southwards. On the east alone he made no conquests; he had in 1809 concluded a treaty of peace with the British, whose authority reached to the Sutlej, which was the eastern boundary of the Sikh dominions. This agreement Ranjit faithfully kept; but at his death he left an army of 124,000 men, animated by a warlike spirit and inspired by religious enthusiasm—a force that had been thoroughly organised and drilled by French officers on the European system. But there was none amongst his immediate descendants capable of taking up the sceptre he let fall, and wielding it with the same energy and skill. Amid the anarchy that followed his death, the soldiers of his armies clamoured to be led against the forces of the British; and accordingly in December 1845 they crossed the Sutlej and invaded British territory. Their advance guard was, however, routed by Sir Hugh Gough at Mudki (18th December), though not without heavy loss to the British, 'Fighting Bob' Sale being amongst the slain. The main body entrenched themselves at Firozshah, 12 miles east of the river; but their camp was stormed, after two days' desperate fighting, by Sir Hugh Gough and Sir Henry Hardinge (governor-general) on December 21st and 22d. Another Sikh army that crossed the river was defeated and driven back by Sir Harry Smith, at Aliwal (28th January 1846); and on 10th February Gough and Hardinge totally crushed and dispersed the Sikh forces at Sobraon. The British at once captured Lahore, and on the 9th March following peace was signed between the combatant parties, the Sikhs ceding the districts between the rivers Sutlej and Ravi, and subsequently, in lieu of a money indemnity, Cashmere, the hill-country of Hazara, and some other portions of territory.

Two years later war broke out again, caused, as the first conflict was, by Sikh fanaticism: two British officers were massacred at Multan in April 1848. And although Lieutenant Herbert Edwardes attempted to check the movement at its beginning, the war became general. Multan was taken; but the battle of Chillianwala (13th January 1849) was left undecided, in spite of very heavy losses on the British side. At Gujrat, however, on 21st February, Gough finally crushed the Sikhs and effectually broke their power. After this the Punjab was annexed to British India. And so successfully was its government organised and administered by Lord Dalhousie and John and Henry Lawrence that on the outbreak of the Mutiny the Sikhs not only refrained from joining the rebel sepoys, but lent very material assistance in quelling that formidable outbreak. The Sikhs still constitute about 6 per cent. of the population of the Punjab; and there are connected with the Punjab government fifteen protected Sikh states, of which Patiala is the principal. In 1891 the Sikhs numbered 1,907,836.

See J. D. Cunningham, *History of the Sikhs* (1849); Sir J. Malcolm, *Sketch of the Sikhs* (1812); and Trumpp, *The Adi Granth or Holy Scriptures of the Sikhs* (Lond. 1877), and *Die Religion der Sikhs* (Leip. 1881).

Si-kiang, a river in the south of China, rises in the province of Yunnan, and flows almost due east, till just before Canton it turns south and pours its waters into the Chinese Sea. Canton and Hong-kong stand on the eastern arm of its delta, and Macao on the promontory that divides it from this arm, the Canton River.

Sikkim, a protected state in the north-east of India, bounded on the N. by Tibet, on the W. by Nepal, and on the SE. by Bhotan. Area, 1550 sq. m.; pop. 7000. The state lies on the southern slopes of the Himalayas, has mountains reaching to 24,000 feet and mountain-passes as high as 16,000 feet. Numerous swift torrents flow at the bottom of precipitous ravines. The valleys and lower slopes of the mountains are clothed with forest. The raja, who resides at the village of Tumlong, ceded Darjeeling to the British in 1835, having already acknowledged their 'protection' in 1816. The trade between Sikkim and Darjeeling decreased from £94,400 in 1877 to £3300 in 1884. In 1888 the erection of a fort under Tibetan influence led to a successful British expedition against Sikkim.—The district of Darjeeling (q.v.), which borders on Sikkim state, is often called British Sikkim.

Sikrol, or SECROLE. See BENARES.

Silage is the term applied to fodder which has been preserved by the process of Ensilage. Ensilage is a French word, tracing through the Spanish, from the Lat. *sirus*, Gr. *siros*, 'a pit,' whence the Spanish verb *ensilar*, 'to store grain in a *silo* or pit.' It was originally employed to denote the preservation of green forage in an air and water tight silo—the contents being tightly pressed down so as to get rid of and permanently exclude the oxygen of the air, and thereby prevent putrefactive fermentation. The practice, since its introduction into the British Isles, has been considerably extended, so that the term silage is now applied to fodder which has been preserved by pressure in stacks as well as to that preserved in silos by pressure. The practice of ensilage is of great antiquity. From time immemorial grain has been stored in underground pits in eastern countries. In the time of Pliny it was, he tells us, pursued with success in Thrace, Cappadocia, Barbary, and Spain. Varro also speaks approvingly of the process, and asserts that by it wheat could be preserved fresh for fifty years and millet for a century. In early times it was probably employed chiefly to hide stores of grain from invaders. It is now used mainly in the preserving of green food for cattle and horses. The converting of green fodder, as distinguished from ripened grain, into silage is believed to have been first practised in Germany. In 1843, in the *Transactions of the Highland and Agricultural Society of Scotland*, Professor Johnston gave a detailed description of the German system of making 'sour hay.' The practice spread through the Austro-Hungarian empire, where graves or trenches, 4 feet by 6 or 8 feet in breadth and depth, were dug and crammed with green grass or green Indian corn, the whole being covered over with a foot of earth. The distinction of first succeeding in directing general attention to the subject was earned by a Frenchman, M. Goffart, whose book, *Manuel de la Culture et de l'Ensilage des Maïs et autres Fourages verts*, published in 1877, was not only widely read in his own country, but was translated into English and published in New York in 1879. The method had already been tried to a small extent in America, and the perusal of M. Goffart's work aroused the deepest interest and led to numerous and extensive experiments. The general results were satisfactory, and soon the system found its way into Great Britain. Although several trials were made earlier, the systematic and extensive adoption of ensilage in the United Kingdom dates from 1882. In that year the successful experience of Vicomte Arthur de Chezelles, who had been pursuing the system upon a large scale in France, was made known through the press to British farmers. A host of experimentalists were instantly at work, and so keenly was public attention aroused that in 1883 the Ensilage Commission, a private but highly influential body, was formed to collect evidence and consider and make known the merits of the practice. A mass of valuable information was collected and was embodied in the official blue-books issued by the government.

The commission reported strongly in favour of the system, concluding as follows: 'After summing up the mass of evidence which has reached us, we can without hesitation affirm that it has been abundantly and conclusively proved to our satisfaction that this system of preserving green fodder crops promises great advantage to the practical farmer, and, if carried out with a reasonable amount of care and efficiency, should not only provide him with the means of insuring himself to a great extent against unfavourable seasons, and of materially improving the quantity and quality of his dairy produce, but should also enable him to increase appreciably the number of live-stock that can be profitably kept upon any given acreage, whether of pasture or arable land, and proportionately the amount of manure available to fertilise it.' From 1883 the progress of the movement in Great Britain was rapid. The British agricultural returns first included statistics as to ensilage in 1884. In that year 610 silos were reported as existing in Great Britain. In the next three years the number increased to 2694. By 1887 it was proved by repeated experiments in England that silage might be made in stacks as well as in silos, and, as would be expected, the discovery of the fact that the advantages of ensilage could be attained without incurring the cost of constructing a silo gave a great stimulus to the movement. It is found in practice that the percentage of loss by the spoiling of the food is rather greater in the stack than in the silo, but the balance of advantages is in favour of the stack, which has therefore gained the lead in popularity. Silos are in almost all conceivable forms, some specially constructed at great expense, others 'converted' from existing buildings at small outlay. The cost of construction has varied so much as from 8s. to 50s. per ton capacity. The methods of pressure employed consist of dead weights or of mechanical appliances. The latter, being more convenient in application, are now most largely used. Many ingenious contrivances have been tried for pressing silage. One of the most popular methods is by jacks, screw, and hydraulic. Several systems of pressure which have been patented are found to work admirably, both in silos and stacks. Two varieties of silage are made, the one 'sweet,' the other 'sour.' Originally all the silage made was of the latter kind. In 1884 Mr George Fry, of Chobham, England, made known the results of experiments by which he proved that 'sweet' or 'sour' silage might be produced at the will of the farmer. Prior to 1884 it was the universal custom to apply pressure as soon as the silo was filled. The product of that method was invariably 'sour' silage. Mr Fry filled his silo without packing the material, and deferred applying pressure for two or three days, until the temperature of the silage rose to about 120° to 140° F., when pressure was applied and the top of the silo covered. The theory advanced and proved by Mr Fry is that this temperature is sufficiently high to kill the bacteria which produce acid fermentation, and that, with the bacteria killed and the silage then weighted and the silo covered, the mass of green fodder will remain sweet and be practically preserved under the same conditions as fruits, vegetables, or meats are preserved when tinned. This process of making 'sweet' silage has been found peculiarly suited for stack ensilage, and, as 'sweet' silage is on the whole preferable to 'sour,' the method originated by Mr Fry has been extensively adopted. Temperature is the principal agent in the making of silage. This is controlled by pressure, and in the mass of silage it is measured by the stack thermometer, which should always be employed in silage-making. It is found a safe practice to allow the temperature of the mass to rise to from 130° to 140° F. before applying pressure if sweet silage is desired. Nearly all kinds of farm crops, except roots, may be preserved by the process of ensilage. The crops most largely converted into silage are meadow-grass, clover, rye-grass, lucerne, sainfoin, vetches, maize, and the cereal crops. In some cases the fodder is cut with the chaff-cutter before being put into the silo or stack, but the rule is, except with maize, to preserve it in its natural length. Nearly all kinds of farm stock eat both 'sour' and 'sweet' silage with relish, and it is the prevailing experience that by the process of ensilage the feeding value of the fodder is as a rule slightly enhanced. In wet climates the system is of great importance, for it practically renders the farmer independent of the weather in saving his fodder crops.

In the United States the subject was discussed by the agricultural journals as early as 1873–74; the French method was fully described in 1875 in the Report of the Agricultural Department; experimental silos were being made about the same date; but the first person who made silos and ensilage on a large scale was Francis Morris in Maryland in 1877. The system rapidly spread, especially in the eastern and middle states.

Silbury Hill. See AVEBURY.

Silchester, a village in the extreme north of Hampshire, 7 miles N. of Basingstoke, famous for the remains of the ancient Romano-British town of *Caer Segeint*, called by the Romans *Calleva*, and by the West Saxons *Silceastre*. The chief visible remains are the amphitheatre, 50 yards by 40, and the walls, 2760 yards in length; excavations have shown the foundations of a basilica, the forum, a temple, baths, &c.; and coins, seals, rings, and much broken pottery have been found. New excavations were begun in June 1890. See *The History and Antiquities of Silchester* (1821), and the work on Silchester by Plummer (1879).

Silené, a genus of plants of the natural order Caryophyllaceæ, having the calyx, corolla, and stamens of Lychnis (q.v.), three styles and a three-celled capsule opening at the top in six teeth or valves. The species are numerous, mostly natives of the temperate parts of the northern hemisphere, annual and perennial plants; nine or ten of them natives of Britain, and others frequent in flower-gardens. One of the most common British species is the Bladder Campion (*S. inflata*), a perennial, which grows in cornfields and dry pastures, and near the seashore, has a branched stem fully a foot high, ovate-lanceolate bluish-green leaves, panicles of white flowers, and an inflated calyx, with a beautiful network of veins. The young shoots are sometimes used like asparagus, and have a peculiar but agreeable flavour, somewhat resembling that of peas. They are best when most blanched. The cultivation of this plant was long ago strongly recommended, but it has not obtained a place among garden plants. The Moss Campion (*S. acaulis*) is a pretty little plant, with beautiful purple flowers growing in patches so as to form a kind of turf, one of the finest ornaments of the higher mountains of Scotland, and found also in Cumberland and Wales. Many species, some of them British, are popularly called Catchfly, from their viscidity, as *S. anglica*, a species found in sandy and gravelly fields in many parts of Britain. For the Red Campion, White Campion, and German Catchfly, see LYCHNIS.

Silenus, a primitive woodland deity of Asia Minor, whom men try to catch when in a drunken sleep, in order to compel him to prophesy and sing. Later representations make him a son of Hermes or of Pan, and the chief of the Sileni or older Satyrs, and the inseparable companion and instructor of Dionysus, with whom he took part in the contest against the Gigantes, slaying Enceladus. He is described as a little pot-bellied old man, bald-headed and snub-nosed, his body very hairy, always drunk and bearing a skin of wine, and usually propped up by the other satyrs or astride of an ass, since his own legs could not be trusted.

Silesia, a province of Prussia, lying in the extreme south-east corner of the kingdom, and having Brandenburg and Posen on the N., the Polish provinces of Russia and Austria on the E., and Austrian Silesia, Bohemia, and the kingdom of Saxony on the S. Area, 15,557 sq. m.; pop. (1875) 3,863,699; (1890) 4,223,807, including more than 820,000 Poles, some 55,000 Bohemians (Czechs), and 32,000 Wends. By religion more than one-half are Roman Catholics and somewhat less than two millions Evangelical Protestants. The province is drained almost entirely by the Oder (navigable from Ratibor), which traverses it from south-east to north-west; this river forms in the middle part of its course a deep valley, and this valley has a westward extension from near Liegnitz. The south-western parts are broken and made uneven by the Sudetic Mountains and their outlying ranges. On the northern and eastern sides of the Oder and in the west of the province there are extensive tracts of a marshy and a sandy character, on which large forests grow (29 per cent. of the total area). But between the Oder and the Sudetic Mountains the soil is exceptionally fertile, producing the usual cereals, besides flax, beet-root, chicory, hops, oil-plants, and orchard fruit. There are several very large estates in the province, the owners of which have done much to encourage the breeding of sheep, horses, and cattle. Silesia embraces in its south-eastern extremity one of the most productive coal-mining regions of Prussia (530 sq. m. in extent; annual output 16 million tons, valued at nearly 7 millions sterling). Zinc is also extracted to the annual value of £354,000, and lead of £365,000. In point of industrial activity Silesia ranks high amongst the provinces of Prussia; more than 35 per cent. of the population find employment in industrial pursuits. The most important departments are in linen and cotton; next in order of importance come the metal industries and the manufacture of cloth and woollens, beet-root sugar, glass, tobacco, and a great variety of other articles. The commerce is greatly hampered by the near proximity of the Russian frontier and its vexatious tariff regulations. Breslau, the capital, is the seat of a university, and gives title to a prince-bishop of the Roman Catholic Church.

Early in the 10th century Silesia, except the extreme western districts, was under the dominion of Poland, and towards the end of the 12th century was divided into two duchies (Breslau or Lower Silesia and Ratibor or Upper Silesia) ruled by Polish dynasties. In the following century great numbers of German immigrants settled in the country and gradually Germanised its semi-Slavic inhabitants. Duke Henry II. of Lower Silesia perished in the memorable battle of Liegnitz (1241), in conflict with the Mongol invaders. By the beginning of the 14th century Silesia was divided up amongst a score of petty rulers, nearly all of whom acknowledged King John of Bohemia as their feudal superior instead of the king of Poland in the years 1327–29. The Silesian dukes put no obstacles, as a rule, in the way of the Reformation; but the emperors, who as the heirs to the kingdom of Bohemia became the suzerains of Silesia, treated the people with cruel intolerance, and pursued that policy down to the first decade of the 18th century. The great duel between Austria and Prussia for the mastership of the Silesian territories grew out of a contract by which in 1537 the Duke of Liegnitz left his lands to the Elector of Brandenburg in the eventuality of his house becoming extinct in the male line. On the conclusion of the first Silesian war (1742) the duchies were divided pretty much in the way they are at the present time, Prussia getting by far the greater number and greater area; and the result of the second Silesian war and the desperate struggle of the Seven Years' War confirmed Frederick the Great in the possession of the lands he had so greatly coveted. Frederick, however, took the most active and judicious measures to improve his conquest, and reform its administration and put it on a sound basis. Silesia took a very zealous part in the final struggle against Napoleon in the early years of the 19th century. For the

Silesian Schools of Literature, see GERMANY (Vol. V. p. 187), and OPITZ.

See Grunhagen's *Geschichte Schlesiens* (2 vols. Gotha, 1884–86); Adamy's *Schlesien nach seinen physikalischen, topographischen, und statistischen Verhaltnissen* (6th ed. Breslau, 1883); and Schroller's *Schlesien* (3 vols. Glogau, 1885–88).

Silesia, AUSTRIAN, a duchy and crown-land of the Austrian empire, bounded on the NE. by Prussian Silesia, and on the S. and W. by Moravia and Hungary. Area, 1987 sq. m.; pop. (1880) 565,475; (1890) 602,117. Subsidiary chains of the Carpathians and Sudetic Mountains diversify the southern and western frontiers; the duchy is watered by the systems of the Vistula (in the east) and the Oder (west). The climate, though somewhat raw, is healthy, and the soil produces good crops of rye, oats, barley, potatoes, beet-root, hay, &c. Mining and manufacturing industries both flourish. The mines yield coal, iron, sulphur, and other minerals to the annual value of close upon one million sterling. The principal industries are the smelting of iron, making of machinery, the manufacture of various textiles (worsted, cloth, linen and linen thread, cottons, &c.), brewing, distilling, and the preparation of chemicals. The principal town is Troppau. This province was created a separate crown-land in 1849. There is a provincial assembly or diet of thirty-one members.

Silex (Lat., 'flint'), a generic name given by some mineralogists to all those minerals of which silica is the principal ingredient. See SILICON, QUARTZ.

Silhet. See SYLHET.

Silhouette, a profile or shadow-outline filled in of a dark colour, the shadows and extreme depths being sometimes indicated by the heightening effect of gum or some other shining material. This species of design was known among the ancients, and was by them carried to a high degree of perfection, as the monochromes on Etruscan vases amply testify: but the name silhouette is quite modern, dating from about the middle of the 18th century, though the art itself seems to have been practised in England prior to 1745. It was taken from Etienne de Silhouette (1709–67), the French minister of finance for four months in 1759, who, to replenish the treasury, exhausted by the costly wars with Britain and Prussia, and by excessive prodigalities, inaugurated numerous reforms and the strictest economy of expenditure. His earliest reforms were admirable; his later ones, however, were so capricious, short-sighted, and unsuccessful that he fell utterly from favour, and his name became a byword for injudicious parsimony; any mode or fashion that was plain and cheap was styled *à la Silhouette;* and profiles made by tracing the shadow projected by the light of a candle on a sheet of white paper, the rest of the figure being filled up in black, have continued to bear the name. Although without merit as a work of art, the silhouette presents a clear and well-marked profile, and the Pantagraph (q.v.) used to be frequently employed to obtain profiles of a reduced size direct from the human features. Profiles cut out of black paper with scissors also receive the name of silhouettes; and akin to these are the 'silhouette illustrations' to *Faust*, *A Midsummer Night's Dream*, &c., by the Prussian Paul Konewka (1840–71), or those to our own article HORSE in Vol. V. p. 794. It should be added that Littré derives the use of the word otherwise: quoting from the *Journal Officiel* of 1869 a statement that one of M. de Silhouette's chief amusements after his fall was making such shadow-portraits, and that his château of Bry-sur-Marne had the walls of several of its rooms adorned with pictures of this sort. M. de Silhouette was at an earlier date secretary and chancellor to the Duke of Orleans, and was one of the three commissioners appointed in 1749 to delimit the frontiers of the French and British possessions in Acadia. He wrote a number of works, and published three translations from the English of Bolingbroke, Pope, and Warburton respectively. See a long correspondence in *Notes and Queries* for 1882–83.

Silhouette of Robert Burns.

Silica. See SILICON.

Silicon, or SILICIUM, is one of the non-metallic elements: sym. Si; at. wt. 28·4 (O = 16); sp. gr. of crystalline form, 2·49. It may be obtained in three different forms—viz. the *amorphous*, the *graphitoid*, and the *crystalline*. It is amorphous silicon which is obtained by the processes in common use, the other forms being obtained from it.

Amorphous silicon presents the appearance of a dull brown powder, which adheres to the finger, is insoluble in water and in nitric and sulphuric acids, but readily soluble in hydrofluoric acid and in a hot solution of potash. It is a non-conductor of electricity, and when heated in air or oxygen its external surface burns brilliantly, and is converted into silica, which fuses from the extreme heat, and forms a coating over the unburned silicon. *Graphitoid* silicon is obtained by exposing the amorphous variety to an intense heat in a closed platinum crucible. This form of silicon will not take fire when heated in oxygen gas, and resists the solvent action of pure hydrofluoric acid, although it rapidly dissolves in a mixture of nitric and hydrofluoric acids; moreover, it is a conductor of electricity. Deville obtained *crystallised* silicon in regular double six-sided pyramids of a dark steel-gray colour.

Silicon, in a state of combination with oxygen, is the most abundant solid constituent of our globe; in less proportion, is an equally necessary ingredient of the vegetable kingdom; while in the animal kingdom it occurs in mere traces, except in a few special cases. It is never found in nature except in combination with oxygen; but, by a somewhat difficult process, it may be separated as a dark brown powder. It was first isolated by Berzelius in 1823. For our knowledge of the other modifications we are indebted to Wöhler and Deville.

Silicon forms two oxides, one of which is only known in the hydrated state, while the other is the well-known compound silica or silicic acid. Silica or silicic acid is represented by the formula SiO_2, and a hydrate, $3H_2O,2SiO_2$, has been obtained, while other hydrates are known to exist.

Silica exists both in the crystalline and in the amorphous form. The best examples of the crystalline form are rock-crystal, quartz, chalcedony, flint, sandstone, and quartzose sand. Silica in this form has a specific gravity of about 2·9, and is only attacked with difficulty by potash or hydrofluoric acid. The amorphous form exists naturally in opal, and is obtained artificially as gelatinous silica, &c.; it differs from the former in its specific gravity, being about 2·2, and in its being rapidly dissolved by potash and by hydrofluoric acid. Pure silica (as it occurs in rock-crystal, for example) is perfectly transparent and colourless, and is sufficiently hard to scratch glass. The heat of the oxyhydrogen blowpipe is required for its fusion, when it melts into a transparent glass, capable of being drawn out into elastic threads. Perfectly pure silica in its amorphous form may be obtained by various chemical processes. If a solution of silicate of potash or soda be treated with hydrochloric acid, the silicic acid separates as a hydrate, and on evaporating this to dryness, and treating it with boiling water, silicic acid remains as an amorphous powder, which, after being washed, dried, and exposed to a red heat, may be regarded as chemically pure. The hydrated silicic acid mentioned in the above experiment is soluble in water, and (more freely) in acids and alkalies. The solubility of hydrated silicic acid in water accounts for the presence of silicic acid in mineral springs and in the geysers of Iceland, as well as for its gradual separation from these waters in the form of petrifactions. That silica or silicic acid is a true acid (although a feeble one) is obvious from its uniting with bases, especially those which are capable of undergoing fusion, and forming true salts, known as silicates. These silicates occur abundantly in nature, all the forms of clay, felspar, mica, hornblende, augite, serpentine, &c. being compounds of this description.

Most of the silicates are fusible, the basic silicates fusing more readily than those which are either neutral or contain an excess of acid. Excepting the silicates of the alkalies, no silicates are soluble in water. The anhydrous, neutral, and acid silicates of the earths resist the action of all acids except the hydrofluoric.

Silica derives its name from the Latin *silex*, 'flint,' of which it is the essential constituent, and is largely employed in the manufacture of glass, china, and porcelain. For these purposes it is obtained in a finely comminuted state by heating flints or portions of colourless quartz to redness, and plunging them in cold water. The silica splits up into a friable mass, which may be easily ground to a fine powder. The use of silica in giving firmness and rigidity to various parts of the animal organs is exemplified in its free occurrence in the quill-part of the feathers of birds, in the shields of certain infusoria, and in the spicula occurring in sponges; while its similar use in the vegetable kingdom is seen in its more or less abundant presence in the stalks of the grasses, more particularly in the cereals and in the bamboo (where it is especially deposited about the joints, and is known as *Tabasheer*), in the Equisetæ, &c.

Silicon may be made to combine with several other elements besides oxygen, but, with the exception of silicofluoric acid, these compounds are of no practical value. Thus, silicon and hydrogen form a hydride of silicon, a colourless and spontaneously inflammable gas. Nitride of silicon is a bluish fibrous body, while sulphide of silicon is a white earthy powder. Silicon unites with chlorine, bromine, and probably iodine and fluorine, in two proportions corresponding to its oxygen compounds. Fluoride of silicon, SiF_4, is a colourless pungent gas, liquefiable under strong pressure, and solidifying at – 220°, inflammable, and a non-supporter of combustion. It is obtained by heating powdered glass with twelve times its weight of oil of vitriol, and when a stream of this gas is transmitted through water a reaction takes place; two atoms of water and three atoms of the fluoride of silicon yielding silicofluoric acid, H_2SiF_6, which remains in solution, and silicon, which is deposited. A saturated solution of this acid forms a very sour fuming liquid, which does not directly attack glass, but if allowed to evaporate on it causes erosion from the fluoride of silicon becoming evaporised, and free hydrofluoric acid being left. A dilute solution is sometimes employed in the laboratory as a precipitant of potash, which it throws down in a transparent gelatinous form. With salts of baryta it gives a white crystalline precipitate. It combines with bases to form salts.

For soluble glass, a silicate of soda or potash, see GLASS, Vol. V. p. 245; and for silicate cotton, see SLAGS.

Silique (*Siliqua*), in Botany, the fruit of the Cruciferæ. See FRUIT, Vol. V. p. 19.

Silistria, a town of Bulgaria, is situated on the right bank of the Danube, here 1½ mile wide, about 70 miles NW. of Varna. Owing to its strategic position it has for many centuries been a more or less formidable fortress, especially since the 14th century, under the dominion of the Turks. The Roman *Durostorum*, it was captured by the Russians under Sviatoslaff in 867, but was recovered in 971 by the Byzantine emperor, John Zimisces. It has been repeatedly besieged by the Russians. They destroyed the works after capturing it in 1810; but the fortifications were rebuilt more strongly than before, and offered a stout resistance to the Russian attacks in 1828–29. In 1849 it was made a stronghold of the first class, and was rendered almost impregnable by the addition (1853) of twelve detached forts on the south and east. On the outbreak of the Crimean war the Russians laid siege to it with an army of from 60,000 to 80,000 men, but were compelled to retreat after thirty-nine days. In 1877, again, it successfully defied the troops of the czar. The Congress of Berlin in 1878 decreed that the fortifications should be dismantled; but this has not been given effect to. Pop. (1888) 11,414, who weave cloth, tan leather, and grow vegetables.

Silius Italicus, a minor Latin poet, was born in 25 and died in 101 A.D. At an early age he became a prominent forensic orator, was consul the year of Nero's death (69), became a familiar friend of Vitellius, and was afterwards proconsul in Asia. He was a devoted student of Cicero and Virgil, and owned their estates at Tusculum and Naples. In old age, finding himself labouring under an incurable disease, he starved himself to death. His epic poem, *Punica*, in seventeen books and about 14,000 lines, has come down entire, and remains a monument of industry, of patient imitation, not of poetic creation. Scipio and Hannibal are its Achilles and Hector, its Æneas and Turnus; and every episode in his great originals is slavishly reproduced and degraded to a dead level of literary mediocrity.

The poem was discovered by Poggio about 1416, and the *editio princeps* appeared in 1471. Editions are by Ernesti (1791) and Lemaire (1823).

Silk. The Chinese appear to be the first people who applied themselves to sericulture, although some claim for the Tussur silk of India the earliest silk fibre used. The words *Seres* used by Theophanes and *Serinda* by Procopius were in all probability so used to indicate that part of the East, which was no doubt China, where the silk industry existed at a very remote period. Ptolemy was the first to use the word *Series* for China, or

Company.

rather the northern part of it, known later as *Cathay;* and the name is derived from the Chinese name of the silkworm *sze*, *see*, or *si*, in Corean *sir*, whence the Greek *σήρ*, 'the silkworm;' *σῆρες*, 'the people furnishing silk;' and *σηρικόν*, 'silk.' The Latin *sericum* has been traced direct to the Mongol *sirkeh;* and the *serikoth* of Isaiah, xix. 9, has been supposed to be silk. From *sericum* is derived the French *soie;* and etymologically connected with it are the German *seide*, the Russian *sheolk*, the Anglo-Saxon *seolc*, the Icelandic *silke*, and the English *silk*. We are informed by Hawae-nan-tze, in a Chinese work called the *Silkworm Classic*, that Se-ling-she, the principal queen of Hwang-te (2640 B.C.), was the first to rear silkworms, and the Emperor Hwang-te was induced to invent robes and garments from this circumstance. The Chinese historians carry back the cultivation of the mulberry and the breeding of silkworms to the mythic period. If they are to be believed, the art of silk-reeling was known in China in the time of Fouh-hi, a century before the date usually assigned to the biblical deluge, and Hwang-te's queen did not disdain to share in the labours attending the care of the insect, as well as in those of the loom, the invention of which seems to be attributed to her, and to have raised her to the position of a tutelary genius with special altars of her own. But whatever the precise date of the discovery, it appears there can be no question of the very high antiquity of the knowledge of the worm and its product in China. A series of imperial edicts and voluminous literature of practical treatises testify to the importance of the industry and the care that was taken to foster an art which was considered, according to M. de Rosny, 'best fitted to promote the morality of the people and extinguish pauperism in the empire.' The queen and wives of the nobles through successive generations personally attended to the rearing of the silkworms. That this silk was of the mulberry-fed kind is evident from a further extract from the *Silkworm Classic*, which says that afterwards 'When Yu regulated the waters (2200 B.C.) mention is made, in his work on the tribute, of the land adapted for the mulberry-tree having been supplied with silkworms, from which time the advantage thereof gradually increased.' It is not known whether silk was utilised in India at so early a period as this—probably not; but that India learned the art from China is generally believed, although at what period is not known.

About the middle of the 6th century A.D. the western world received a supply of silkworms' eggs. They were conveyed from China to Constantinople by two Persian monks who had gone to the East as missionaries, and had observed in China the various processes connected with the rearing of silkworms, the nature of the trees on which they fed, and the preparation of the silk. This occurred in the year 552, in the reign of Justinian, who gave every encouragement to the introduction of the valuable insect. The eggs were secretly conveyed from China within a hollow cane; at the proper season they were hatched, and the caterpillars were fed on the leaves of the wild mulberry-tree. The monks continued to superintend at Constantinople the rearing of the insects and the whole process of manufacturing the silk. From this small commencement the myriads of silkworms have sprung which throughout eastern and western Asia have met the demand for silk—a demand that has gone on increasing from that time to the present.

Natural and Life History.—The natural history of every kind of silk may be briefly stated. From a small egg laid by the moth, of whatever species, appears in due season a small larva, or caterpillar, or worm, as it is usually called. This worm, after having lived its day, feeding only on the leaves of certain plants specially suited to its own species, and increasing in size, spins, or rather secretes, a fine silk thread around itself for a covering and protection during the time it lies dormant in the next stage of its existence. As soon as it has secreted all the silk, it changes into a pupa or chrysalis, and remains inside its silken cell until the time for its appearance as an imago or perfect moth, having four scaly wings, with six legs, and two antennæ, which are larger in the male than in the female. When its hybernation is ended it emits a fluid which softens the end of its cocoon cell, and, by means of its wing-spines and legs, parts the fibres aside until the opening is large enough for it to creep out. After a short time its wings expand and dry, and it enters into a perfect state. It lives only a few days in this phase of existence. It is in this stage only that the race is perpetuated, the female laying a number of eggs and dying soon afterwards (see the articles INSECTS, CATERPILLAR, CHRYSALIS, COCOON).

There are a number of species of silkworms whose food is the leaves of the mulberry-tree, the principal and most useful of which is the *Bombyx mori*. The following is a list of mulberry-feeders, the various kinds of Bombyx alone being domesticated, the others being wild:

Bombyx mori (Linnæus).—The common silkworm, domesticated in China, Bokhara, Afghanistan, Cashmere, Persia, South Russia, Turkey, Egypt and Algeria, Italy, France, and Spain, in all which countries it produces but one crop annually, spinning the largest cocoon and the best silk of a golden yellow or white.

B. textor (Hutton).—The Boro Poloo of Bengal, domesticated in South China and Bengal; an annual only, producing a white (sometimes yellow) cocoon of a different texture and more flossy than *B. mori*.

B. sinensis (Hutton).—The Sina, Cheena, or small Chinese monthly worm of Bengal, introduced from China, and partially domesticated in Bengal; produces several broods in the year; cocoon white and yellow.

B. crœsi (Hutton).—The Nistri or Madrassee of Bengal, introduced from China, and domesticated in Bengal; yielding seven or eight broods of golden yellow cocoons in the year of larger size than *B. sinensis*.

B. fortunatus (Hutton).—The Desi or Chota Poloo of Bengal; yields several broods annually, spinning the smallest cocoon of a golden yellow colour.

B. aracanensis (Hutton).—The Burmese silkworm, domesticated in Arakan, said to have been introduced from China; yields several broods annually; cocoons larger than the Bengal monthly species.

Theophila huttoni (Westwood).—The wild silkworm of the north-west Himalayas, feeding on the indigenous mulberry in the mountain forests.

T. sherwilli (Moore).—The wild silkworm of the south-east Himalayas.

T. bengalensis (Hutton).—The wild silkworm of Lower Bengal, discovered in the neighbourhood of Calcutta, feeding on *Artocarpus lacoocha*. Found also at Ranchee, in Chota Nagpore.

T. religiosa (Helfer).—The Joree of Assam and Deomooga of Cachar. Feeds also on the ber tree (*Ficus bengalensis*) and the peepul (*F. religiosa*).

T. mandarina (Moore).—The wild silkworm of Chekiang, North China; said to feed on wild mulberry-trees, spinning a white cocoon.

Ocinara lactea (Hutton).—Mussooree, north-west Himalayas; also feeds on *Ficus venosa*, spinning a small yellow cocoon, yielding several broods during the summer.

O. moorei (Hutton).—Mussooree; also feeds on *F. venosa*, as well as on the wild fig, spinning a small white cocoon. It is a multivoltine (see below).

O. diaphana (Moore).—Khasi Hills.

Trilocha varians (Walker).—North and South India.

In Italy and France *B. mori* is cultivated under active government encouragement and oversight, having during centuries of effort become a subject of high national importance. The United

States of America and the British colonies are making efforts to introduce the cultivation of the *B. mori;* the only hindrance being in the high price of labour for cocoon reeling. The *B. mori* is univoltine or annual; but the *B. fortunatus* and *B. crœsi,* which are confined to Bengal, are multivoltine —i.e. they produce several broods annually. For wild silks not from mulberry feeders, see page 456.

Classification.—The silk-producing Lepidopterous insects are of many species, possessing very marked structural differences, whilst the variety and quiet beauty of their colours, and in many species their large size, contribute greatly to the charm of studying this branch of natural history. They belong to the order Lepidoptera, sub-order Heterocera or Moths, group Bombycina, and to several of the twenty-seven or more families which compose this group, the most important being the Bombycidæ and the Saturnidæ. All the Saturnidæ are silk-producers, but not all the Bombycidæ. Recent researches have resulted in adding many new or previously unknown species to the list of silk-producers, and the known number is now upwards of 400, and the list is by no means complete.

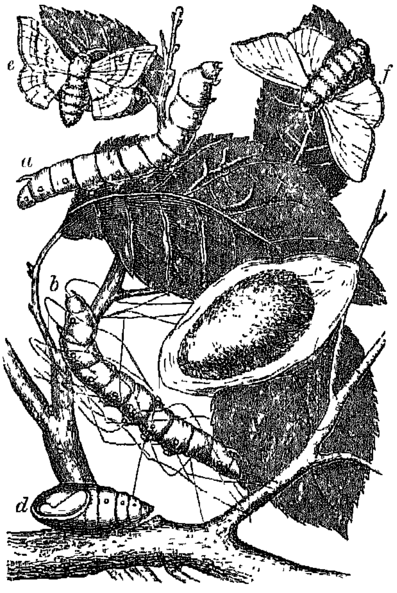

Fig. 1.—Common Silkworm (*Bombyx mori*): *a*, larva, full grown; *b*, larva, seripositing; *c*, cocoon; *d*, chrysalis; *e*, female moth; *f*, male moth.

The Bombycidæ have a very short and rudimentary proboscis, live for a very brief time in their perfect state, and take little or no food; the body is thick and hairy; the antennæ are pectinated. The caterpillars feed on the leaves and other tender parts of trees or other plants; the chrysalises are enclosed in a cocoon of silk, which gives to some of the species a great economical importance. The most important is the Common Silkworm (*Bombyx mori*), cultivated chiefly in China, Japan, Italy, and France. The perfect moth is about an inch in length, the female rather larger than the male; the wings meeting like the sides of a roof; the colour pale buff with a broad pale brown bar across the upper wings. The females generally die very soon after they have laid their eggs, and the males do not survive much longer. The eggs are numerous, about the size of a pin's head, not attached together, but fastened to the surface on which they are laid by a gummy substance, which, when dry, becomes silky. In Europe they are laid in spring, and are hatched in summer. The caterpillar is at first very small, not more than a quarter of an inch in length, but rapidly increases in size, till, when full grown, it is nearly 3 inches long. It is of a yellowish-gray colour. The head is large. On the upper part of the last joint of the body is a horn-like process. The skin is changed four times during the growth of the caterpillar. Before each change of the skin it becomes lethargic and ceases to eat, whereas at other times it is very voracious. When the skin is ready to be cast off it bursts at the forepart, and the caterpillar then, by continually writhing its body, without moving from the spot, thrusts it backwards; but silkworms frequently die during the change of skin. A very rapid increase of size takes place whilst the new skin is still soft. The natural food of the silkworm is the leaves of the white mulberry, but it will also feed on the leaves of some other plants, as the black mulberry and the lettuce. When so fed, however, it produces silk of inferior quality. The silk-producing organs are two large glands (*sericteria*) containing a viscid substance; they extend along great part of the body, and terminate in two seripositors in the mouth. These glands become very large when the change to the chrysalis or pupa state is about to take place. When about to spin its cocoon the silkworm ceases to eat, and first produces the loose rough fibre which forms the outer part of the cocoon, and then the more closely disposed and valuable fibre of its interior. In this process the position of the hinder part of the body is little changed, but the head is moved from one point to another; and the cocoon when finished is much shorter than the body, which, however, being bent, is completely enclosed in it. The cocoon is about the size of a pigeon's egg. Each fibre of silk or *bave*, when examined by a microscope, is seen to be double or of two *brins*, being equally derived from the two silk-producing organs of the caterpillar. The bave or double thread often exceeds 1100 feet in length. The time of the silkworm's life in the caterpillar state is generally about eight weeks. About five days are occupied in the spinning of the cocoon, after which about two or three weeks elapse before the cocoon bursts and the perfect insect comes forth. The opening of the end of the cocoon by the moth for its escape is, however, injurious to the free and perfect reeling of the silk from the cocoon, and the silkworm rearer prevents this by throwing all the cocoons into hot water or more usually into an oven, called in France *étouffoir*, *séchoir*, heated by hot air or by steam, except those which he intends to keep for breeding. These he selects with care, so that he may have about an equal number of male and female insects, the females being known even in the chrysalis state by their larger size. The cocoons intended for the production of moths are placed on a cloth in a somewhat darkened room, of which the temperature is near, but does not exceed, 72° F.; and the moths, when produced, show no inclination to fly away, but remain on the cloth, lay their eggs, and die there. It is an interesting peculiarity of this valuable species of moth that neither in the caterpillar nor in the winged state does it show that restless disposition which belongs to many others, the caterpillars remaining contentedly in the trays or boxes in which they are placed, feeding on the leaves with which they are there supplied, and at last only seeking a proper place for making their cocoons for their covering and protection. Whilst assuming the chrysalis state small bundles of twigs are placed above the feeding-trays for the worms at their last caterpillar stage to resort to for cocoon building. Owing to this peculiarity or domesticity, it is capable of being reared and managed in a way which would otherwise be impossible.

Rearing of Silkworms.—It is of the first consequence in the production of silk that one of the species of mulberry should be cultivated, and that it should be so favourably situated as to climate that it is in readiness for feeding the worms. The species best adapted is the white mulberry, *Morus alba*. The extreme lateness of season at which the black mulberry produces its leaves prevents its employment generally, besides which it will not bear the loss of its leaves so well. It is said that in some parts of China the silkworm is easily reared upon the trees in the open air. So little has it a tendency to wander far from the place of its birth, if food be at hand, that it only requires a warm, dry atmosphere to bring it to perfection; but usually, even in China, and in all other countries, it is thought desirable to raise the silkworm in properly arranged buildings, and to supply it with mulberry leaves gathered from day to day. In India, China, and other tropical countries the eggs hatch readily at the proper time by the natural heat; but in southern Europe artificial heat is almost always required; formerly the heat of fermenting dung was found serviceable, and the warmth of the human body was also used, the eggs being carried in little bags in the bosom of the cultivator; but now they are regularly hatched by stove-heat, beginning with a temperature of 64° F., which is gradually increased through ten days to 82°, at which it is maintained until the eggs are hatched. Experience has shown that the operation is facilitated by washing the eggs in the first place with clean water; and some cultivators also wash them in wine, the value of which is very questionable. Washing is found to remove a certain gumminess and other impurities from the eggs which would otherwise impede the hatching. When the silkworms have been regularly developed as above described, it is usual to place above the trays contrivances for the caterpillar to spin within. In feeding the worms care is taken so to distribute the food on the shelves or in the trays that the insects shall not crowd together; and for this reason the most careful cultivators chop the leaves small, and strew them very evenly about. Great care is taken not to let the worms of one hatch mix with those of another, unless of exactly the same age, otherwise the stronger insects would deprive the younger of their food. Many other niceties of attention are required, which altogether render the successful rearing of silkworms a matter of much anxiety and labour.

Diseases.—Silkworms are subject to various diseases. In all about fifteen have been defined, but the most important, which only need mention here, are *Muscardine*, *Pebrine*, *Flacherie*, *Guttine*, and *Grasserie*. *Muscardine* is the result of the growth on the silkworm of a microscopic fungus named *Botrytis bassiana*. The spores of this minute fungus are not larger than the two millièmes of a millimetre. They are carried by the air, and falling on the mulberry leaves or on the worms cause the disease. Worms affected with muscardine die before arriving at the moth. In the magnaneries where the disease is present or is suspected they are daily fumigated with sulphurous acid gas (fumes of sulphur), which kills the spores, but does not hurt the worm. *Pebrine* is the most important disease. Worms affected with it are without difficulty detected; amongst other well-known signs by the appearance of blackish spots on the skin. This disease is the consequence of a corpuscle or bacillus, which, once having entered the worm, multiplies rapidly. The interior of the body of a moth is often found to be quite full of corpuscles. Pebrine is found in all the life stages of the insect. Prevention is the remedy laid down by M. Pasteur, and in all well-managed rearing-houses the microscope is employed to examine the eggs, when those found to be pebrinised are rejected. This method, combined with greater cleanliness, desiccation, and fumigations of chlorine, has been so successfully used since 1865 that pebrine has nearly disappeared in a number of localities in France and Italy where previously sericulture had become almost extinct, and it now only exists where these precautions are not sufficiently observed. *Flacherie* is a deadly and contagious disease, and is the result of bacterial growth of a vibrionic nature. The worms are attacked in their last stage, having arrived at their full size; they languish, die, and decompose rapidly, a whole chamber sometimes perishing in a day. Pasteur has fully studied this disease, and has pointed out preventive remedies. It is generally the result of other diseases and the want of proper precaution, especially as to the careful conservation of the eggs from the laying of them to the time they are hatched. *Guttine* is a disease of the same character, and is probably only a modification of flacherie. *Grasserie* is of less importance than the other diseases; but it is interesting and not very well understood. A few worms will frequently be found in the midst of healthy ones, which are evidently ailing, crawling slowly, with a glossy skin, becoming thinner and longer. In the yellow races the colour becomes bright, and in the white races an unhealthy milky-white appearance, and through the skin there exudes a dirty liquid which under the microscope is seen to contain a multitude of many-sided globules, probably albuminous. A cold, stagnant, or damp atmosphere, or a too crowded chamber, favours the commencement of this disease, which is neither hereditary nor contagious.

Preparation of Silk.—When the cocoons are completed, which is known by the absence of any sound within, they are carefully sorted, and a certain number are kept for breeding. The sexes are readily known by the difference of shape as well as of size. The French growers sort them into several varieties; those which are less compact, or in which the worm has died—a fact known by external indications—being separated from the good ones. When the sorting is finished, the cocoons are placed in an oven with a gentle heat, which kills the enclosed chrysalis—otherwise they would all become perforated by the insect eating through; they are then prepared for winding by first removing the flossy covering, which is often somewhat hard and compact. The cocoons are placed in basins of water, kept warm by charcoal fires, or in the larger establishments by steam. This softens the natural gum which coats the silk, and loosens the various coils of silk adhering together in the cocoon. The operator then takes a small battage brush made of twigs and stirs them about in the water. This catches the outside portions of the cocoon, from which the reelable thread is gradually unwound. From three to five of these ends are taken and united into one thread, which is passed through a polished metal or glass eye in the reeling-machine. In large filatures or silk establishments complex machinery is used for winding; but reeling apparatus of greater simplicity is used by the Chinese, East Indians, and others. In all cases, however, the principle is the same. The plan most generally adopted in Italy is shown by fig. 2.

Great care and skill are required in reeling silk from the cocoons, because, although the reeler starts with four or five or six cocoons, not only are their individual threads apt to break, but they are not all of the same length, so that one will run out before the others. These matters are carefully watched, and, as often as a thread breaks or a cocoon runs out, another thread is joined on and is made to adhere to the compound thread on the reel by its natural gumminess. Each cocoon generally yields about 300 yards of thread, so that it takes 1200, 1500, or 1800 yards to make 300 yards of the filament of raw silk, by which name the reeled silk is always known. The raw silk is made up into hanks of various sizes. That from China and Japan is tied in packages of six hanks each, technically called books, and sometimes the ends of these books are covered with silken caps very curiously formed out of unreeled cocoons macerated and felted into a thin material, so managed as to form a filmy cap sufficiently large to cover a man's head. Formerly all raw silk required to be made into compound and twisted threads was termed thrown silk, but at the present time much is woven in the raw state and afterwards dyed in the piece. The raw silk is used for the warp, and spun silk and cotton for the weft, of the cheaper kinds of silks, such as foulards and some satins, made in large quantities in Lyons.

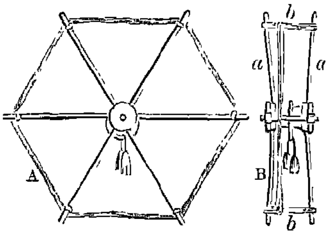

Fig. 2.

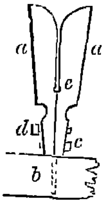

Fig. 3.

When the silk has to be thrown into organzine or tram, the raw silk is put into warm soap and water to soften the gum, so as to make the hanks wind more easily. The hanks are placed on large skeleton reels called swifts (A, B, fig. 2), so adjusted that they will hold the hanks tightly. B, the edge view, shows that the spokes, *a*, *a*, are in pairs. They are made of thin pieces of lancewood, and each pair are rather nearer together at the axle than at the circumference, where they are connected together by a small band of cord, *b*, *b*. These bands are so tied that they will slip down easily to admit of the hanks being placed; then, by pushing the cords upwards, the hank can be stretched to its fullest extent. This is necessary to compensate for the varying lengths of the hanks received from the different countries. When the swifts are set in motion the silk is carried from the hanks to bobbins, upon which it is wound for the convenience of further operations. The bobbins are then taken from the winding to the cleaning machine, when they are placed on fixed spindles, so that they will turn with the slightest pull; and the thread is passed through a small apparatus attached to the machine, which is specially called the cleaner, and consists essentially of two polished smooth-edged blades of metal (*a*, *a*, fig. 3) attached to a part of the frame of the machine, *b*. They are held together by the screw, *c*, and are slightly opened or closed by the other screw, *d*, so that the thread can be put between them down to the small orifice, *e*, and then, by tightening the screw, preventing its return after passing through this small hole, which is the gauge of the thread, and which removes any irregularities or adherent dirt. The silk next passes over a glass or metal rod, and then through another small hole, much larger than that of the cleaner, and usually made of glass, on to the bobbin, upon which it is wound by the action of the machine. The next process is twisting the cleaned thread, by which it becomes better adapted for being combined with other threads. Doubling is the next process, and this consists in running off a number of bobbins of twisted silk on to one bobbin of a larger size, which is put into the throwing machine, when the ends of the doubled silk are passed through a smooth hole on to a large reel, which reel winds it into hanks, but twisting the threads into a fine cord as it goes from the bobbins to the reel. After this the hanks have to be again wound on reels and bobbins for the weaver, the former for the warp and the latter for the weft. If it has been wound, cleaned, and thrown it is called thrown-singles; if wound, cleaned, doubled, and thrown, it is called tram, and is used for the richer silks and velvets, but only for the weft or shute; and if wound, cleaned, spun, doubled, and thrown, it is called organzine, and is used for the warps of fabrics. Before winding the cocoons a flossy portion has to be removed; and after all has been wound off another portion remains like a compact bag; these are collected and sold under the name of waste-silk, and to these are added the fragments of broken threads, which accumulate in considerable quantities during the reeling and throwing operations. Formerly very little use was made of waste-silk; not a little of it was employed by engineers and others for mere cleaning purposes; although as early as 1671 a proposition was made by a manufacturer named Edmond Blood to make it available by carding it with teasels or roving-cards. He took out a patent for this invention, but apparently did not bring it into use.

It has been left to the 19th century to perfect the spinning into yarn of waste-silk. Mr Lister of Bradford (in 1891 created Lord Masham) in 1857 discovered a successful method of spinning native Chassum, or Indian silk-waste, there being then a very considerable quantity warehoused in London, for which, however, no use had been found. Since that period many important improvements in dressing and spinning waste-silk have been invented, and a great trade has resulted in the manufacture of fabrics made from these yarns in Yorkshire, Alsace, Switzerland, and France. Another patent was taken out by Mr Lister, which has done wonders; now the waste is all spun into yarn, thereby greatly economising the use of silk, as the quantity of silk-waste always greatly exceeds the amount of good silk reeled off. The processes employed in the production of silk-yarn from the waste differ little from those of spinning, especially for cheap and common qualities of cotton and wool.

The following silk centres represent the present and past localities of British silk manufacture: London (Spitalfields), Derby, Coventry, Sherborne (Dorsetshire), Sudbury, Glemsford and Haverhill (Suffolk), Braintree, Yarmouth, Bungay, Leicester, Nottingham, Norwich, Macclesfield, Leek, Congleton, city and district of Manchester, Rochdale, Bradford, Halifax, city and district of Glasgow, city and district of Dublin, Tideswell (Derbyshire). Leek is justly celebrated for its manufactures of sewing and embroidery silks, a branch greatly increased since the introduction of the sewing-machine, which necessitated long and evenly-made lengths of silk thread of many sizes and colours. Leek has become the largest centre of dyeing silk in England; it is noted for the production of a special 'raven black,' nowhere else produced, and so called from its resemblance to the bluish-black plumage of a raven's wing. It is said that this shade is partly owing to the peculiar quality of the water used in dyeing. Silk is also dyed in London, Glasgow, Macclesfield, Coventry, Middleton, and other places, but to a much diminished extent.

Statistics.—About 100 lb. of cocoons are raised from 1 oz. of eggs, and 12 to 14 lb. of cocoons yield 1 lb. of raw silk; but the quantity is variable, and depends on silkworm study, selection of eggs, and in crossing the numerous varieties. As far as can be ascertained, the total quantity of raw silk annually produced in the world is upwards of 22 millions of pounds. China furnishes 38·53 per cent.; Italy, 29·65 per cent.; Japan, 12 per cent.; France, 7·52 per cent.; the Levant, 6·21 per cent.; India, 3·82 per cent.

Of silk manufacturing countries France is the principal. The French consumption of raw silk amounts to about 9,918,000 lb. per annum, the value of which is estimated at from £10,000,000 to £12,000,000. France itself produces about one-eighth of the raw silk consumed (there were 242,000 growers in 1890); the rest being imported from Italy and Asiatic countries. The total value of manufactured silk produced by France is estimated at from £24,000,000 to £26,000,000 per annum; the total production of the world being £64,000,000. France thus produces about two-fifths of the whole, the total number of silk looms in France being estimated at 230,000.

The British silk trade was formerly much larger than it is at present. The treaty with France which allowed French silks to come in duty free found Great Britain and Ireland unable to compete with France, and in a short time the trade dwindled immensely, with disastrous results to Spitalfields, Coventry, Macclesfield, Congleton, Dublin, Manchester, and a few other centres. From this it has never recovered; but it is hoped by the promotion of a higher efficiency, and by the equalisation of wages and hours of labour throughout the Continent, that Britain may once more come to enjoy her fair share in this important and beautiful industry, having a climate splendidly suited for all stages of manufacture, though not for sericulture. The following figures, taken from the Board of Trade returns of 1890, show the total quantity of silk manufactured in Great Britain.

Raw	262,168 lb.	= £173,138
Knubs or husks of silk and waste	11,189 cwt.	= £114,893
Thrown	124,140 lb.	= £90,110
Manufactures		£935,730

The history of silk production in America dates from 1530, when the first mulberry-trees and silkworms were imported into Mexico. But by 1600 the industry had died out there; and a like fate overtook it in Virginia before the end of the next century, and practically everywhere by the beginning of the 19th century, although it had been vigorously encouraged by England, filatures established, and Georgia alone in one year had sent home nearly 2000 lb. of raw silk. About 1825 a powerful effort was made to revive the industry in the United States; silk societies were established, and manuals of silk-culture, such as J. H. Cobb's, printed and distributed by state legislatures and by congress. But success was prevented by a craze for speculation in Chinese mulberry-trees, which ended in wide-spread ruin in 1839. Since then silk-culture has never flourished in America. It was taken up with eagerness in California in 1854, but quickly dwindled and died; there is a state board of silk-culture in San Francisco, but it has not succeeded in arousing much interest in it. At Philadelphia a Woman's Silk-culture Association was founded in 1876, so far with the same result; nor has commercial success encouraged the attempts of the Agricultural Department, which established a filature at Washington in 1886 for reeling silk from American cocoons, and has distributed eggs of large Milanese silkworms. But if silk-culture has failed so far to engage American attention and capital, the reverse has been the case with the silk manufacture. This began in New England early in the 18th century, and steam-power for the manufacture of sewing-silk was introduced in 1810, improved machinery quickly following, until before the civil war a great trade had grown up in twist, dress-trimmings, ribbons, and woven silk goods. Laces were manufactured at Brooklyn in 1871, and since 1876 silk handkerchiefs, tapestry, and velvets, besides dress-silks of all sorts, have been manufactured in steadily increasing quantities and excellent qualities. The most famous seat of the American silk manufacture is Paterson (q.v.), with considerably more than 100 mills. In 1874 the value of all silk goods manufactured in the United States was $16,269,157; in 1880 it was $34,519,723. In 1880 2,562,236 lb. of raw silk was imported; in 1890 this had risen to 7,510,440, valued at $24,325,531, whilst manufactures of silk to the amount of $38,686,374 were imported.

Wild Silks.—This is a generic term generally signifying those silks used in commerce, and those not at present utilised, other than silk of the mulberry-feeding worms, but relates almost entirely to the Saturnidæ, whose fibres are more or less flat; it necessarily includes a few species which are subject to more or less of domestication, such as the Eria and Muga of Assam. Most of the principal wild silkworms are Asiatic. The best known are those of India. There are a few species in North America, one or two of which have received some attention. South America and the West Indies contain many others, and are almost unworked fields. The following list includes all the principal wild silks:

Atlas and Eria Group.—Attacus atlas, A. silhetica, A. edwardsia, A. cynthia, A. ricini, A. canningi, A. lunula, A. obscurus, A. guerini.

Actias Group.—Actias selene, A. sinensis, A. leto, A. mœnas, A. ignescens.

Tussur and Muga Group.—Antheræa mylitta, A. andamana, A. mezankooria, A. frithii, A. nebulosa, A. helferi, A. perrotteti, A. assama, A. roylei.

Miscellaneous Group.—Salassa lola, Rinaca zuleika, Rhodia newara, Caligula thibeta, C. simla, C. cachara, Neoris huttoni, N. shadulla, N. stoliczkana, Saturnia cidosa, S. grotei, S. lindia, S. anna, Lœpa katinka, L. sikkima, L. sivalica, L. miranda, Cricula trifenestrata, C. drepanoides, Antheræa pernyi, A. confuci, A. yama-mai, Saturnia pyretorum, Neoris shadulla, Theophila mandarina.

Of these a few species only need be noticed here. *Antheræa yama-mai* is a Japanese species, which feeds on the leaves of the oak. It is peculiar to Japan, and has long been held in high estimation there, more so formerly than now. At one period its silk was solely reserved for the use of royalty, and the penalty of death is said to have been inflicted upon any person found using it or taking the eggs. At the present time it is woven along with the ordinary silk of commerce in patterns, giving the separate effects of each silk. The Eria silk is the product of the Eri or Arindi worm of Assam. It is largely cultivated in that part of India, and is handspun and woven by the natives in garments, rough, but so durable that mothers are said to leave them to their daughters. The cocoon is soft and not compact; it has hitherto been found impossible to unwind it in a continuous thread, and in consequence of this difficulty it is rudely spun by hand like flax. It would be largely employed in Europe for machine-spinning if it could be cultivated and exported in quantity. Its excellences for this process of manufacture are well known. The worm chiefly feeds on the *Ricinus communis*, or castor-oil plant. *Attacus cynthia* is a species closely allied to *Attacus ricini*. It comes originally from China, and feeds on the Ailanto (q.v.) tree. Its cocoons were first received in Europe in November 1856, and hatched out the following year, and towards the middle of May 1857 the first living specimen of *Attacus cynthia* was born in Europe. These cocoons were sent by Abbé Fantoni, a Piedmontese missionary, from the province of Shan Tung, in the north of China, situate just south of Pekin, to some friends at Turin. This species was first introduced into England in 1859, and reared by Mr F. Moore of the East India Museum. The larvæ, feeding on the castor-oil plant, and hatched from eggs sent by M. Guerin Meneville, were exhibited by Mr Moore before the Entomological Society of London in October 1859. Afterwards Lady Dorothy Nevill cultivated that species extensively, and planted in her park in the south of England a number of Ailanto trees. Dr Wallace also wrote on this silkworm, and considerable efforts have been made in France and in England to domesticate it, but without success. The *Attacus atlas* is found over India. It is the largest known moth, being often 10 inches in expanse of wing. The cocoon is large, but the fibre is coarse; it has not hitherto been used in the reeled state, but it is utilised in the Nepal Terai by the Mechi people, in the form of rudely-made cloths. The warp and weft are handspun yarns of long staple. The *Antheræa assama* or Muga silk is confined to Assam, and is largely cultivated for native purposes. A little is exported to Dacca and Calcutta for embroidery purposes. Could the natives be induced to cultivate it on a commercial scale for exportation it would have a widely extended use, for it is a silk that could easily be utilised for many European purposes.

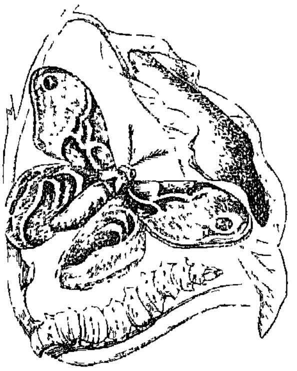

Fig. 4.—Ailanthus Silkworm (*Attacus cynthia*), reduced, showing Cocoon attached to a leaf.

The last two silks are the principal wild ones; they may from their similarity be classed as one, and are known under the name of Tussur silk—a name said to be derived from *tasara*, a weaver's shuttle. The species known as *Antheræa pernyi* is a native of China; the worm feeds on the leaves of the oak. It is very largely cultivated for export to Europe. That known as *Antheræa mylitta* is the principal species, and is exclusively Indian, being found over all parts of the country, particularly in Bengal. The Tussur silkworm when fully grown is very large and beautiful. It is about 5½ inches long. Its cocoon is hard and compact; the silk is of a deep fawn colour, which has to be resolved before any delicate shades of colour can be dyed upon it. The rapidly extended utilisation of this silk is very wonderful. About 1871 its European use was almost confined to the wearing of native-made cloths in the undyed state, and the consumption was extremely small; but in consequence of improvement in the bleaching and dyeing of this silk, at first effected by the writer of this article, as well as to his suggested utilisation, its importation has now become a factor of serious import. The fibre is well adapted for pile fabrics, and very large quantities are used in Yorkshire for the manufacture of seal cloths, a fabric resembling sealskin. France has taken up the utilisation of this silk for trimming and upholstery purposes, and the present consumption at Lyons averages 100 bales per week, and as such bales contain 130 to 140 lb. the weekly consumption there amounts to so large a quantity as about 140,000 lb. The fibre of Tussur silk is flat or tape-like, and much thicker than the ordinary silk of commerce.

The following table gives the results of the measurements of the principal silk fibres, also their strength and tension.

Name of Worm or Silk.	Country.	Diameter in fractions of an inch.		Tension or limit of stretch before breaking, in inches, of single fibre one foot long.		Strength of single fibre in drachms avoirdupois.		Dimensions of Cocoon in inches.
		Outside of Cocoon.	Inner part of Cocoon.	Outside of Cocoon.	Inner part of Cocoon.	Outside of Cocoon	Inner part of Cocoon.

Silk-cotton. Under this name various silky fibres are from time to time brought from tropical countries to Europe; they are all of the same general character, and are chiefly produced by the trees composing the genus Bombax and other genera included in the natural order Malvaceæ. These trees are natives of the tropical parts of Asia, Africa, Australia, and America. The fibre fills their large woody capsules, enveloping the seeds contained in them, and is produced in great abundance; but is too short, too smooth, and too soft to be spun into yarn by machinery. Silk-cotton is, however, used for stuffing pillows, mattresses, sofas, &c. to a limited extent in England, but more largely in Holland, where a long-stapled variety is obtained from Java. One of the best-known silk-cotton trees is *Bombax malabaricum*, a very large soft-wooded tree growing in India, Burma, Java, and North Australia. Its fibre is called *simal.* Another of these trees is *Eriodendron anfractuosum,* which is found in tropical countries of both hemispheres, and which yields the fibre known in India as *rapok. Cochlospermum gossypium,* a small Indian tree, also yields a silk-cotton. A beautiful fibre of this kind is obtained in the West Indies from *Ochroma lagopus. Vegetable silk,* which, like silk-cotton, is only suitable for stuffing, is the covering of the seeds of *Chorisia speciosa,* a Brazilian tree.

Silkworm Gut, a material used by anglers for dressing the hook-end of the fishing-line. It consists of the drawn-out glands of the silkworm at the time it is about to spin its cocoon and when these glands are fully distended. The worms are immersed for twelve or fourteen hours in strong vinegar, and then taken separately, and pulled asunder. The skilled operator knows by the strength of the silk-gut if the soaking in vinegar has been sufficient, and if so he lays hold of the ends of the two silk-glands and draws them out gently to the proper length—and so the gut is formed. He then stretches a number of these lengths separately across a board, fixing them at each side or end by slits or pins, after which they are exposed to the sun to dry. Silkworm gut is a very strong material. It is prepared in Italy and Spain.

Sillery, a village of 400 inhabitants in the French department of Marne, near Rheims, famous for its Champagne (q.v.).

Silliman, Benjamin, American physicist, was born at North Stratford (now Trumbull), Connecticut, August 8, 1779. His father was a colonial judge, and a brigadier-general in the war of independence. He graduated at Yale in 1796, was appointed a tutor in 1799, and was admitted to the bar in 1802, but soon after received from the college the appointment of professor of Chemistry, and proceeded first to study this subject, attending lectures on chemistry for three years at Philadelphia, and in 1805-6 at Edinburgh (on geology also) and London. His chair he filled till 1853, and for two years longer lectured on geology. In the course of many experiments in 1822 he first established the fact of the transfer of particles of carbon from the positive to the negative pole of the voltaic battery. From 1808 he delivered popular lectures on chemistry and geology in many parts of the country, and interested in these subjects many who afterwards became among the foremost of American scientists. In 1840 Professor Silliman was elected the first president of the American Association of Geologists and Naturalists—since grown into the American Association for the Advancement of Science. In 1818 he founded the *American Journal of Science,* better known as *Silliman's Journal,* of which he was for twenty years the sole and for eight more the principal editor. In 1830 he published a text-book on chemistry; he edited several editions of Bakewell's *Geology* and of Henry's *Chemistry;* and in 1853 he published a *Narrative of a Visit to Europe in 1851* (his *Journals of Travels in England, Holland, and Scotland* had appeared as early as 1810). He died 24th November 1864, at New Haven, where a bronze statue has been erected (1884) in the college grounds. See the Life by G. P. Fisher (1866).—His son, Benjamin (1816-85), assisted his father from 1837, in 1847 founded the Yale (since 1860 the 'Sheffield') School of Science, and was its professor of Chemistry till 1869, except in 1849-54, when he held a chair at Louisville. He was professor of Chemistry at Yale from 1854—in the college till 1870, in the medical department till his death. His researches were chiefly in applied chemistry and in mineralogy. From 1845 to 1885 he was co-editor of the *Journal of Science,* and he published very popular manuals of chemistry and of physics, and a volume on *American Contributions to Chemistry* (1875).

Silloth, a seaport and watering-place of Cumberland, on the Solway Firth, 20 miles W. of Carlisle. Prior to the opening of the railway in 1856 it was a mere hamlet, but it is now of growing importance, with good docks opened in 1857-85. Silloth, which commands a fine view, is much resorted to for sea-bathing, the climate being mild and salubrious, and considered highly favourable for those affected with pulmonary complaints. The mean annual temperature is 49° 1′, being the same as that of Worthing (q.v.) on the south coast of England, and only 1° below that of Torquay. Pop. (1861) 1521; (1881) 2116; (1891) 2600.

Silo. See Silage.

Siloam, a great rock-cut pool to the south-east of Jerusalem, with a second or lower reservoir connected with it by an aqueduct. See Jerusalem and map; and for the ancient Siloam inscription describing the making of a tunnel from a spring to the pool, found in the tunnel in 1880, see Inscriptions, Vol. VI. p. 159; Hebrew Language, Vol. V. p. 614.

Sil'ures, an ancient people inhabiting the south-east of South Wales and the adjoining English area—Glamorgan, Brecknock, Monmouth, Radnor, Hereford. They were a dark and curly-haired race, and were probably of a non-Aryan stock—Iberian or Euskarian—though ultimately Celticised in language and manners. Less civilised than their British neighbours, they were more warlike, and offered fierce resistance to Ostorius Scapula and the other Roman commanders who invaded their country. See Wales, Basques, Celts; Elton's *Origins of English History* (1882), Rhys's *Celtic Britain* (1882).

Silurian System, a name given by Murchison in 1835 from the Silures (q.v.) in South Wales, where this system is well developed. The sedimentary strata consist principally of grits, slates, dark shales, flagstones, sandstones, and conglomerates, and interbedded with these occur occasional calcareous bands, and more or less lenticular beds of limestone. The following table gives the succession of the Silurian system of Britain:

Upper Silurian....	Ludlow Group.
	Wenlock Group.
	Upper Llandovery Group.
Lower Silurian. ..	Lower Llandovery Group.
	Bala and Caradoc Group.
	Llandeilo Group.
	Arenig Group.

The strata attain a thickness of more than 20,000 feet, and have a wide distribution. In Wales the basement beds rest conformably on the upper members of the Cambrian system, while a well-marked unconformity separates the Lower from the Upper Silurian. Silurian rocks are exposed at the surface in many of our upland areas: thus, they form a large part of the high grounds of Wales, Westmorland, and Cumberland, and the major portion of the Southern Uplands of Scotland, and they likewise extend into the Scottish Highlands. In the hilly parts of Ireland they are also well developed at the surface; nor can there be much doubt that the same strata, buried under younger systems, extend throughout the larger part of the British Islands. The deposition of the Lower Silurian was marked by the appearance of considerable volcanoes in Wales, Westmorland, Ayrshire, and the south-east of Ireland.

On the continent of Europe Silurian strata have an extensive development. They occupy large tracts in Scandinavia and the basin of the Baltic, and probably continue eastwards under the great plains of northern Russia, for they crop up along the flanks of the Ural Mountains. In middle and southern Europe they rise again and again to the surface in mountain-regions, from which it may be inferred that they underlie vast areas in the surrounding low grounds. In North America Silurian rocks extend westwards from the mouth of the St Lawrence by the great lakes into the far north-west, and south-west by the Alleghanies into Alabama. As more or less isolated areas rise to the surface in the interior of the continent, it is probable that Silurian strata, concealed under younger formations, extend throughout the interior continental basin; and they reappear in the Rocky Mountains. The system has been recognised as entering into the formation of the Cordilleras of South America. Silurian strata have also been detected in the Himalayas and other parts of Asia, in Australia, and New Zealand.

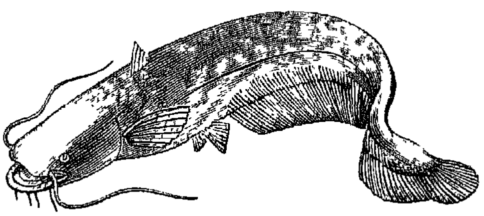
The Silurian rocks which occur in mountainous areas are usually much indurated and dip at high angles, being frequently much contorted and dislocated. In the Highlands of Scotland and in Norway they have even been subjected to such disturbance that they have over wide areas acquired a more or less schistose or foliated character. In other low-lying regions, however, as in Russia, the strata are not indurated, and occur in horizontal or gently inclined positions.

Life of the Period.—Plant-remains consist almost exclusively of seaweeds, only a few traces of land-plants having been met with. These indicate a cryptogamic flora—ferns and lycopodiaceous trees. The lower forms of animal life were represented chiefly by sponges (Amphispongia, Astylospongia, &c.). Amongst the Cœlenterata were numerous forms of graptolites and corals. The former are eminently characteristic of the Silurian, and abound in certain thin bands of black shale. Those with two rows of cells are mostly confined to the Lower Silurian, while the single-rowed graptolites are upon the whole most common in the Upper Silurian. Corals abounded—certain limestones appearing to be almost wholly made up of their remains. Some common or characteristic rugose forms were Omphyma, Zaphrentis, Cyathophyllum, &c. Prominent tabulate forms were Halysites, Favosites, &c. The living Alcyonarian corals (Heliopora) were represented by Heliolites. Crinoids or sea-lilies were very numerous—their jointed stems and arms entering largely into the composition of many of the limestones. Cystideans, which attained their maximum development in Silurian times, star-fishes, and brittle-stars appear to have been less abundant. Annelid-tracks are common on the surfaces of beds, and the filled-up burrows of sea-worms frequently occur. Now and again jaws of annelids are likewise met with, and occasionally their tubular cases (Serpulites, Spirorbis) are seen attached to shells, corals, &c. Among the most characteristic Silurian fossils were the Trilobites, which made their first appearance in Cambrian seas and reached their greatest development in the Silurian age. They lived on in much diminished numbers through the Devonian and Carboniferous periods, and became finally extinct in Permian times. Some of the more widely distributed Silurian forms are Ogygia, Trinucleus, Asaphus, Illænus, Phacops, Calymene, &c. Other remarkable Arthropods were the Eurypterids (an extinct order allied to the existing king-crabs). One of these (Pterygotus) was seven or eight feet in length. Ostracods (Beyrichia) and Phyllopods (Ceratiocaris) likewise occur in Silurian rocks. Here also we meet with the first scorpion (Palæophoneus) and the earliest insect (Palæoblattina, a form of cockroach). Various lace-corals (Fenestella) and other Polyzoa occur, but by far the most abundant forms amongst Molluscoids were the Brachiopods. Characteristic types are Discina, Orthis, Leptæna, Pentamerus, Rhynchonella, Strophomena. Lamellibranchs were much less numerous—Modiolopsis, Ctenodonta, and Orthonota are examples. Amongst Gasteropods the more common genera are Euomphalus, Bellerophon, Holopella, Murchisonia, and Pleurotomaria. The Cephalopods are well represented by straight and coiled chambered cells: amongst the former is Orthoceras, many species of which are known; the latter show such types as Cyrtoceras, Lituites, Phragmoceras, Nautilus, &c. Vertebrates make their earliest known appearance in the Upper Silurian. The remains consist of bony bucklers or head-shields of ganoid fishes (Pteraspis, Cephalaspis), the defensive spines of some cestraciont, and fragments of shagreen-like skin and plates.

Physical Conditions.—The Silurian strata appear to have been deposited chiefly in shallow seas, which here and there, however, may have been moderately deep. No certain indications of true oceanic conditions have yet been met with. During the formation of the Lower Silurian strata the entire area of the British Islands, with the exception, perhaps, of some of the Archæan tracts of the north-west, appears to have been under water. At this time active volcanoes, forming groups of islets, were scattered over the area of what is now North and South Wales, the south-east of Ireland, and southern Ayrshire. Considerable earth-movements affected the British area at the close of the Lower Silurian period—the bed of the sea being here and there elevated, so that islands of considerable size came into existence at the beginning of the Upper Silurian period. Eventually, however, a movement of depression supervened, and the islands referred to were submerged and gradually buried under the sedimentary accumulations of the Upper Silurian sea. Judging from the geographical distribution of the Silurian strata, we are led to conclude that enormous areas of what are now our continents were during the accumulation of those rocks overflowed by shallow seas. The main land-masses of the period seem to have been grouped chiefly in boreal regions and were composed essentially of Archæan rocks. In Europe and North America alike the old land-surface lay towards the north, but the great continental ridges may have risen here and there to the surface in other places so as to form groups of islands, as in Bavaria and Bohemia in Europe, and in the region of the Colorado and Park ranges in America.

The temperature of the seas was such as to allow of the migration of closely allied and apparently identical species of molluscs, crustaceans, &c. over vast regions. In arctic lands fossils occur which are met with likewise in the Silurian rocks of Wales; more than this, many Silurian species were truly cosmopolitan, ranging from the extreme north across the equator to Australia. To have allowed of such world-wide distribution the temperature of the seas must have been singularly uniform. But while not a few Silurian species were cosmopolitan, many others appear to have had a more restricted range. Thus it may be inferred that, however uniform the climatic conditions may have been, the uniformity nevertheless was only comparative, and that even in Silurian times the oceanic areas had their distinct life-provinces. It is remarkable that in the Lower Silurian of Scotland large erratic blocks of gneiss and other crystalline rocks occur, and similar blocks are met with in the Silurian strata of the Lake Superior region. It is difficult to see how such blocks could have been transported without the agency of floating ice. See also the articles MURCHISON and GEOLOGY.

Siluridæ, or CAT-FISHES, a large family of fresh-water fishes, included in the order Physostomi. The skin is naked, or equipped with some bony scutes, never with scales; the dorsal fin is short and is occasionally absent—when present it is inserted above or in front of the ventrals; there is generally an adipose fin; the maxilla is very small; the barbels are well developed. The family is represented in most parts of the world. In Europe, however, there is only one Siluroid, the Sheat-fish or Shadden (*Silurus glanis*), which occurs in some eastern and central regions—e.g. in the Danube and the Elbe. In size it sometimes approaches the sturgeon, and is a sluggish but very voracious animal, and has been the subject of many strange stories. In North America most of the common cat-fishes belong to the genus Amiurus; in tropical America the genus Pimelodus has many representatives (see CAT-FISH). In many species of Arius—a marine genus—common in the East Indies and on both coasts of Central America, the males hatch the eggs in their mouths. Species of Doras, common in South America, are remarkable for their habit of travelling from one pond to another. In northern Africa the most remarkable Siluroid is the Electric Cat-fish, *Malapterurus electricus*.



Silurus glanis.

Silver (sym. Ag; equiv. 108; sp. gr. between 10·47 and 10·57). This metal was one of the earliest known, and is of a peculiar and beautiful white colour, by which it can be distinguished from all other metals or alloys, except one or two rare metals, such as lithium and indium, which are seldom seen. Silver is harder than gold, but softer than copper. It takes a very high polish, and for this reason was sometimes used for making small mirrors by the ancient Romans. It ranks next to gold in malleability and ductility, the thinnest silver-leaf produced by hammering being only $\frac{1}{100000}$ of an inch thick; and a wire of the metal can be drawn so fine that a length of 130 yards weighs only one grain. It has been usually stated that silver has a clear ringing sound when struck, but accurate observers, like Karsten and Percy, say that, on the contrary, a bar of the metal emits a dull sound on receiving a blow. Silver conducts heat and electricity better than any other metal, for which reason it is adopted as the standard represented by 100. Its melting-point has been variously stated, but appears to be about 1904° F. (1040° C.). Silver does not suffer even from long exposure to the atmosphere, except that it readily tarnishes when sulphuretted hydrogen or animal exhalations containing sulphur are present. Both nitric and sulphuric acid dissolve silver; and aqueous hydrochloric acid, as well as a solution of common salt, converts the surface of the metal into the chloride of silver. The metal is not attacked by caustic alkalies.

Oxides of Silver.—Three compounds of silver with oxygen are known. *Argentic Oxide* or *Protoxide of Silver*, Ag_2O, is the best defined of the three. If to an aqueous solution of nitrate of silver lime-water or baryta-water be added, this oxide of silver is precipitated. The same brown precipitate is obtained if pure potash or soda be used as the precipitant. The protoxide of silver when moistened absorbs carbonic acid from the air. It decomposes and loses its oxygen at 572° F. (300° C.), and ignition takes place when it is rubbed in a mortar with sulphide of arsenic or of antimony and other easily oxidisable substances. The other two oxides of silver are the *Argentous Oxide* or *Suboxide*, Ag_4O, and the *Peroxide*, Ag_2O_2.

Sulphide of Silver, Ag_2S.—The strong affinity silver has for sulphur is seen from the readiness with which it blackens in an atmosphere containing sulphuretted hydrogen. A silver coin can be easily darkened by rubbing it with sulphur or by placing it in contact with vulcanised india-rubber, which contains sulphur. Sulphide of silver can be prepared by melting together silver clippings and sulphur in a covered crucible. It is also formed when sulphuretted hydrogen or a soluble alkaline sulphide is added to an aqueous solution of a salt of silver, the silver sulphide precipitating as a black powder. The tarnish on silver articles which from their nature cannot be easily rubbed with leather and rouge or brushed can be readily removed by an aqueous solution of cyanide of potassium; but as this salt is poisonous the article should be afterwards carefully washed. Silversmiths perfectly restore the original white colour to darkened silver objects by heating them in contact with carbonate of soda and nitre. Statuettes and other art objects in silver are frequently 'oxidised,' as it is called. This is really darkening their surface more or less by a film of sulphide produced by immersing them in a hot solution of sulphide of potassium. The prominent parts are then brightened by brushing or otherwise. The native compounds of silver and sulphur (ores) are noticed below.

Chloride of Silver, AgCl.—This salt is prepared by adding to an aqueous solution of the nitrate of silver either hydrochloric acid or chloride of sodium (common salt), when a thick, white, curdy precipitate of the chloride is thrown down. The precipitate requires to be washed and dried in the dark, and it is then an anhydrous white powder. When fused and allowed to cool it becomes waxy and hornlike, in which state it is translucent or even transparent in thin plates. In this massive condition it is still sometimes called by the old name of *horn silver* or *luna cornea*, whether native or artificially prepared. Chloride of silver is very insoluble in water, so that an extremely small proportion of silver may be detected in water by the formation of chloride. It dissolves in ammonia-water and cyanide of potassium or sodium. When a solution of chloride of silver in ammonia-water is boiled a fulminating compound is deposited; but this can be avoided by evaporating the solution at a gentle heat, by which treatment scales of the chloride separate. As commonly prepared, chloride of silver blackens by exposure to daylight. Native chloride of silver is an important ore of the metal, and is referred to below. So also are the native compounds of silver with bromine and iodine.

Cyanide of Silver, AgCy, is obtained by precipitation as a white powder when hydrocyanic acid or cyanide of potassium is added to an aqueous solution of nitrate of silver. It is insoluble in water, but aqueous solutions of ferrocyanide of potassium, hyposulphite of soda, and ammonia and some of its salts dissolve it. It forms double salts with various metallic cyanides, one of these, the *argento-cyanide of potassium*, being of great service in Electro-metallurgy (q.v.). Mr A. Wright, surgeon, Birmingham, first applied this salt to electroplating, his invention having been bought and patented by the Messrs Elkington in 1840.

Nitrate of Silver, $AgNO_3$, is one of the most important salts of the metal. It crystallises in colourless tabular plates belonging to the prismatic system, has a specific gravity of 4·355, and fuses at a low temperature, forming after solidification the *lunar caustic* used as an escharotic by surgeons. If during fusion the temperature is allowed to rise above 383° F. (198° C.) the salt is decomposed. Nitrate of silver dissolves in rather less (·783) than its own weight of water at 51·8° F. (11° C.), and is more soluble at higher temperatures. It is prepared by dissolving silver in moderately strong nitric acid with the aid of heat, and has a very bitter taste. Unless in contact with organic matter, nitrate of silver is not blackened or discoloured by the action of light. An ink for marking linen or cotton is prepared by dissolving 2 parts by weight of nitrate of silver and 1 part of gum-arabic in 7 parts of water, a little Indian ink being added. For the use of nitrate of silver in taking photographic pictures, see PHOTOGRAPHY. Black stains upon the hands or upon linen caused by nitrate of silver may be removed by a strong solution of iodide of potassium, or more efficiently by cyanide of potassium, which, however, is poisonous. When phosphorus is kept immersed in an aqueous solution of nitrate of silver the metal is reduced. This supplies a means of coating delicate objects with a film of silver. The article is dipped for a moment in bisulphide of carbon containing $\frac{1}{20}$ of its weight of phosphorus in solution. As the bisulphide evaporates, phosphorus is left in a state of fine division over the surface of the object, which is then dipped into an aqueous solution of nitrate of silver, from which silver is reduced by the phosphorus. Such objects as insects, feathers, and lace can be thus coated with silver, but adroitness is necessary, as finely-divided phosphorus takes fire spontaneously.

Sulphate of Silver, Ag_2SO_4.—This salt is formed either by adding sulphate of soda to an aqueous solution of nitrate of silver, when it is thrown down as a precipitate, or by boiling granulated silver with sulphuric acid. The process for 'parting' an alloy of silver and gold by sulphuric acid is referred to below.

Silver can be removed from old plated articles by boiling them in a menstruum of 3 lb. of sulphuric acid, 1 lb. of water, and 1½ oz. of nitrate of potash. The silver in the solution is then precipitated as the chloride, and from this the metal is recovered.

ORES OF SILVER.—*Native Silver* occurs in many forms and in numerous localities. It crystallises in the cubical system. Some specimens are of dendritic or arborescent form; others are found in laminæ or foil; others again are massive, or occur in grains or specks disseminated through veinstone of different kinds. Native silver is usually associated with other ores of the metal. All native gold contains more or less silver, and when the proportion of the latter reaches about 20 per cent. the native alloy is called *electrum*. The amount generally varies between 3 and 25 per cent., but some of the specimens of pale gold found in Transylvania contain 38 per cent. of silver. In Europe native silver has been found most largely at Kongsberg in Norway, where the mines have been worked since 1623. Most of the silver produced by these mines has been obtained in the native state. Some very heavy single pieces have been found; one in the Copenhagen Museum weighs 560 lb., but another lump was dug out nearly three times as heavy. At Freiberg in Saxony a mass weighing 140 lb. was once obtained. A mineral vein on Silver Islet, Lake Superior, contains much native silver; and at Minnesota, on the same lake, the native copper is sometimes studded with native silver in the form of lumps, or grains, or stringy pieces. Native silver is or was abundant in the great Comstock lode in Nevada, and is common in the silver lodes of Mexico, Chili, and Peru.

Argentite, Silver Glance, Vitreous Silver, Sulphide of Silver.—A large amount of silver is obtained from this ore, which is abundant in Mexico and in the deep part of many mines in Chili. It occurs in the Comstock lode, Nevada, and sparingly in some European mines, including some in Cornwall. Argentite crystallises in the cubical system, and when pure contains 87 per cent. of silver and 13 of sulphur.

Stephanite, Brittle Silver Ore, Sulph-antimonite of Silver, is another important ore of silver. It is found accompanying other silver ores in a number of the well-known metalliferous mines of Europe, including those at Freiberg in Saxony, Andreasberg in the Harz, and in Bohemia and Hungary. It is also one of the minerals mined in Mexico and Peru. It crystallises in the prismatic system, and when pure contains 71 per cent. of silver, 13 of antimony, and 16 of sulphur.

Pyrargyrite, Dark Red Silver Ore, Sulph-antimonite of Silver.—This ore is found in the same European localities as Stephanite, and likewise occurs in Mexico, Chili, Idaho, and Nevada. Small quantities of it have occasionally been got in Cornwall. Crystallising in the rhombohedral system, it often forms like Proustite, to be presently referred to, a very beautiful mineral of a blood-red colour, which, however, darkens by exposure to light. When pure, pyrargyrite contains 60 per cent. of silver, 22 of antimony, and 18 of sulphur.

Proustite, Light Red Silver Ore, Sulph-arsenite of Silver, is, like the last, a rich silver ore, and crystallises in the same system. It is found in some of the same mines in Saxony and Bohemia, and in one or two places in France and Spain. Some of the silver-mines in Mexico, Chili, and Nevada are also localities for it. When pure it contains 65½ per cent. of silver, 15 of arsenic, and 19½ of sulphur.

Stromeyerite, Sulphide of Silver and Copper.—The cupriferous silver ores of Chili are said to consist chiefly of this mineral, but it is usually so intimately mixed with felspathic vein-stuff that it is difficult to separate pure pieces. It is also found in Arizona, California, Silesia, and Siberia. In its pure state its composition is silver 53·1, copper 31·1, and sulphur 15·8 per cent.

Chlorargyrite, Cerargyrite, Kerate, Horn Silver, Chloride of Silver.—The most important localities for this valuable ore are Nevada (White Pine District), California, Idaho, Arizona, British Columbia (Fort Hope), certain districts in Mexico, Chañarcillo in Chili, and in the Silverton district and Barrier Ranges in New South Wales. But it also occurs, though for the most part sparingly, at Kongsberg in Norway, Allemont in France, the Saxon and Harz mining districts, and in one or two Cornish mines. It crystallises in the cubical system, but is usually massive with a wax-like appearance. It is malleable and sectile. This ore when pure contains 75 per cent. of silver and 25 of chlorine.

Embolite, Chloro-bromide of Silver, is the chief ore obtained in the mines of Chañarcillo in Chili, but it is believed that much of the ore called chloride of silver is really this mineral. Embolite contains from 61 to 68 per cent. of silver with variable proportions of chlorine and bromine.

Bromite, Bromyrite, Bromargyrite, Bromide of Silver.—This is the chief constituent of a silver ore found in a few Mexican mines, and it also occurs in Chili. The pure ore consists of 57½ per cent. of silver and 42½ of bromine.

Iodite, Iodyrite, Iodargyrite, Iodide of Silver, is a comparatively rare silver ore, occurring in a few of the Mexican and South American mining districts; also in Arizona and Spain.

Arquerite is a native silver amalgam containing 86½ per cent. of silver and 13½ of mercury. It is the principal ore of the mines in the Arqueros district near Coquimbo in Chili, but it is also found with alluvial gold in British Columbia. Other silver amalgams are found in some European mines as well as elsewhere.

METALLURGICAL PROCESSES.—Owing to its high value and the many different ways in which silver occurs in nature, the metallurgical processes in use for the extraction of the metal from its ores are perhaps more varied than those employed in the case of any other metal. If it were obtained only or chiefly from comparatively rich or pure ores the state of matters would be different, but silver is most largely extracted from ores in which the metal in some form is minutely and sparsely disseminated through an earthy or rocky matrix, or from ores of common metals in which it is present in only very small proportion, as in the case of argentiferous lead and copper ores. More than one-half of all the silver produced is obtained from lead ores. The scarcity or abundance of fuel is an important question in determining what process can be most economically employed. The three important methods of separating silver from its ores are (1) by forming an amalgam of silver with mercury, from which the latter is afterwards separated by distillation; (2) by converting the silver in sulphuretted ore or regulus into a soluble salt, and from its solution precipitating the silver by metallic copper or iron; (3) by forming a rich alloy with lead, as through the smelting of silver ores with galena or other lead ore, from which the silver is afterwards separated by cupellation.

Amalgamation Processes.—The Mexican or Patio amalgamation process, invented by Bartholomé Medina about the middle of the 16th century, has been practised with but little alteration down to the present time. Silver is one of the metals which mercury unites with at common temperatures, but the amalgamation proceeds more quickly with the mercury at or near its boiling-point. Mexican silver ores consist of sulphides, chloride, chlorobromide, and native silver generally disseminated through rocky gangue or other minerals. The ore, first broken into small pieces by stamps or edge stone mills, is most frequently ground in Mexico in a circular trough (*arrastre*), in some cases 9 feet in diameter and 1 foot deep, with a flat bottom formed of hard stones. In the centre revolves a vertical shaft on which are fixed four arms, each carrying a heavy stone by which the ore is reduced to a fine powder, or rather, as water is used, to a fine mud.

In the Patio process, which is best suited for sulphuretted silver ores, the materials used besides the ground ore are *magistral* (sulphide of copper roasted, so as to produce as much sulphate as possible), common salt, and mercury. The ore, at first a fine mud, is partially dried and worked into flat circular heaps, which, though sometimes smaller, generally contain from thirty to sixty tons. Salt-earth is then added in such quantity as will yield chloride of sodium amounting to fully six per cent. of the ore, a limited quantity of water being used. After a mixture of this salt with the ore is made, the heap is made circular and trodden by horses for two hours, the mixture being turned over by men in the middle of the operation. The next step is to add about two per cent. of *magistral*, which is spread over the ore and incorporated with it also by the feet of horses. If the ore under treatment contains about sixty ounces of silver per ton, then mercury to the extent of 24 lb. per ton is spread over the heap in small globules by pressing it through linen bags. Only about two-thirds of this mercury is, however, added in the first instance, and the mass again trodden for two hours by horses. The ore in the heap, now called a *torta*, is next turned over by men, and horses once more trot over it for a rather longer time. After this the mixed mass of ore, mercury, and other materials is left to rest for a day, when horses again travel over the torta. It is now time to add the second portion of mercury, and again to turn over the ore mixture. Further treading by horses and turning over by men follow at intervals of days, the completion of the amalgamation process taking about a fortnight in summer and considerably longer in winter. The dry amalgam produced by the above operations now receives an addition of mercury to render it liquid enough to admit of its being separated from the slime by washing.

For what is called the *Cazo* or *Caldron process*—i.e. the hot amalgamation method as practised to some extent in Mexico, but more generally in South America—the suitable ores are those containing native silver or such as consist of silver in union with chlorine, bromine, or iodine. It is unsuited for sulphuretted ores. After having been ground, dressed, and washed, the ore is put into a caldron with a thick copper bottom, along with water to form a thin mud. A fire is then lighted beneath it, and just before the liquid stuff begins to boil common salt to the amount of about one-sixth part of the weight of the ore is added, and enough mercury put in, but not all at once, to form a soft amalgam. The liquid is constantly stirred by revolving arms on an upright shaft with copper blocks attached to them. In about six hours the operation is completed, and the amalgam is then separated from impurities. Care is necessary in this process not to use excess of mercury, which should not be more than four times that of the silver by weight. A greater quantity produces adhesion of the silver amalgam to the copper, and sometimes a copper amalgam is formed if the blocks rotate too slowly.

The amalgam, after being subjected to filtration through canvas, is distilled in an iron bell-shaped vessel or cylindrical retort, by which the mercury is expelled as vapour and the fumes condensed in a trough containing water. The silver remains in the retort, and is afterwards cast into bars.

The great silver-producing region of the United States was only discovered so recently as 1859. The lodes occur either in the Rocky Mountains or to the west of them, in the states of Montana, Idaho, Nevada, California, Colorado, Arizona, and in Utah and New Mexico. There is great variety both in the kind of ores which are found and in their richness in silver. Much of the ore raised contains both gold and silver.

Argentiferous lead ores consisting of earthy carbonates and sulphates as well as galena are found largely in Utah. The amount of silver in these ranges from 10 to 150 ounces per ton, but in some places the minimum quantity is 70 ounces. These ores are smelted at various works, and the resulting argentiferous lead is desilverised by the zinc process (see LEAD). Sulphuretted silver ores prevail in the United States, and these require to be roasted in furnaces along with common salt to drive off the sulphur and to form the silver into a chloride. Such ores are previously crushed by stamps or rollers in the dry state, but the more easily decomposed silver ores are crushed wet. What is called the *Pan Amalgamation Process* is that most largely practised in the silver-works of these western states. This method is founded on the Cazo process above described, an iron pan being used instead of a copper vessel. These pans, which were introduced soon after the silver ores of Nevada and adjoining states began to be worked, are tubs 5 or 6 feet in diameter, and generally made entirely of iron. Each has a vertical shaft passing up through the centre, upon which is fitted a revolving muller with iron shoes, which come almost close to dies fixed to the bottom, and between which the pulp passes. This shaft is kept in motion by strong spur gearing, and there is usually a double bottom to the pan for heating by steam. Different pans are in use, but they vary more in detail than in principle. Fig. 1, from Egleston's *Metallurgy*, shows the Horn pan in section. These vessels are charged half-full of crushed ore and water, and they are designed with the intention of uniting as far as possible a grinding with a stirring surface. Common salt, sulphate of copper, and sometimes other chemicals are added to the charge. A pulp is produced just thick enough to allow the muller to rotate, and the temperature of the charge is raised by steam to from 160° to 200° F. The necessary quantity of mercury is added, and the pulp containing the amalgam is ready to be removed after the charge has been in the pan five hours. The amalgam is then cleaned and strained, and the mercury separated from the silver by distillation in a cast-iron retort.

Freiberg Processes.—The Barrel Amalgamation Process, formerly practised with much success at Freiberg in Saxony, is or very recently was in use at some silver-extraction works in America. The Freiberg ores are complex. Certain lodes contain various sulphuretted silver ores in quartz vein-stuff, but other lodes yield along with these argentiferous galena, zinc-blende, copper and iron pyrites, and other metalliferous minerals in a vein-stuff of baryta, spathic carbonates, &c. These ores were pulverised and so mixed that the poorer class contained 30 or 40 ounces of silver per ton, and the richer class three or four times as much. An ore of this nature is roasted with common salt to convert the sulphide of silver into chloride, after which it is finely ground and placed in the amalgamating casks along with water, scrap-iron, and mercury. The iron reduces the silver to the metallic state, and it then combines with the mercury to form an amalgam which, when separated from the residues, is distilled in iron retorts. This is a more perfect system than the Mexican method, but there is a considerable expense for fuel. Fig. 2 shows the arrangement of rotating barrels used in this process.

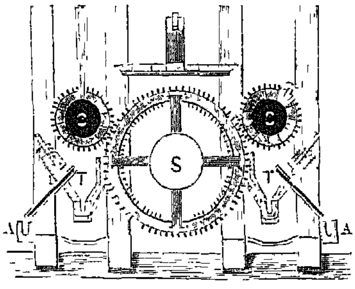

Fig. 2.—Vertical Section of Amalgamating Apparatus: C, C, oak barrels; S, toothed wheel for setting the barrels in motion; A, A, troughs for amalgam; T, T, troughs for residues.

At the present time silver is obtained at the Freiberg works by the smelting of argentiferous lead and copper ores in a Pilz blast-furnace, an illustration of which is given in the article **Lead**. The charge is composed of lead ores, zinc-blende, and pyritic ores, some of which are highly siliceous. This ore-mixture contains the following metals, the average percentage of each being—lead 23, zinc 13, copper 3, and silver ·08 to ·60, together with sulphur and quartz gangue. The ore is first roasted in a reverberatory furnace, and then smelted in the Pilz furnace along with slags and various residues rich in silver. Coke is used as fuel, and the products of the furnace are lead containing a variable amount of silver, a regulus of lead and copper with from 0·1 to 0·2 per cent. of silver, and a slag containing lead with sometimes ·04 per cent. of silver. The lead in the regulus is separated from the copper by another smelting. Most of the silver is retained by the lead, and is recovered from it by Pattinson's desilverising process and subsequent cupellation. See **Lead**.

Augustin Process.—This and the next are wet processes for the extraction of silver. When certain argentiferous ores or products are roasted with common salt the chloride of silver is formed. This chloride is soluble in a strong solution of common salt, and from the solution so formed metallic silver is precipitated by means of copper. An equivalent quantity of copper chloride is at the same time formed, from which metallic copper is in turn precipitated by iron. Sulphuretted ores or compounds are used in this process.

Ziervogel Process.—No simpler process is known for the extraction of silver from argentiferous copper pyrites (which nearly always contains iron) or of an ore in which it is an important constituent. The method is based upon the fact that sulphide of silver contained in the ore, or matt derived from it, is converted into a soluble sulphate by very careful roasting. By the reactions in the furnace sulphate of iron is first formed, then sulphate of copper, and finally, by the decomposition of these, sulphate of silver, which is readily dissolved out of the roasted ore by hot water. The silver is then precipitated from the solution by copper.

Smelting of Silver.—At Kongsberg in Norway, and at Wyandotte in Michigan, silver ores, consisting chiefly of native silver with other minerals in a rocky matrix, are smelted in furnaces. At the former locality, by the addition of iron pyrites to the ore, a regulus consisting chiefly of sulphide of iron and some sulphide of copper is first formed. When in the molten state this is mixed with one-third of its weight of lead, which, after taking up most of the silver, separates by its own weight. From this silver-lead the silver, amounting to 5 per cent. of the alloy, is separated by cupellation. At Wyandotte a slightly richer silver-lead is produced which is also cupelled.

Combined lead and silver smelting, as conducted in Great Britain from native ore (argentiferous galena), is described under LEAD. There are no silver ores properly so called produced in the United Kingdom, but foreign ores are smelted along with lead ores or rich lead slags.

Liquation Process.—Silver can be separated from argentiferous copper by this process, which consists in heating a fused mixture of the copper with a large excess of lead to a temperature above the melting-point of the latter, but below that of the copper. In this state of matters the lead liquates or sweats out of the mass, carrying with it the greater part of the silver which the copper contained. This silver can then be extracted from the lead by cupellation.

Cupellation.—This process consists in melting lead rich in silver on the hearth of a small furnace, and blowing air over its surface, the oxygen of which, under the influence of the heat, rapidly converts the lead into litharge or plumbic oxide. Fused litharge has the property of dissolving the oxides of some other metals, such as copper, zinc, tin, antimony, &c. Silver, however, is not oxidised by this treatment. The result of the operation is that the whole of the lead put in the furnace, together with small quantities of other oxidisable metals (present as impurities), are removed as oxides, and the silver is left on the bed of the furnace. In the English cupellation-furnace the bed or hearth is movable, and is formed of an oval iron frame or test rammed full of powdered bone-ash. The German cupellation-furnace (shown in fig. 3) is of larger capacity than the English, and has a movable domed cover constructed of iron. The diameter of this furnace is about 10 feet, and the hearth is covered with marl. These furnaces differ only in details and in the way in which they are charged. In the United States what is termed a Steitz water-back cupel—a hollow casting through which water flows—is used in the first stage of cupellation.

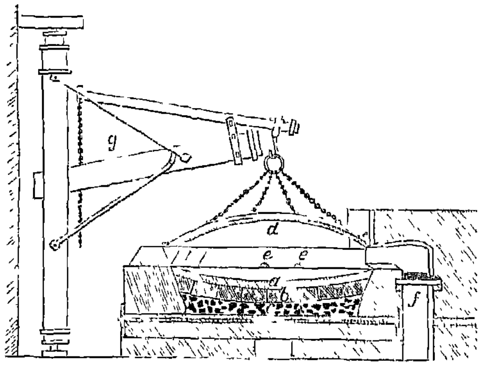

Fig. 3.—Silver Cupellation-furnace : *a*, hearth of marl or clay ; *b*, bricks ; *c*, bed of slag ; *d*, movable cover ; *e*, *e*, tuyeres connected with bellows ; *f*, fireplace ; *g*, crane for lifting cover.

There are three processes for *separating silver from gold* practised on a large scale. One of these is a very old method. It is called 'parting' by nitric acid. The alloy, which may consist of one part by weight of gold to two of silver or of one of the former to three of the latter, is melted and granulated—i.e. formed into small beads. It is then boiled (in platinum or earthenware vessels) with nitric acid, of 1·4 sp. gr. and an equal bulk of water, for several hours, till the silver is almost all converted into nitrate, the gold forming the residue after the dissolved silver is removed. To this solution of nitrate of silver common salt is added to precipitate the silver as chloride, from which the metal is reduced by the action of granulated zinc and weak sulphuric acid. The silver is then washed, pressed, dried, and melted, producing bars almost pure from the alloys generally treated.

Another method of 'parting' is by boiling the alloy in concentrated sulphuric acid. Auriferous silver, either granulated or in bars, is placed in cast-iron pots along with sulphuric acid, which is cautiously raised to the boiling-point. The silver, if it does not much exceed 200 lb. in weight, is dissolved in about eight hours, but sooner if granulated. The gold falls down as a sediment, and the sulphate of silver is drawn off by a platinum siphon or otherwise. The solution of sulphate of silver is then diluted with water, and the metal precipitated by scrap-iron. Impurities in the alloy sometimes render the sulphuric acid method of parting troublesome.

Separation of silver from argentiferous gold is now effected by chlorine, a method patented by F. B. Miller in 1867, and soon afterwards used at the Sydney mint and at other places. Gold, to the amount of 600 or 700 ounces, is melted in a clay crucible, and a little melted borax thrown in. Chlorine gas is then admitted through a suitable pipe, the end of which almost reaches the bottom of the crucible, so that the gas is forced to bubble up through the molten gold. At first volatile chlorides of some of the baser metals, which may be present in very small quantity in the alloy, escape through holes in the cover of the crucible, but the chloride of silver does not. Chlorine is supplied till it is found that no more is absorbed, which shows that practically all the silver has been changed into chloride. When this is the case the crucible is allowed to cool sufficiently to allow the gold to solidify, and the red-hot liquid chloride of silver is then formed into slabs in moulds. This chloride generally contains 2 per cent. of gold, but it is eliminated by adding metallic silver, with which the gold forms an alloy. From the slabs of chloride of silver the metal is reduced by using them as one of the elements of a galvanic battery.

The production of silver has increased enormously since the discovery of the rich deposits in the western states of North America, the development of which may be said to have begun with the surface-workings of the Comstock lode, Nevada, in 1859. But in 1861 the yield of the United States was still comparatively small, amounting in value to not more than £400,000. In 1871 it had risen to £4,600,000 ; in 1881 the value of the production was £8,600,000 ; and in 1889 it reached the yearly total of £12,929,000. Colorado and Montana are now the great silver-producing states. The director of the United States mint gives the value of the silver production for 1889 in the following countries: Mexico, £11,103,400 ; Chili, Bolivia, and Peru together, £4,085,000 ; European countries, £2,136,000 ; and he makes out the total production of the world in that year to be £32,583,000. (The annual produce of the silver districts in the Barrier Range region, New South Wales, now amounts in value to nearly £2,000,000. The silver district of Zeehan, on the west coast of Tasmania, from which in 1891 galena ore containing 110 ounces of silver per ton reached England, promises to increase the world's supplies.) Mr J. A. Phillips estimated the annual yield of all countries in 1865 as 48,204,000 ounces, the value of which would be about £12,051,000. The great additions to the supply of silver since 1871 have lowered the value of the metal. It had long stood at 5s. per ounce, or varied only within narrow limits; but the price began to fall in 1873, and decreased gradually till 1888, in which year, and for several years after, the average value per ounce was 3s. 7d., varying only a fraction of a penny from day to day.

The amount of silver consumed for various purposes in the industrial arts must be very large. Besides its use in the coinage of all civilised nations, it is extensively employed for plate, jewellery, and watch-cases, and for electroplating articles of German silver and Britannia metal. Silver compounds are used in photography, in glass-staining, and in several chemical preparations, including marking-ink and hair-dyes. It seems to have been a favourite metal with the great nations of antiquity, personal ornaments found in Egypt, as well as ancient Greek and Roman statuettes, vases, dishes, coins, and other objects made of silver being among the treasures of the chief national museums in Europe. Like gold, silver is too soft to be used alone for vessels, jewellery, or coin, for which reason it is usually alloyed with copper. English 'standard silver' is composed of 925 silver and 75 copper. Of this alloy the silver coins and 'hall-marked' silver-plate of Great Britain is made. The alloy used for all silver coins in the United States, and major silver coins in France and Austria, is 900 silver and 100 copper or other inferior metal. *Further references to silver will be* found in the articles on Alloy, Assay, Bimetallism, Chasing, Filigree, Embossing, Hall-marks, Mining, Mint, Mirror, Numismatics, Electro-metallurgy, Metal-work, Photography, and Repoussé.

Silverfish, a name given to the Atherine (q.v.) and to artificially bred Goldfish (q.v.).

Silverton, the centre of a mining district in the extreme west of New South Wales, only 18 miles from the border of South Australia and more than 800 W. by S. from Sydney. It is connected with the railway system of South Australia. Silver (principally), copper, tin, and gold are mined in the district to the annual value of 1¾ million sterling. The town has stores, churches, banks, and a brewery. Broken Hill, one of the largest silver mines in the world (see NEW SOUTH WALES), is 17 miles SE. of Silverton.

Silvester. See SYLVESTER.

Simancas, a village of Spain, 7 miles SW. of Valladolid, where the national archives of Spain have been kept since the reign of Philip II. (1563). There are more than 30 million documents in all (see BERGENROTH). Pop. 1258.

Simarubaceæ, a natural order of trees and shrubs, with alternate, generally compound leaves, without stipules; regular, generally hermaphrodite flowers. The species are not numerous; they are found in the tropical parts of Asia, Africa, and America. The whole order is characterised by great bitterness, and several of the species are used as tonics in dysentery, &c. Quassia (q.v.), Bitterwood (q.v.), and Ailanto (q.v.) belong to it. Simaruba is itself a genus with several species, all belonging to tropical America.

Simbirsk, a town of Russia, stands on the right bank of the Volga, 350 miles SE. of Nijni-Novgorod. It has two Greek cathedrals, a large trade in wheat, wool, fruits, and potash, and a famous annual fair. The town is new, having been rebuilt since its destruction by fire in 1864. Pop. 39,047.—The *government* has an area of 19,105 sq. m. and a pop. (1885) of 1,527,762.

Simcoe, LAKE, in Ontario, between Georgian Bay and Lake Ontario, 30 miles long and 18 broad.

Simeon, CHARLES, an eminent evangelical preacher, was born at Reading in Berkshire, September 24, 1759. He was educated at Eton and King's College, Cambridge, was elected to his life-long fellowship at his college in January 1782, that same year took orders, and immediately after was appointed Perpetual Curate of Trinity Church, Cambridge, an office which he held till the close of his life, November 13, 1836. As early as twenty he had been converted through reading Bishop Thomas Wilson's book on the Lord's Supper, and as a preacher he was distinguished for an impassioned evangelicalism that at first aroused a bitter and protracted opposition. But he made many converts, and came to exercise an enormous influence not only in Cambridge, but all over England. He took a foremost part in the work of founding the Church Missionary Society, and it was mainly his influence that sent the sainted Henry Martyn to India. Simeon paid several visits to Scotland, first in 1796, when he preached freely in the pulpits of the Church of Scotland—the Moderate majority in the General Assembly prevented this on his second visit in 1798—rode over a great part of the country and climbed Ben Lomond with James Haldane, the pair consecrating themselves anew to God at the top. Simeon's conversation-circles at Cambridge were famous in his day, and his old age was untroubled and full of honour. His influence long survived his death by means of the society he established for purchasing advowsons. Simeon's *Horæ Homileticæ* (17 vols. 1819-28; new ed. 21 vols. 1832-33) contain as many as 2536 sermon outlines. See the *Memoirs* by the Rev. W. Carus (1857), *Recollections of Simeon's Conversation Parties* by Abner W. Brown (1862), and the Study by H. C. G. Moule (1892).

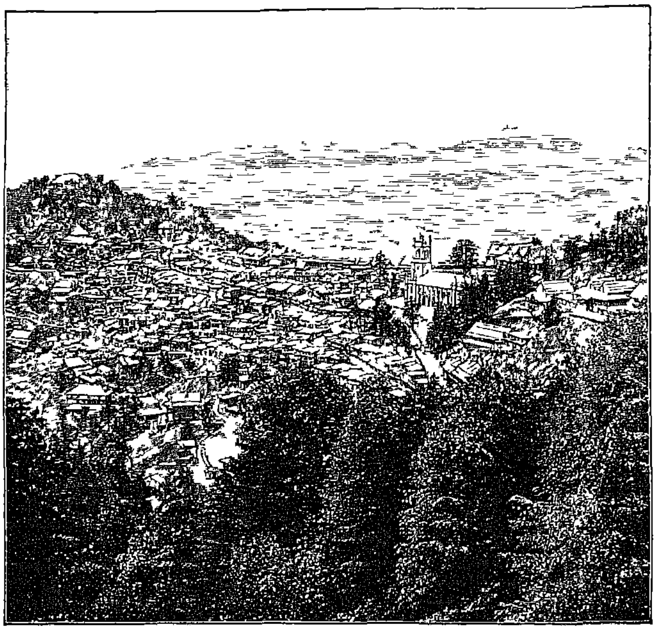
Simeon Stylites. See STYLITES.

Simferopol, a town of Russia, stands in the Crimea, 50 miles by rail NE. of Sebastopol, and has extensive gardens and vineyards. Pop. (1866) 16,550; (1885) 36,503.

Simia, the Latin name for an ape or monkey, and used by Linnæus in an almost equally wide sense, of which such current expressions as 'Simian tricks,' 'Simian language,' are a reflection. Technically, however, Simia is now reserved for the genus to which the Orang-outang (*S. satyrus*) belongs. Simiidæ includes the Anthropoid Apes: Simiinæ, the higher of the two sub-families of Simiidæ, comprising the gorilla, chimpanzee, and orang.

Simile. See METAPHOR.

Simla, a British sanatorium, the headquarters of the British government in India during the hot months of summer, stands on the southern slopes of the Himalayas, in a beautiful situation, 170 miles N. of Delhi. Its first house was built in 1819, and it was first visited officially by the Indian government in 1827, having since 1864 been regularly made its headquarters every summer. There are here two viceregal residences (the newer one built in 1886), handsome government buildings (1884), a fine town-hall (1886), several European schools, and various public institutions. Pop. (1881) 14,848 in winter, and considerably more in summer.—The *district* has an area of 81 sq. m. and a pop. (1881) of 42,945.—The name Simla Hill States is given to twenty-three native states, all small, in the neighbourhood of Simla. Their united area is 6569 sq. m. and pop. (1881) 502,853.



General View of Simla.

Simms, William Gilmore, American author, born at Charleston, South Carolina, April 17, 1806, at first was placed with a druggist there, but at eighteen began the study of law, though he scarcely practised. His earliest volume, *Lyrical and other Poems*, was published in 1827. In 1828 he became editor of the *City Gazette*, which opposed nullification and died in 1833. Meanwhile he had published *The Vision of Cortes* (1829); *The Tri-colour* (1830); and in 1832 *Atalantis, a Story of the Sea.* From this time he poured out rather than wrote poems (perhaps the best *Southern Passages and Pictures*, 1839), novels (among them *The Yemassee, The Partisan,* and *Beauchampe*), histories, and biographies in rapid succession, almost till his death, on 11th June 1870. His style is crude but vigorous, and his writings display strong imagination and many of the gifts of the born story-teller. An illustrated edition of his works in 17 vols. appeared at New York in 1882-86. There are Lives by Cable (1888) and Professor W. P. Trent (in 'American Men of Letters' series).

Simnel, Lambert. See Henry VII.

Simois. See Troy.

Simon, Jules, French statesman, economist, and author, was born at Lorient (Morbihan), 31st December 1814. He received the names of Jules François Simon Suisse, but on reaching manhood chose the designation of Jules Simon only. After a brilliant educational career, he succeeded Victor Cousin (whose ardent disciple he was) as lecturer on philosophy at the Sorbonne in 1839. He was returned to the Chamber of Deputies for the department of the Côtes-du-Nord in 1848, and took his seat with the Moderate Left. He refused the oath of allegiance to the empire, and by the year 1869 had become one of the most popular chiefs of the Republican party. He was minister of Public Instruction in the Government of National Defence; but in 1873 his measures dealing with secondary education were violently opposed by the clericals, and he resigned. He now became leader of the Republican Left. In 1874 he assumed the direction of the *Siècle* newspaper; in 1875 he was elected a life-senator; and in 1876 he was appointed prime-minister, taking the portfolio of the Interior. President Macmahon and the Right, however, resented his liberal attitude towards the press, and he forthwith resigned. M. Simon pronounced the funeral oration on M. Thiers. He always showed himself a consistent advocate of Free Trade, and took a prominent part in the revision of the Constitution. Subsequently his Republicanism developed a more conservative character, and he opposed M. Jules Ferry's bill for the expulsion of the religious orders. In 1880 the French Academy elected him a member of the new Supreme Educational Council, and two years later he was elected permanent secretary of the Academy of Moral and Political Sciences. He attended the great Labour Conference at Berlin in 1890. Besides editing Descartes, Bossuet, Malebranche, and Antoine Arnauld, with valuable introductions, and contributing to the *Revue des Deux Mondes* and other periodicals, M. Simon is the author of *Histoire de l'École d'Alexandrie* (1844–45); *La Liberté de Conscience* and *La Liberté* (1859); *La Religion Naturelle* (1856); *L'Ouvrière* (1863); *L'École* (1864); *Le Travail* (1866); *La Politique Radicale* (1868); *Souvenirs du 4 Septembre* (1874); *Le Gouvernement de M. Thiers* (1878); *Dieu, Patrie, Liberté* (1883); *Une Académie sous le Directoire* (1885); *Mémoires des Autres* (1889); and three volumes respectively entitled *Thiers, Guizot, Remorgat; Mignet, Michelet, Henri Martin;* and *Victor Cousin.*

Simon, Richard, the father of biblical criticism, was born at Dieppe, May 13, 1638. He entered the Congregation of the Oratory in 1659, but soon after withdrew, to return in the later part of 1662. He was sent first to lecture on philosophy in the college of Juilly, but was afterwards appointed to catalogue the oriental MSS. in the library of the Order at Paris. His criticisms upon Arnauld's *Defence of the Perpetuity of the Faith in the Blessed Eucharist* caused great displeasure among the Port-Royalists, and his imprudent meddling with another controversy brought upon his head the wrath of the Benedictines. The scandal occasioned by the appearance of his *Histoire Critique du Vieux Testament* (1678) led to his again withdrawing from the Oratory and retiring to Belleville as *curé.* In 1682 he resigned his parish, and lived in literary retirement at Dieppe, Paris, and again at Dieppe, where he died April 11, 1712. Few writers of his age played so prominent a part in the world of letters, and especially in its polemics. There is hardly a critical or theological scholar among his contemporaries with whom he did not break a lance—Weil, Spanheim, Le Clerc, Isaac Voss, Du Pin, Jurieu, and Jurieu's great antagonist, Bossuet. His *Histoire Critique* (suppressed through Bossuet's influence, and only printed entire at Rotterdam in 1685) anticipates the most important conclusions of all the later rationalistic scholars of Germany, and also their method of investigation, and, indeed, is the first work which treated the Bible from the point of view of a literary product. For example, he disproves the Mosaic authorship of the Pentateuch, assigning its composition to the scribes of the time of Ezra. Other writings of Simon's are *Histoire Critique du Texte du Nouveau Testament* (Rotterd. 1689); and *L'Histoire Critique des Principeaux Commentateurs du Nouveau Testament* (Rotterd. 1693), in which he assails the theology of the Fathers, and particularly that of Augustine, as a departure from the simple and less rigid doctrines of the primitive church. Among the Fathers his most esteemed authority was Chrysostom. Bossuet replied to this last work by his *Defense de la Tradition et des Saints Pères.* Simon frequently published under assumed names—as his *Dissertation Critique* on Dupin's *Library of Ecclesiastical Writers*, under the name of Jean Reuchlin; a work, *Histoire Critique sur la Creance et des Coutumes des Nations du Levant*, under the anagram of Monis; and a *Histoire de l'Origine et du Progrès des Revenus Ecclesiastiques*, under the name of Jerome Acosta.

See the Life by K. H. Graf in *Strassburger theolog. Beitrage* (1847); A. Bernus, *Richard Simon et son Histoire Crit. du V. T.* (Laus. 1869), and the same scholar's *Notice Bibliographique* (Basel, 1882).

Simonides, a celebrated Greek lyric poet, was born at Iulis, in the island of Ceos, in the year 556 B.C. He repaired to Athens on the invitation of Hipparchus, and after his death took up his residence in Thessaly, under the patronage of the Aleuadæ and Scopadæ, who appear to have treated him in a very niggardly fashion. Shortly before the invasion of Greece by the Persians he returned to Athens, and devoted his poetic powers to celebrating the heroes and the battles of that momentous struggle in elegies, epigrams, and dirges. He carried off the prize, even from Æschylus, for the elegy on the heroes that fell at Marathon. He won as many as fifty-six times in these poetical contests. He spent his last ten years at the court of Hiero of Syracuse, where he died in 468. Simonides appears to have scandalised his contemporaries by writing for hire; and his great rival Pindar accuses him, apparently not without good reason, of excessive avarice. He brought to perfection the elegy and epigram, and excelled in the dithyramb and triumphal ode; he seems also to have invented the art of artificial memory. The characteristics of his poetry are sweetness (whence his surname of *Melicertes*), polish combined with simplicity, genuine pathos, and power of expression, although in originality he is much inferior to his contemporary Pindar. The best editions of his fragments are those of Schneidewin (1835) and Bergk (*Poetæ lyrici Græci*, vol. 2)—Simonides of Ceos must be carefully distinguished from the iambic poet SIMONIDES of Amorgos, who flourished about 660 B.C.

Simon Magus (‘Simon the Magician’), the wicked sorcerer who thought that the gift of God might be purchased with money, and for this was excommunicated by Peter. The word Simony (q.v.) is derived from his name. When first introduced in Acts, viii. 9-24, Simon, apparently about 37 A.D., had already for a long time been a commanding personality in ‘the city’ of Samaria through his sorceries. Giving himself out to be ‘some great one,’ he had induced the people ‘from the least to the greatest’ to call him ‘that power of God which is called Great.’ Simon and the Samaritans had believed and were baptised under the ministry of Philip the Evangelist; and when the apostles Peter and John conferred on Philip's converts the gift of the Holy Ghost (including apparently the gift of tongues) Simon, hoping for new magical powers, went to the apostles and offered money that he might be enabled to confer the same gift. Peter's reply is known; Simon, rebuked, was submissive, and here the narrative of the Acts (written probably before the end of the 1st century) leaves him. But his penitence was only temporary. Justin Martyr says Simon afterwards went to Rome in the reign of Claudius as a wonder-worker and was reckoned a god, having a statue erected to him by the senate and people with the inscription ‘To Simon the Holy God.’ Justin, himself a Samaritan, adds that ‘almost all the Samaritans’ and ‘a few even of other nations’ worshipped Simon as the ‘First God,’ and a woman Helena, who went about with him and had formerly been a harlot, they adored as his ‘First Idea’ Irenæus follows Justin in the main, and adds that Simon professed to have appeared among the Jews as the Son, in Samaria as the Father, and to other nations as the Holy Spirit. From Simon, according to Irenæus, ‘all sorts of heresies’ derived their origin, including Antinomian doctrines. His followers worshipped images of Simon and Helena as Zeus and Athene. Hippolytus, who quotes much from Simon's work *The Great Announcement*, says that Simon encountered Peter at Rome, that he ordered his followers to bury him, promising to rise the third day, but that he never rose. Origen questions whether in his time there were more than thirty Simonians in the whole world. In the pseudo-Clementine *Homilies* and *Recognitions* (in their present form not older than the 3rd century) Simon comes into frequent conflict with Peter at Cæsarea, Antioch, and elsewhere.

Baur in 1831 was the first to observe the indisputable fact that in some portions of these books it is the apostle Paul who is caricatured under the guise of Simon—portions he believed to come from 1st-century Ebionite sources. Others of the Tubingen school went further and traced the whole story of Simon to the antipathy of the Jewish Christians against the apostle Paul, whom they regarded as a pretender (the false as opposed to the true Simon), a ‘Samaritan,’ a libertine, and a bewitcher of men. Now, however, it is generally agreed that some facts regarding Simon must be accepted as historical, and that likely enough a pseudo-Messiah named Simon appeared in Samaria in the fourth decade of the 1st century. Perhaps Klostermann and Wendt are right in holding that the ‘power of God which is called Great’ (Gr. *Megalē*) ought to be interpreted according to the Samaritan word *Megala* (‘Revealer’). Simon's ‘revelation’ or new religion had apparently for its main articles a doctrine of the essential oneness of many widely different cults—hence the attempted fusion of Baal, Zeus, the Father, the Son, the Holy Spirit—and a ‘syncretistic-gnostic’ conception of the world and its creation, together with ethical Antinomianism.

But it is obvious that the story of Simon has received accretions from a variety of extraneous sources. Thus, Justin was wrong about Simon's statue at Rome, the inscription he quotes being almost certainly identical with a dedication (still extant) by a private individual to Semo Sancus, a Sabine deity. The statement of Irenæus that Simon and Helena (called in the Clementines *Selēnē*, ‘the moon’) were worshipped under the images of Zeus and Athene may rest on a misapprehension of the Syrian Baal and Astarte worship, or on a misunderstanding of the Semitic word *Shem* or *Sem* (‘name’). Further, no one now believes that *The Great Announcement* cited by Hippolytus as Simon's dates from so early a period. Opponents have mixed him up with other sorcerers of Cyprus, Cæsarea, and Rome; and his disciples, anxious to combine as many elements as possible in their new world-religion, added to the confusion by their readiness to identify their master with the most incongruous personalities. Simon is a true magician in this at least, that he still eludes our grasp. The legend of Simon and Helena continued to be read in the middle ages; and several traits of Simon may be recognised in 'Doctor Faustus.'

See Baur's *Paul*, and his *History of the Church in the First Three Centuries* (both translated), and earlier works there cited; Hilgenfeld's *Clem. Recognitionen u. Homilien* (1848); Zeller's *Apostelgeschichte* (1854); Lipsius in Schenkel's *Bibel-Lexicon* (1875) and his *Apokr. Apostelgeschichten* (1877); Harnack's *Gnosticismus* (1873), his article 'Simon' in *Ency. Brit.*, and his *Dogmengeschichte*, vol. i. (1886).

Simonoseki. See SHIMONOSEKI.

Simony (derived from Simon Magus), in English law, means, according to Blackstone, the offence of obtaining orders or a license to preach by money or corrupt practice. But the term is now commonly used to denote the offence of presenting or procuring presentation to a benefice for money. In the canon law this was considered a heinous crime and a kind of heresy. As the canonical punishment, however, was not deemed sufficient, a statute was passed in the time of Elizabeth defining its punishment. A simoniacal presentation was declared to be utterly void, and the person giving or taking the gift or reward forfeited double the value of one year's profit; and the person accepting the benefice was disabled from ever holding the same benefice. Presentation bonds, however, taken by a patron from a presentee to resign the benefice at a future period in favour of some one to be named by the patron, are not illegal, provided the nominee is either by blood or marriage an uncle, son, grandson, brother, nephew, or grandnephew of the patron, and provided the bond is registered for public inspection in the diocese. The result of the statutes is that it is not simony for a layman or spiritual person, not purchasing for himself, to purchase, while the charge is filled, either an advowson or next presentation, however immediate may be the prospect of a vacancy, unless that vacancy is to be occasioned by some agreement or arrangement between the parties. Nor is it simony for a spiritual person to purchase for himself an advowson, although under similar circumstances. It is, however, simony for any person to purchase the next presentation while the church is vacant; and it is simony for a spiritual person to purchase for himself the next presentation, although the charge be occupied. See ADVOWSON, and Cripps's *Laws of the Church and Clergy*.

Simoom, or SIMOON (Arab. *samúm* or *samún*; from *samm*, 'poisoning'), is a hot, suffocating wind common in the deserts of Africa and Arabia, as well as in Sind and Beluchistan. It is essentially of the same nature as a cyclone: there is a central tract of calm surrounded by violent eddies of intensely heated air, and the entire system keeps moving slowly forward, generally from south to north or from east to west. Its presence is heralded by whirling currents of air, and indicated by the purple colour of the atmosphere. It often carries with it huge rotating columns of sand, or stifling gusts and showers of fine sand. It is highly deleterious to men and animals, causing the sensation of suffocation, together with great pain in the limbs. Spring and summer are the usual times of its occurrence; but it seldom lasts many minutes, not more than twenty at the outside. See DESERT, STORMS, WHIRLWIND.

Simplon (Ital. *Sempione*), a mountain-pass (6594 feet high) of Switzerland, situated in the east of the canton of Valais. The Simplon Road, one of the greatest engineering achievements of modern times, leads over a shoulder of the mountain from Brieg in Valais to Domo d'Ossola (41 miles) in the valley of the Toce, which flows into Lago Maggiore. The road was commenced in 1800 under the direction of Napoleon, and was completed in 1806, at a cost of £720,000. It is from 25 to 30 feet broad, and has nowhere a slope greater than 1 in 13. It is carried across more than six hundred bridges, over numerous galleries cut out of the natural rock or built of solid masonry, and through great tunnels. Close to the highest point is the New Hospice (opened in 1825), one of the twenty edifices on this route for the shelter of travellers. For some time a plan has been under discussion for constructing a railway tunnel through the Simplon, and was practically resolved on in 1891. The estimated cost was 3¼ million pounds sterling, the length 12¼ miles, and the time occupied in the boring was to be 8½ years.

Simpson, SIR JAMES YOUNG, physician, was born at Bathgate, Linlithgowshire, 7th June 1811, a baker's son, the youngest of a family of eight. He early showed a peculiar talent for medical observation and research; and in the prosecution of his professional studies at the university of Edinburgh, which he entered at the age of fourteen, he so attracted the notice of his teachers as to inspire all of them with an active interest in his future career. He took his M.D. in 1832, his thesis on *Death from Inflammation* winning the highest admiration; and in 1835 was elected president of the Royal Medical Society. Professor Thomson chose him as his assistant (1837-38), and employed him in the preparation of his course of lectures on General Pathology. During the illness of the professor he supplied his place in the lecture-room with unusual skill and address. He now began professional practice on his own account, and in 1840 succeeded Professor Hamilton in the chair of Midwifery. This position he held with yearly enhanced distinction, and by the rigidly scientific, while popularly attractive, character of his prelections contributed greatly to the renown of the Edinburgh school, both at home and abroad. He was indefatigable, amid the distracting cares of an extensive practice, in promoting the scientific perfection of his art; and his *Obstetric Memoirs* (2 vols. 1856), edited by Drs Priestley and Storrer, contains the fruits of much patient and ingenious research. In 1847 he was appointed one of Her Majesty's Physicians for Scotland. The discovery by which he will be more particularly remembered is that of the anæsthetic virtues of chloroform. The so-called sulphuric ether had been employed in America by Morton to produce Anæsthesia (q.v.) during labour; but to Simpson belongs the credit of first, in March 1847, introducing chloroform to the scientific world. In 1859 he recommended the stopping of hæmorrhage by Acupressure (q.v.). In his own peculiar field of obstetrics his improvements on the old methods of practice were numerous and valuable; his antiquarian researches are embodied in his posthumous *Archæological Essays* (1872). He was created a baronet in 1866, and died 6th May 1870. A bronze statue was erected in Edinburgh in 1877.

Besides the *Obstetric Memoirs* already mentioned his medical and archæological works include a volume on *Acupressure* (1864), one on *Homœopathy, Selected Obstetrical Works, Anæsthesia, Clinical Lectures on the Diseases of Women*, and many papers and notices read before the Royal and Antiquarian Societies of Edinburgh upon Leprosy, Cholera, Syphilis in Scotland, &c. See the *Memoir* by Duns (1873).

Simpson, THOMAS, one of the most eminent of the numerous non-academic mathematicians of England, was born on the 20th August 1710, at Market Bosworth in Leicestershire. His father was a stuff-weaver, and, intending his son to follow the same occupation, gave him little or no education. The son, however, had a taste for study, and embraced every opportunity for gratifying it. In consequence he quarrelled with his father and went to Nuneaton. Here he worked at his trade, and eked out his earnings by teaching an evening school and by casting nativities. The last occupation threatening to get him into difficulties, he removed to Derby, where he remained from 1733 to 1735 or 1736. Thence he went to London, and began teaching mathematics. In 1737 he published a *Treatise of Fluxions;* in 1740 a *Treatise on the Nature and Laws of Chance*, and a volume of *Essays on Several Subjects in Speculative and Mixed Mathematics;* in 1742 the *Doctrine of Annuities and Reversions;* in 1743 *Mathematical Dissertations on Physical and Analytical Subjects;* in 1745 a *Treatise of Algebra;* in 1747 *Elements of Geometry;* in 1748 *Trigonometry Plane and Spherical;* in 1750 the *Doctrine and Application of Fluxions;* in 1752 *Select Exercises for Young Proficients in the Mathematics;* and in 1757 *Miscellaneous Facts*. He was a frequent contributor to the *Ladies' Diary*, of which he was the editor from 1754 to 1760. In 1743 he was appointed professor of Mathematics in the Royal Academy at Woolwich, and in 1745 he was admitted a Fellow of the Royal Society. He died on the 14th May 1761. A biographical notice by Dr Charles Hutton, giving some curious details of Simpson's life, is prefixed to Davis' edition (1805) of the *Doctrine and Application of Fluxions*.

Simrock, KARL JOSEPH, a German poet and scholar, whose name is indissolubly associated with the revival of interest in old German literature, was born at Bonn, 28th August 1802. He studied at the university of his native city and at Berlin, and in 1826 entered the Prussian state service. His first work was a translation into modern German of the *Nibelungenlied* (1827; 50th ed. 1890). Soon after the publication of his translation of Hartmann von der Aue's *Armer Heinrich* (1830) he was compelled to leave the Prussian service on account of a revolutionary poem which he had written. Afterwards he devoted himself exclusively to literature, and more particularly to the early literature of his own country, which he has modernised in excellent style—e.g. the poems of Walter von der Vogelweide (1833), Wolfram von Eschenbach's *Parzival* (1842), *Reineke Fuchs* (1845), *Die Edda* (1851), Gottfried von Strasburg's *Tristan und Isolde* (1855), the *Heliand* (1856), *Beowulf* (1859), *Der Wartburgkrieg* (1858), Brant's *Narrenschiff* (1872), &c. Besides these editorial labours he translated Shakespeare's poems and some of his plays, and published *Quellen des Shakspeare in Novellen, Märchen, und Sagen* (3 vols. 1831), in conjunction with Echtermeyer and Henschel; *Novellenschatz der Italiener* (1832); *Rheinsagen aus dem Munde des Volkes und Deutscher Dichter* (1836); a collection of German *Volksbücher* (13 vols. 1844–67), comprising national proverbs, songs, and riddles, besides a vast quantity of stories; *Das Heldenbuch*, partly translations and partly original poems (6 vols. 1843–49) illustrative of the heroic traditions of the Teutonic race; his own *Gedichte* (1844); and a considerable number of handbooks. In 1850 he was appointed professor of Old German Language and Literature at Bonn, a post which he held till his death, on 18th July 1876. See a monograph on him by Hocker (Leip. 1877).

Sims, GEORGE ROBERT, born in London, 2d September 1847, joined the staff of *Fun* in 1874, in 1877 commenced his 'Dagonet' contributions to the *Referee*, and also contributed series of papers to the *Weekly Dispatch*. Among his plays are *Crutch and Toothpick* (1879), *Mother-in-law* (1881), *The Lights o' London* (1881), *The Romany Rye* (1882), and, among others written in collaboration, *In the Ranks* (1883), *Harbour Lights* (1885), *The Golden Ladder* (1887), and *The Grey Mare* (1892). His novels include *Rogues and Vagabonds*, *Memoirs of Mary Jane*, *Mary Jane Married*, *Dramas of Life*, *Memoirs of a Mother-in-law*, &c.; and his letters to the *Daily News* on the housing of the London poor also deserve mention.

Simson, ROBERT, was born in Ayrshire on the 14th October 1687. He was educated at the university of Glasgow with a view to entrance into the church, but, finding theology uncongenial, he devoted himself to mathematics, and specially to geometry. In 1711 he was appointed professor of Mathematics in Glasgow, and he occupied this chair for the long period of half a century. One of the first subjects to which he turned his attention was the restoration of Euclid's lost treatise on *Porisms*. This had been previously attempted, but without success, owing to Pappus' meagre and obscure description of what a porism was. It is Simson's greatest achievement that he elucidated the nature of the ancient porisms, though his restoration of them is not complete. A specimen of his discovery was printed in the *Philosophical Transactions* of the Royal Society of London in 1723, but his treatise on the subject did not appear till after his death. His *Sectiones Conicæ*, in five books, was published in 1735; the first three books were afterwards translated into English, and have been repeatedly printed. His restoration of Apollonius' *Plani Loci* had been finished about 1738, but was not published till 1749. The work by which he is best known is his *Elements of Euclid*, which appeared both in Latin and English in 1756. It contained the first six books, the eleventh and twelfth, and was the basis of nearly all the editions published for more than 100 years afterwards. In 1761 he resigned his professorship, and occupied himself till his death, which took place on the 1st October 1768, in the arrangement and correction of his mathematical papers. His only publication after his retirement was a second edition of the *Elements* (1762), to which he annexed the book of *Data*. In 1776 a large volume, *Roberti Simson Opera quædam Reliqua*, was printed at the expense of Earl Stanhope, one of Simson's intimate friends, and liberally distributed. It contains a restoration of Apollonius' two books *De Sectione Determinata*, with the addition of other two *De Porismatibus*, and two tracts on logarithms and the limits of quantities and ratios. See Memoir by the Rev. W. Trail (1812).

Sin is not simply moral evil as recognised by the awakened human conscience, but guilt before God or the gods. Some doctrine of sin, and of the mode of averting the anger of the deity, of reconciling him, and of escaping from the guilt, is accordingly part of most religions, ancient and modern. Zoroastrianism is a conflict of sin and holiness. The central doctrine of Buddhism turns on the demerit of human actions and human life, which must be purged by transmigration. But in no sacred books is the sense of sin so keen and developed as in the Bible—in the writings of the prophets of the God of holiness, in the psalms, in the gospels, and in Paul's epistles. From Paul's various utterances on the great subject of sin the latest Christian doctrine professes to be but a development.

Throughout the Scriptures sin appears as that element in man which puts him at enmity with God, and for his salvation from its guilt and power required the work of a Redeemer (see CHRISTIANITY). Sin is not defined in Scripture, and it was not till the controversies between Pelagius and Augustine, at the end of the 4th century, that the doctrine received full development. The early Greek fathers regarded sin as opposition to the will of God, and as such involving death as its just penalty. But they did not affirm that the guilt of Adam's sin or the corruption of his nature descended to all mankind. Tertullian, in virtue of his doctrine of Traducianism, was bound to hold that sinfulness had been propagated from Adam to his descendants. But it was reserved for Augustine to maintain, against Pelagius, that Adam's sin completely corrupted his whole nature; that the corruption of his guilt and its penalty death pass to all his children; that man is born not merely corrupt, but in a state of sin, guilt, and liability to punishment; in virtue of Adam's *peccatum originale*, the offspring of Adam is a *massa perditionis*, incapable of knowing, or loving, or serving God, and naturally disposed, without grace, to pursue evil only, the will being enslaved to evil. Pelagius (q.v.) maintained contrary doctrines, and semi-pelagianism insists that in spite of the weakening of his powers through hereditary sinfulness man is yet not wholly inclined to evil. The Greek Church continued to deny hereditary guilt, and to affirm man's will as free as Adam's before the fall. Duns Scotus and his followers admitted that man had lost by Adam's fall *justitia originalis*, but laid stress on the freedom of the will. Thomas Aquinas taught that hereditary sin is truly sin, and the unbaptised infant is damned. At the Reformation both Luther and Calvin asserted what they regarded as Augustinian and Pauline views. Zwingli looked on hereditary sin as an inherited evil or disease: Arminians and Socinians practically denied hereditary sin altogether. In modern German speculation the Hegelians taught that sin was a necessary condition of the development of mankind; and Schleiermacher that the sinful state of man was a disturbance of his nature, not a necessary condition of it. The problems connected with sin are closely akin to those connected with the origin of evil and the freedom of the will.

The doctrine of the Thirty-nine Articles (Art. ix.) is as follows: 'Original sin standeth not in the following of Adam (as the Pelagians do vainly talk); but it is the fault and corruption of the nature of every man, that naturally is engendered of the offspring of Adam, whereby man is very far gone from original righteousness, and is of his own nature inclined to evil, so that the flesh lusteth always contrary to the spirit; and therefore in every person born into the world it deserveth God's wrath and damnation.'

The Westminster Confession teaches (chap. vi.): 'By this sin' (i.e. the eating of the forbidden fruit) 'they' (i.e. our first parents) 'fell from their original righteousness and communion with God, and so became dead in sin, and wholly defiled in all the faculties and parts of soul and body. They being the root of all mankind, the guilt of this sin was imputed, and the same death in sin and corrupted nature conveyed to all their posterity, descending from them by ordinary generation. From this original corruption, whereby we are utterly indisposed, disabled, and made opposite to all good, and wholly inclined to all evil, do proceed all actual transgressions.'

Sins have been divided into categories, as sins of omission and of commission, deliberate voluntary sins and involuntary sins, sins of infirmity, &c. The 'sin unto death' (1 John, v. 17), generally identified with the unforgivable 'blasphemy against the Holy Spirit' (Matt. xii. 31), or 'sin against the Holy Ghost,' is understood not to mean profane speaking against the person of the Holy Spirit, or resisting His operations, but a state of obstinate, malignant deadness of heart, and unrepentant and unhesitating hatred to all good. The distinction accepted by Catholic theology between mortal and venial sins is explained at CONFESSION.

See ADAM, ATONEMENT, AUGUSTINE, CHRISTIANITY, DEVIL, ETHICS, EVIL, FALL, HELL, PAUL, PELAGIUS, SACRIFICE, TRANSMIGRATION, WILL; also Julius Müller's *Christliche Lehre von der Sünde* (1839-44; Eng. trans. from 3d ed. 1852, 5th ed. 1877); Principal Tulloch's *Christian Doctrine of Sin* (1876), and A. Brown's *Doctrine of Sin* (1881); Cardinal Manning's *Sin and its Consequences* (1874); Ernest Naville's *Problem of Evil* (Eng. trans. 1872); Rev. O. Shipley's *Theory about Sin* (1874), and *Principles of the Faith in Relation to Sin* (1878).

Sinai, the sacred mountain on which Moses received from Jehovah the tables of the Ten Commandments, is an individual peak in a vast rocky mass that almost fills the peninsula of Sinai. This peninsula is situated on the north-west of Arabia, and is embraced between the Gulf of Suez and the Gulf of Akaba, northern arms of the Red Sea, and is shut in on the north by the desert. In this mountain-mass there are three separate mountains clearly distinguishable—Mount Serbal (6750 feet); Mount Catherine (8540 feet), lying south-east of Serbal; and Umm Shomer (some 8000 feet). Authorities, ancient theologians and historians and modern travellers and commentators, are greatly divided on the identification of the Sinai of Moses, some (Eusebius, Jerome, Lepsius, Ebers, &c.) upholding the claims of Serbal, others (Farrar, Tischendorf, Strauss, Stanley, Palmer, Sir Charles Warren, Hull, &c.) contending for Mount Catherine. Tradition has pointed to the latter ever since the time of Justinian, but the vexed question is yet far from being settled. The mountain known as Jebel Katherin has two well-marked peaks, a northern one called Horeb and a southern called Jebel Musa (Mountain of Moses). It is this last summit which tradition has selected as the sacred mountain of the Hebrew law-giving. At its foot, in a ravine, stands the fortress-like monastery of St Catherine (founded probably about 527 by the Emperor Justinian), and a short distance above it the chapel of St Elias (Elijah); whilst on its summit is the little pilgrim church. The entire peninsula, especially the bold jagged mountains, has a stern, treeless appearance, though trees (the manna-tamarisk, acacias, date-palms, gum-shrubs, &c.) grow in the ravines, beside the watercourses. Four or five thousand Bedouins range over the peninsula, and feed their sheep and goats in the pasturages of the higher valleys. There are several caves amongst the mountains; these, in the early days of Christianity, were the favourite abodes of numbers of hermits or anchorites. And there are a great many Nabatæan (q.v.) inscriptions engraven on the rocks of Sinai, which date from the early centuries of the Christian era.

See amongst other books, Hull, *Mount Seir, Sinai, and West Palestine* (Lond. 1885); Palmer, *Desert of the Exodus* (Camb. 1871); Stanley, *Sinai and Palestine* (1856); *Ordnance Survey of the Peninsula of Sinai* (3 vols. Southampton, 1869); and J. Euting, *Sinaitische Inschriften* (1892); also CODEX, TISCHENDORF.

Sinaloa, one of the Pacific states of Mexico with an area of 36,180 sq. m. and a pop. of 223,684. It contains over 100 mining districts, chiefly producing silver. The capital is Culiacan (q.v.), 100 miles north-west of which is the small town of Sinaloa, with a pop. of 2000.

Sinclair. See Roslin.

Sinclair, Sir John, born at Thurso Castle, 10th May 1754, from Logan's tutorship passed to the High School of Edinburgh, and thence to the universities of that city, Glasgow, and Oxford. He was admitted a member of both the Scottish and English bars (1775–82), but, having in 1770 succeeded to the family estate, he devoted himself to his duties as a northern landlord, and to the more engrossing pursuits of public life. In 1780 he was returned to parliament for Caithness, in 1784 for Lostwithiel, and in 1796 for Petersfield, his parliamentary career extending till 1811. In 1784 he published a *History of the Revenue of the British Empire;* and in 1786 he was created a baronet. He travelled over Europe, gathering information on economical and commercial questions, and on his return set about establishing a society in Scotland for improving the breeds of sheep and the quality of wool. His exertions also led to the formation of the Board of Agriculture in 1793, of which he was president for thirteen years. This institution was the precursor of numerous agricultural associations, by which the country was greatly benefited. Sir John's most important undertaking was originating and carrying through the *Statistical Account of Scotland* (21 vols. 1791–99), comprising a description of every parish in Scotland. The parochial clergy were the chief contributors, but the indefatigable baronet also employed statistical missionaries, and was for seven years actively engaged in prosecuting the work. Sir John wrote on all manner of topics, including even a tragedy and treatises on health and longevity; and his publications during fifty years of ceaseless exertion are said to amount in number to 39 volumes and 367 pamphlets. Not one of the whole seems destined to live; their value perished in the using; but the long and active life of their author was highly beneficial to his country. He died at Edinburgh, 21st December 1835, aged eighty-one. See his Correspondence (2 vols. 1831) and Life (2 vols. 1837).

Sir John Sinclair left a numerous family, of whom the third son, John (1797–1875), was archdeacon of Middlesex from 1842, and author of *Sketches of Old Times* (1875), &c.; whilst the fourth daughter, Catherine (1800–64), wrote a number of tales and descriptive works—*Modern Accomplishments, Modern Society, Scotland and the Scotch, Shetland and the Shetlanders,* &c.—all evincing literary taste and fine moral feeling.

Sind, or Sindh (also spelt *Sinde* and *Scinde*), a province in the north-west of British India, belongs to the presidency of Bombay, and is bounded on the N. by Beluchistan and the Punjab, E. by Rajputana, W. by Beluchistan, and S. by the Indian Ocean and the Runn of Cutch. It contains an area of 56,632 sq. m., with a pop. (1891) of 2,900,000. The seacoast (150 miles) is very low and flat, with the exception of the small portion beyond Karachi (Kurrachee), and is studded with low mud-banks formed by the Indus or with sandhills, the accumulated drift from the beach. The province is traversed from north to south by the Indus (whence the name; see India, Vol. VI. p. 98), and includes the whole of its delta. Along each bank of the river is an alluvial tract of great fertility, from 2 to 12 miles wide, and mostly irrigated by artificial canals and water-courses, which, overflowing during the inundations, cover the soil with a silt so rich as to yield two, and sometimes three, crops in a year. The soil, nevertheless, contains in the north so much saltpetre, and in the south so much salt, that after the year's crops have been obtained these substances are extracted for home consumption and export. Between the Indus and its most easterly branch, the Nara, is an alluvial 'doab,' which, from want of irrigation, has become almost a desert. East of this is the Thur, a desert of shifting sand. West of the Indus the country is occupied by the desert of Shikarpur on the north, a desert not of sand, but of alluvial clay, the same as that of the delta, which only requires irrigation to render it fertile; and in the south it is traversed by the Hala Mountains. The climate is remarkably sultry and dry, the province being beyond the action of the south-west monsoon; during the long summer the thermometer averages 95° F., and ranges up to 120°; in winter it falls below freezing-point and rises to 80°. There are generally two harvests per annum; the first, or *rabi* ('spring') harvest, consists of wheat, barley, indigo, oil-seeds, gram, hemp, and tobacco; the second, or *kharif* ('autumn') harvest, of rice, millet, oil-seeds, pulses, and cotton. The population consists of the native Sindis, with a large sprinkling of Beluchis and Afghans; the greater portion of them are Mohammedans of the Sunnite faith. The population are almost wholly engaged in agriculture. The trade of the province is concentrated at Kurrachee (q.v.), the capital. Raw cotton, wool, and various grains are the principal exports. Besides Kurrachee (pop. in 1891, 104,250), there are the large towns of Hyderabad (57,790), Shikarpur, Larkhana, and Sukkur.

About 712 A.D. Sind was conquered by Mohammed Kasim, the general of the calif, and since that time has been almost entirely ruled by Mohammedan princes. About 871 the califs lost their hold upon this province, which became divided between the two native kingdoms of Multan and Mansura. In 1026 Sind was conquered by an officer of Mahmud of Ghazni, but the conquest was not at all a permanent one. A new native dynasty was founded in 1051, and was followed by others in 1351 and 1521. In 1592 the country was conquered by Akbar, the Mogul emperor of Delhi; and in 1739 it was incorporated in the dominions of Nadir Shah of Persia. Under Persian suzerainty Sind was governed by various native dynasties. The rulers of Sind always regarded the British with suspicion, and not without reason, for on the outbreak of the Afghan war in 1838 the British government forced the chiefs of Hyderabad and Khairpur to agree to a treaty which virtually destroyed their independence. And when their Beluchi subjects, resenting this arrangement, took up arms, Sir Charles Napier marched against them, totally routed them at Meeanee (17th February 1843), and at Dabo, near Hyderabad (March 24th), and annexed their territories. The British administrators have directed their chief efforts to the development of the commerce of the country, principally by the construction of the Indus Valley Railway and the harbour-works at Kurrachee (q.v.).

See five volumes by Sir R. Burton (1851–77), and A. W. Hughe's *Gazetteer of the Province of Sind* (1876).

Sindia, the title of the Mahratta princes or rulers of Gwalior in India. The founder of the family was Ranoji Sindia, who from a menial station in the household of the Peshwa rose to a high rank in the bodyguard, and after 1743 received in hereditary fief one-half of the extensive province of Malwa. His son, Mádhava Rao (Madhoji) Sindia (1750–94), joined the Mahratta confederation, and was present at the battle of Panipat (1761), where he was so desperately injured as to be left for dead; but he recovered. In 1770, along with the Peshwa and Holkar, he aided the emperor of Delhi to expel the Sikhs from his territories, the administration of which was handed over to Sindia, thus making him the most powerful of the Mahratta chiefs. He first came into collision with the British in 1779; but in the war which followed fortune distributed her favours with impartiality, and by the treaty of Salbye (1783) Sindia was recognised as a sovereign prince and confirmed in all his possessions. In 1784 he captured the stronghold of Gwalior, and in the following year marched on Delhi, and subsequently seized Agra, Alighur, and nearly the whole of the Doab (q.v.). The manifold advantages of European discipline had struck him forcibly during the war with the British, and, with the aid of an able French officer, he raised and drilled an army of troops, with whom he reduced Jodhpur, Udaipur, and Jeypore, three Rajput states, and effectually humbled the pride of Holkar. See H. G. Keene's *Mádhava Rao Sindhia* ('Rulers of India' series, 1892).—DAULAT RAO SINDIA (1794–1827) continued his granduncle's policy, and during the troubles which convulsed Holkar's dominions at the commencement of the 19th century ravaged Indore and Poona, but was routed in 1802 by Holkar. Having joined the rajah of Berar in a raid on the Nizam (1803), he brought down upon himself the vengeance of the East India Company. The confederated Mahrattas were routed at Assaye and Argaum by Sir Arthur Wellesley, and were scattered irretrievably at Laswari by Lord Lake. Thereupon Sindia hastened to sign a treaty by which all his possessions in the Doab and along the right bank of the Jumna were ceded to the British. Gwalior was, however, restored in 1805, and from that time became the capital of Sindia's dominions.—During the reign of MUGAT (JANAKJI) RAO (1827–43), a minor, the Gwalior dominions were in such a state of anarchy that the British felt called upon to interfere; a war ensued, and the Mahrattas were routed at Maharajpûr (December 29, 1843) by Lord Gough, and at Panniar by Major-general Grey on the same day. Gwalior fell into the hands of the British, 4th January 1844, and Sindia submitted to the conditions demanded of him, besides maintaining a contingent force of sepoys at Gwalior. During the Mutiny BAJI RAO (1843–86), successor of Mugat, took the field against the Gwalior contingent, which had joined the rebels; but most of his troops deserted him during the battle (June 1), and he narrowly escaped by fleeing to Agra. He was subsequently reinstated by Sir Hugh Rose, and received from the British government substantial marks of its goodwill and approbation. He was succeeded by his adopted son in 1886, when the British cantonment was removed from Gwalior.

Sindibad. See SEVEN WISE MASTERS.

Sine. See TRIGONOMETRY.

Sin-eaters, a class of men formerly employed in Wales and on the Welsh border, in connection with funeral rites, to eat a piece of bread and drink a cup of ale placed on the bier, and so symbolically take upon themselves the sins of the deceased. As soon as this was done the sin-eater 'pronounced the ease and rest of the soul departed, for which he would pawn his own soul,' and so took his way, having freed the dead sinner from the necessity of walking an unquiet ghost. The name may be due to a mistaken interpretation of Hosea, iv. 8—'They eat up the sin of my people;' but the real origin of this strange custom must undoubtedly be found in the Levitical *scape-goat* (Levit. xvi. 21–22). Aubrey is the chief authority for this usage, and describes it as once common in Shropshire, Herefordshire, and North Wales. It seems also to have been practised in Galloway. See the paper by E. Sidney Hartland in *Folklore* in 1892.

Sinecure (Lat. *sine cura*, 'without care'), in common language, an office which has revenue without employment. In the canon law a sinecure is an ecclesiastical benefice, such as a chaplainry, canonry, or chantry, to which no cure of souls is attached, and where residence is not required. The strictest kind of sinecure is where the benefice is a donative, and is conferred by the patron expressly without cure of souls, the cure either not existing, or being committed to a vicar. Sinecure rectories were abolished in 1840. Sinecure offices were formerly very numerous in the English public service. They were used to enrich ministers of state and their families; Sir R. Walpole, for example, presented his son Horace to three or four sinecure places which brought him in a large income. The number of such places has been greatly diminished by modern reforms; the stewardship of the Chiltern Hundreds (q.v.) and some other offices of merely nominal profit are retained, because by accepting one of them a member of the House of Commons is enabled to vacate his seat.

Sinew. See TENDON.

Singanfoo, the principal city of the Chinese province of Shen-hsi, on a tributary of the Hoang-ho. Pop. stated at 1,000,000.

Singapore, a British dependency in Asia, the most important of the Straits Settlements, consists of the island of Singapore (27 miles long, 14 broad; area, 206 sq. m.), separated from the southern extremity of the Malay Peninsula by a strait only half a mile wide at its narrowest, and of a great number of very small islands along its shores. The surface is undulating, the highest point reaching 520 feet only. The climate is hot and moist, but the soil is not particularly fertile; nevertheless the island is perpetually clothed with verdure, and yields good crops of coffee, pine-apples, cocoa-nuts, aloes, and every kind of fruit, especially East Indian fruit (e.g. mangosteen and durian). Gambier, pepper, and nutmegs used formerly to be the staple crops; but all three are cultivated to a much smaller extent than formerly. This island was purchased in 1824 from the sultan of Johore for £12,500 and a liferent of £5000. Pop. of island (1881) 172,993; (1891) 182,650.

The *capital* of the dependency, Singapore, is the only town on the island. It occupies a pleasant site on the south-east coast, on the Strait of Singapore, the principal waterway for vessels trading between eastern Asia and India and Europe. This city was founded by Sir Stamford Raffles in 1819 as an emporium for British trade in the East Indies, and it has since that time advanced and grown in prosperity till it has become the most important trading-place in the south-east of Asia, its only competitor being Batavia in Java, from which it is 600 miles distant. Singapore is a picturesque, well-built town, with fine public buildings and all kinds of appliances in the nature of public works. It possesses a governor's residence, St Andrew's Protestant cathedral (1861–70), a Roman Catholic cathedral, Mohammedan mosques, Hindu temples, Chinese joss-houses, Raffles museum (1823), the supreme law-courts, post-office (1883), hospitals, gaol, barracks, and fine botanical and zoological gardens. It is defended by numerous batteries and forts, and is a naval coaling station and depôt. The docks, stores, and dwelling-houses extend for 6 miles or more along the sea-front. The harbour is spacious and safe and remarkably easy of access, and its dock accommodation embraces two graving-docks, an admiralty dock, and several docks of the ordinary kind. The total annual trade of Singapore has increased at a remarkable rate since the city was founded: in 1823 (counting in the trade of George-town, the capital of Penang) it reached the value of £2,000,000; in 1851, £5,740,000; 1870, £23,051,000; 1889, £41,548,000. The imports exceed the exports to the extent of one-fourth: the total exports in

1889 were valued at £18,476,000, the imports at £23,072,000. The imports embrace nearly every kind of European manufacture, whilst the exports consist of the productions of the East Indies, China, Japan, and the islands of the Western Pacific. The tonnage of the vessels entering the port has been known to increase at the rate of 74 per cent. annually: in 1889 the harbour was entered by 7715 vessels of nearly 6,114,000 tons. The vessels of the P. and O. Company, the Messageries Maritimes, and other large companies trading to China, Australia, and the East put in regularly at Singapore. The population has grown at the same rapid rate as the commerce: in 1824 the town had 10,603 inhabitants; (1850) 50,000; (1871) 97,111; (1881) 139,208; (1891) 160,000. This number included about 90,000 Chinese, 25,000 Malays, 12,000 natives of India, and 1300 Europeans. There is a vast disproportion between the numbers of the male (105,423) and the female (33,785) inhabitants. The death-rate is high, yet the climate, in spite of Singapore being situated little more than 1° N. of the equator, is uniform and agreeable, the nights being particularly cool and refreshing. The thermometer ranges between 67° and 94° F. and has a mean of about 82°. The rainfall varies from 65·6 to 92·2 inches in the year. There was a former town on the site of the present city, which was founded by Malay converts to Hinduism from Java or Sumatra, apparently in the 12th century; but it had wholly disappeared when Sir S. Raffles laid the foundations of the existing Singapore (i.e. 'Lion City'). It was made the capital of the Straits Settlements (q.v.) in 1830, superseding Penang.

Singbhum, one of the four districts of the division of Chota Nagpore (q.v.), with no large towns.

Singeing Cake. See HOST.

Singhara Nut. See TRAPA.

Singing. See MUSIC, OPERA, ORATORIO, SOLFEGGIO, VOICE, SONGS.—For Singing-flames, see FLAME.

Single-stick. See FENCING, Vol. IV. p. 578; and *Broadsword and Singlestick*, by Allanson-Winn and Phillipps-Wolley (1890).

Sing Sing, a post-village of New York, pleasantly situated on the left bank of the Hudson (here 3 miles wide, and called Tappan Bay), 31 miles by rail N. of New York City. It contains many villas and a number of boarding-schools, and has some busy manufactories; but it is most widely known as the site of the large state-prison which rises from the bank of the river, and has been built since 1825. The Croton Aqueduct rests here on an arch of masonry with a span of 88 feet. Pop (1890) 9352.

Sinigaglia, or SENIGALLIA (anc. *Sena-Gallia*), a seaport on the Adriatic coast of Italy, 16 miles by rail NW. of Ancona, was down to 1869 celebrated for its annual fair, 20th July to 8th August. It was founded by the Senonian Gauls, and colonised by the Romans 289 B.C. There are here a cathedral (1787) and a palace of the dukes of Urbino. Pop. 9602. Pius IX. was born here.

Sinister. See HERALDRY, Vol. V. p. 661, and BATON-SINISTER.

Sinking Fund, a fund formed by setting aside income every year to accumulate at interest for the purpose of paying off debt. A sinking fund for payment of the national debt of Britain was begun in 1716 by Sir Robert Walpole. Certain taxes which had been laid on for limited periods were then rendered perpetual, for the purpose of paying the interest of the funded debt. They produced more than enough for this purpose, and the surplus was laid aside, that it might accumulate into a fund for extinguishing the debt. It appeared to operate well, since, in 1728, after it had existed for twelve years, debt was wiped off to the extent of £6,648,000. It was not observed that, *during the wiping off*, new debt had been created to about the same extent, so that the nation was just in the position in which it would have been had it neither borrowed nor repaid. It was in 1784–86, however, that the system was established on a great scale by the younger Pitt, who, notwithstanding his great practical abilities, was entirely misled by the theories of Dr Price in his work on Annuities. The system continued to be conducted on an enormous scale, until another student of economy and figures conclusively proved it to be useless; this was accomplished in 1813 by Dr Hamilton, in his Inquiry on the National Debt. The fallacy which Dr Hamilton showed to pervade the sinking fund of Mr Pitt may be best explained by a simple example. Suppose that one requires to borrow £100, and lays by £5 a year as a fund to pay it up with. Accumulating at compound interest, this fund will pay back the loan in about fifteen years. The borrower will, however, gain no more by the process than if he paid the £5 a year to his creditor, for his debt would be diminishing to precisely the same extent as the fund to pay it off would be increasing. Suppose that, while requiring only £100, the borrower raises £200, and lends out one of them, accumulating the interest until the whole amounts to £200; the borrower will no doubt be receiving interest on £100, but he will be at the same time paying interest on £200; and he would repay his debt at the same cost and with more simplicity if, instead of borrowing the second hundred at 5 per cent., he paid over £5 a year to his creditor. In these instances nothing is lost by the sinking fund. But suppose that in the last case the creditor had agreed to lend the £100 at 5 per cent., but, in consideration of the greater risk, would not lend the £200 at less than 6 per cent., while the borrower can only get 5 per cent. for the half which he relends—here the transaction would cause a dead loss of £2 a year over the plan of repaying by instalments. This was exactly the case with the British sinking fund. The more money the Chancellor of the Exchequer wanted the higher were the terms demanded by the lenders, and the addition to each loan on account of the sinking fund increased the rate of interest paid. A new sinking fund on a better plan was started by Sir S. Northcote (Lord Iddesleigh) in 1875, the permanent charge for debt being fixed at 28 millions. As usually happens in such cases, the fixed rule was not observed; Sir S. Northcote's scheme was suspended by Mr Childers and Sir W. Harcourt, and altered by Mr Goschen. See NATIONAL DEBT, Vol. VII. p. 405; and R. L. Nash, *Sinking Fund and Redemption Tables* (1884).

Sinope (Turk. *Sinub*), a town of Asiatic Turkey, stands on a rocky tongue projecting into the Black Sea, 220 miles W. by N. of Trebizond. It has two harbours, one presenting the finest anchorage along the northern coast of Asiatic Turkey. The town is surrounded by ancient Byzantine walls, and has a ruined castle built under Byzantine influence. The bay was the scene of a naval engagement on 30th November 1853, when a Turkish squadron was destroyed by the Russian fleet. The ancient city of Sinope was founded by a colony of Milesian Greeks, and for several years shared with Byzantium the supremacy of the Euxine. It was made by Pharnaces the capital of the kingdom of Pontus in 183 B.C. The great Mithridates, who was born within its walls, raised it to a lofty pitch of splendour. But in 72 B.C. it capitulated to Lucullus, and in 45 B.C.

was made a Roman colony. After belonging successively to the empire of Trebizond (from 1204) and the Seljuks, it was conquered by the Turks in 1461. Sinope was the birthplace of Diogenes the cynic. Pop. 8000.

Sinter, the name given by German mineralogists to those rocks which are precipitated in a crystalline form from mineral waters. Sinter is of various forms, kidney-shaped, knotted, tuberous, botryoidal, tubular, stalactitic, shrub-like, or pronged, and is occasionally distinguished by its chief component, as Calc-sinter, Siliceous sinter, Iron-sinter, &c. Calc-sinter, which is a variety of carbonate of lime, composed of concentric plane parallel layers, appears under various forms; it is deposited with extraordinary rapidity by many springs, a peculiarity frequently made use of to obtain the incrustation of objects with a coating of this substance. Siliceous sinter is mostly found in intermittent hot springs, as in the Geysers (q.v.) of Iceland. Iron-sinter occurs in old mines and in coal-beds, where it is formed from iron pyrites through the agency of the atmosphere. The tubular conglomeration of grains of sand half-melted by lightning (*blitz*) is also known as Blitz-sinter, or Fulgurite (q.v.).

Sinus, in Anatomy, a term for the air cavities contained in the interior of certain bones—as the frontal, ethmoid, sphenoid, temporal, and superior maxillary. The frontal sinuses are two irregular cavities extending upwards and outwards, from their openings on each side of the nasal spine, between the inner and outer tables of the skull, and separated from one another by a thin bony septum. They give rise to the prominences above the root of the nose called the superciliary ridges. They are not fully developed till after puberty, and vary considerably in size, being usually larger in men than in women and young persons. When very much developed they give a receding appearance to the forehead. They are larger in Europeans than in Negroes, and are very imperfectly developed in the Australians, whose peculiar want of vocal resonance is apparently due to this deficiency. They communicate on each side of the upper part of the nostril by a funnel-shaped opening, which transmits a prolongation of mucous membrane to line their interior. These sinuses are much more highly developed in certain mammals and birds than in man. Sir Richard Owen observes that 'they extend backwards over the top of the skull in the ruminant and some other quadrupeds, and penetrate the cores of the horns in oxen, sheep, and a few antelopes. The most remarkable development of air-sinuses in the mammalian class is presented by the elephant; the intellectual physiognomy of this huge quadruped being caused, as in the owl, not by the actual capacity of the brain-case, but by the enormous extent of the pneumatic cellular structure between the outer and inner plates of the skull.' The sphenoidal sinuses are two large irregular cavities, formed, after the period of childhood, in the body of the sphenoid bone. They communicate with the upper part of the nose, from which they receive a layer of mucous membrane. Like the frontal sinuses, they serve to lessen the weight of the skull, and to add to the resonance of the voice. The ethmoid sinuses lie in the lateral masses of the ethmoid bone. They communicate with the cavities of the nose. Their main use is to diminish the weight of the forepart of the skull. That part of the temporal bone which forms the projection behind the ear is termed the *mastoid process*. The interior of this process is hollowed out with air-sinuses which communicate with the tympanum or middle ear, and through it with the nose. The superior maxillary sinus commonly known as the *Antrum of Highmore* (anatomist, 1613-84, who first accurately described it) is the largest of the sinuses, and the only one present in the infantile skull. Its uses are the same as those of the others, and, like them, it communicates with the nasal cavities.

The term sinus is also applied to certain channels for the transmission of venous blood. These are merely dilated veins formed by the separation of the layers of the dura-mater and lodged in grooves on the inner surfaces of the cranial bones. In Surgery the term *sinus* is nearly equivalent to Fistula (q.v.).

Sion, or Sitten, capital of the Swiss canton of Valais, stands in a picturesque situation in the valley of the Rhone, 16 miles NE. of Martigny by the Simplon Railway. It has a mediæval appearance, owing to three ruined castles perched on the crags above the town, and its cathedral, which has been the church of a bishop since the 6th century. Pop. 5447.

Sion College, on the Victoria Embankment, London, was founded in 1623 as a college and almshouse on the site of a priory in London Wall, by the benefaction of Dr White. A library was added soon after, and the college was incorporated by charters of 1630 and 1664. The college consists of the incumbents of the City of London and its suburbs, who appoint a governing body. Changes were made in the constitution in 1884, the almshouse for ten old men and ten old women being abolished, and a sum being devoted to the maintenance of pensioners (now forty in number); and the new building having been erected on the embankment at a cost of £26,000, the college and library (now a large and valuable one, easily accessible to the public) were transferred hither in 1886.—For Sion House, see Isleswortн.

Siout, or Asioot, the chief city of Upper Egypt, stands near the western bank of the Nile, about 200 miles by rail south of Cairo. It has some fine mosques, an imposing government palace, an American mission school, and well-built dwelling-houses. The people, about 32,000 in number, make black and red earthenware, and fans of ostrich-feathers, and carve ivory. There is some trade (annual value £380,000) with Darfur and Senaar. Siout is built on the site of the ancient Lycopolis; but few remains of the Græco-Egyptian city are extant. From the neighbouring heights of the Libyan mountains, which contain numerous rock-sepulchres, the view over the valley of the Nile is perhaps the finest in Egypt. See F. L. Griffith's *Inscriptions of Siout* (1889).

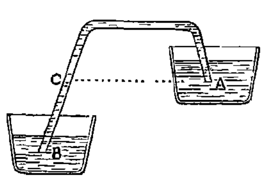
Sioux (pron. *Soo*), the principal tribe of the Dakota (i.e. 'confederate') family of American Indians (q.v.), now settled mostly in South Dakota and Nebraska. Forced by the Chippewas south and west, they made their first cession of lands to the United States government in 1830, and in 1837 ceded all their lands east of the Mississippi, and in 1849-51 those in Minnesota. For all these lands annuities were promised, which were, however, allowed to fall into arrears; and meanwhile the Indians were demoralised by the introduction of whisky. *In 1862 a number of famishing men broke* into a government warehouse, and so began a desperate war which desolated thousands of square miles of territory, cost a thousand whites their lives and the government $40,000,000, and ended in the execution of the leaders. After some years of further disgraceful mismanagement and wrangling between the various government departments, the Santee Sioux were placed on a small reservation near Yankton, where they have developed into industrious and peaceful farmers, and are permitted to hold their lands in severalty (see American Indians, Vol. I. p. 227). Meanwhile the hostile

Sioux had retired to the northern parts of Dakota, where, under Sitting Bull, they gathered the young braves who were exasperated by the government's failure to send supplies to the several agencies. The war which began and ended in 1876 is chiefly memorable for the disaster in which General Custer (q.v.) perished; it was ended in a few months, and Sitting Bull took refuge in Canada, but in 1880 was induced by the Dominion officials, on a promise of pardon, to surrender. The Brulé Sioux and the Ogallalla Sioux were afterwards settled on the Rosebud and Pinewood agencies in South Dakota. In 1890 there was a general rising of the Indians in the North-west, under a 'Messiah;' and in its course Sitting Bull was slain—whether killed in fight or slaughtered was questioned—on 15th December.

Sioux City, capital of Woodbury county, Iowa, on the east bank of the Missouri River (here crossed by a bridge 2000 feet long), 128 miles (by rail) above Omaha and 512 W. by N. of Chicago. It has good public buildings and schools, great stock-yards and packing-houses, railway-shops, planing and spice mills, and manufactures linseed-oil, vinegar, flour, doors and sashes, &c. Pop. (1880) 7366; (1890) 37,806.

Sioux Falls, capital of Minnehaha county, South Dakota, and the largest town in the state, is on the Big Sioux River (which here falls 90 feet), 241 miles by rail SW. of St Paul. A place of 697 inhabitants in 1878, it now has tramways, water-works, gas, the electric light, a public library, a score of churches, and as many manufactories. A leading industry is the quarrying, shaping, and polishing of the granite which underlies the city. Here are the state penitentiary and school for deaf mutes, and four denominational colleges. Pop. (1890) 10,177.

Siphon, a bent tube for drawing off liquid from one vessel to another. When in action the tube must be itself full of the liquid, so that the quantities of liquid in the two vessels form one continuous liquid mass. In accordance with the principles of Hydrodynamics (q.v.), there will be, in these circumstances, a flow of liquid along the tube until either the free surfaces of liquid in the two vessels are brought to the same level, or the one vessel or the siphon becomes emptied of liquid. If it is desired merely to empty one vessel, a second vessel is not necessary. The principle on which the siphon acts will be readily seen by consideration of the figure. The two free surfaces are at the atmospheric pressure, but are at different levels. Take C at the same level as A. Then the pressure at A is obviously greater than the atmospheric pressure, while the pressure at C is less than the atmospheric pressure by the amount of pressure due to the column of liquid between C and the free surface in the lower vessel. Hence there must be a flow of liquid from A to C along the tube—i.e. from vessel to vessel. In the upper part of the siphon the liquid is sustained by the pressure of the atmosphere on the free surface, just as in the Barometer (q.v.). If then the siphon reaches higher above the free surface than the height of the barometer column of liquid used, the continuity of liquid will be broken at the bend, and the siphon will cease to act. Thus a siphon for water cannot be higher than 33 feet above the water surfaces; and a siphon for mercury is similarly limited to 30 inches. To bring it into working condition, a siphon is usually filled by suction applied (either by the mouth or by a pump) at the one end, the other end being immersed in the liquid; or it is first filled with the liquid and then placed in its proper position.



Siphonophora. See HYDROZOA.

Sippara. See BABYLONIA.

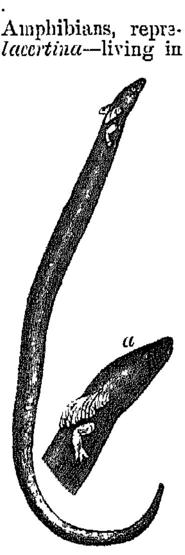
Sipunculus, a genus of worms belonging to the class Gephyrea. The body is cylindrical, unsegmented, without appendages or bristles, with tentacles around the mouth. The food-canal is spirally coiled, and ends anteriorly. The sexes are separate. A common species is *Sipunculus nudus*, which lives in the sand on the shores of the North Sea, the Atlantic, and the Mediterranean. It measures from 6 to 10 inches in length. The animal swallows the sand for the sake of the organic matter therein contained. The members of an allied genus, Phascolosoma, often live within Gasteropod shells, narrowing and extending the mouth of the shell into a tube of cemented sand particles.

Sir (Fr. *sieur* and *sire*, contracted from *seigneur;* from Lat. *senior*, 'elder'), a term originally corresponding to *dominus* in Latin. It was at one time the practice to use the same title in addressing the clergy, a familiar instance being Sir Hugh Evans in the *Merry Wives of Windsor*. To so great an extent did this usage obtain that a 'Sir John' came to be a common sobriquet for a priest. 'Sir' was here a translation of *dominus*, the term used for a bachelor of arts, originally in contradistinction from the *magister*, or master of arts, but eventually extended to the clergy without distinction. Used along with the Christian name and surname, 'sir' is now applied exclusively to knights and baronets. Standing alone it is a common complimentary mode of address used without much consideration of rank or social status. *Sire* is an older form of *sir*, formerly used in addressing royalty.

Sirajganj, a town in Pabna district, Bengal, near the main branch of the Brahmaputra, 150 miles NE. of Calcutta. Pop. 21,037.

Sir-daria. See JAXARTES.

Siren, a genus of tailed Amphibians, represented by one species—*Siren lacertina*—living in swamps in the southern states of North America. The animal is eel-like, of a dark lead colour, one to two feet long, without hind-limbs, with four-toed weak fore-limbs, with three pairs of persistent external gills, with no teeth except on a small patch on the roof of the mouth. The food seems to consist of worms and insects.



Siren lacertina : *a*, head on larger scale.

Siren, an instrument which produces musical sounds by introducing a regularly recurring discontinuity into an otherwise steady blast of air. Seebeck's siren consists of a large circular disc pierced with small holes at equal intervals apart in the same concentric circle. The disc is made to rotate more or less rapidly upon its axis; and while it is so rotating a nozzle, through which a strong blast of air is driven by means of a bellows, is brought so as to bear directly upon any desired circle of holes. When a hole is opposite the nozzle a puff of air escapes; when an unpierced portion of the disc comes before it the air is checked. Thus the blast of air is broken up into a succession of puffs, whose number per second is exactly equal to the number of holes which pass in front of the nozzle in one second. Knowing the rate of rotation per second of the disc and the number of holes in the circle that is being used, we can readily calculate the *frequency* of the musical note produced (see SOUND). By shifting the nozzle to bear upon a different circle of holes we get a different note for the same rate of rotation.

In Cagniard de Latour's siren the blast of air whose interruption gives the note also drives the siren. Fig. 1 shows the upper surface of the siren, SS, resting on the cover of the wind-chest, AA. In fig. 2 the instrument is shown in vertical section through the line *nn* of fig. 1. The blast enters by the pipe, BB. The cover of the wind-chest is pierced with exactly the same number of holes as the disc, the only difference being that the holes pierced obliquely in both disc and wind-chest cover are oppositely directed in their obliqueness, as shown at *a* in fig. 2. When the corresponding holes are in apposition the blast of air is driven through all the holes, and by its impact on the obliquely cut walls of the holes in the disc forces the disc round. This brings the unpierced part of the disc opposite to the holes in the cover, and the air is cut off until the holes again come into apposition. The stronger the blast the more quickly will the disc be driven and the higher the note produced. A much more powerful tone can be obtained from this form of siren than from Seebeck's, inasmuch as all the holes are used simultaneously. Von Helmholtz's Double Siren is a combination of two of these on the same axis, each siren, by a suitable arrangement of concentric rings of holes which can be closed or opened at pleasure, being able to sound four distinct notes, singly or simultaneously. It is an invaluable instrument for demonstrating the laws of beats and combination tones (see SOUND). Other forms of siren used in fog-signalling are described under LIGHTHOUSE.

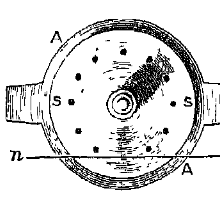


Fig. 1.

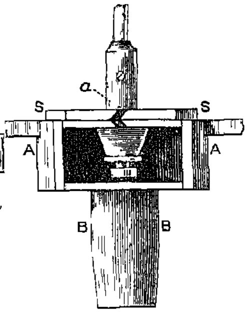

Fig. 2.

Sirenia, an order of aquatic mammals now represented by the dugong (Halicore) and the manatee (Manatus). Another form, Steller's sea-cow (*Rhytina stelleri*), was exterminated during the 18th century. In the Miocene and early Pliocene seas there seem to have been abundant Sirenians, many of which belonged to the genus Halitherium. As the characteristics of the dugong, the manatee, and Steller's sea-cow are described in separate articles, it is enough to state here that the Sirenians form a very distinct order, that in spite of their superficial resemblance they have certainly no near affinities with Cetaceans, that at present we must be content to regard them as old-fashioned and, it is to be feared, moribund types, occupying a lowly position in the Mammalian series. The name, which suggests mermaids, seems to refer to the appearance of the dugong, when it raises its head above the water or carries its young one under its arm.

Sirens, sea nymphs in Greek Mythology who sat on the shores of an island between Circe's isle and Scylla, near the south-western coast of Italy, and sang with bewitching sweetness songs that allured the passing sailor to draw near, but only to meet with death. In Homer there are two, in later writers three, Ligeia, Leukosia, and Parthenope, or Aglaopheme, Molpe, and Thelxiepeia. If any seaman could resist the enticements of their magic music they themselves were doomed to die, but Ulysses or the Argonauts alone succeeded in doing so. In the *Odyssey* we read how Ulysses, by the advice of Circe, stopped the ears of his companions with wax, and lashed himself to a mast, until he had sailed out of hearing of the fatal songs. The Argonauts got safely past because Orpheus protected them by the stronger spell of his own singing, whereupon the sirens threw themselves into the sea and were transformed into rocks. The Latin poets give them wings, and in works of art they are often represented as birds with the faces of maidens, and are provided with musical instruments. According to J. P. Postgate (*Cambridge Journal of Philology*, vol. ix.), the original meaning of the word is 'bird.' In later days they are represented on tombs as singers of dirges for the dead, and more generally as symbolising the magic power of eloquence and song. Parallel conceptions are the Mermaid (q.v.) of western Europe and the Lorelei (q.v.) of the Rhine. See Miss Harrison's *Myths of the Odyssey in Art and Literature* (1881).

Sirhind, a tract in the Punjab, being the north-eastern part of the plain between the Jumna and the Sutlej, which is watered by the great Sirhind Canal (main branch finished in 1882) and its branches. Sirhind, which is not an administrative division, contains five British districts (one being Umballa) and nine native states (including Patiala). It is named from an ancient town in Patiala, now in ruins.

Sir-i-kol, a great lake of the Pamir (q.v.).

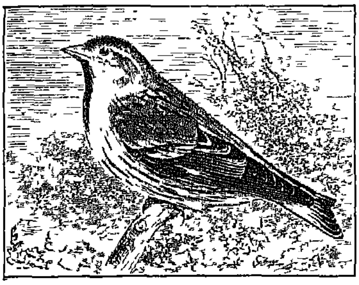
Sir-i-pul, a river, city (75 miles NE. of Maimana; pop. 15,000), and district in Afghan Turkestan.

Sirius, otherwise called *Canicula*, or the *Dog-star*, the brightest star in the heavens, is situated in the constellation of *Canis Major*, or the 'Great Dog.' Its distance in light-units is 8·6 (see STARS). It has long been known to possess a 'proper motion' —i.e. an independent progressive motion—which was for a time believed to be in a straight line, but was in 1844 shown by Bessel to consist of an undulatory progressive motion on each side of a middle line. This motion was investigated by Professor Peters of the Pulkowa Observatory, Russia, on the supposition that its anomalous character was produced by the attraction of some unseen neighbour, and his calculations were completed and verified by Mr Safford of Washington. In January 1862 Mr Alvan Clark of New York, chancing to observe Sirius through a powerful telescope, detected a minute star (which had never before been observed) situated at an angular distance of 7″ from Sirius, and it is generally believed that this is the disturber in question. By photometric measurement it has been shown that, adopting the latest measures of its distance, Sirius gives seventy times as much light as our sun would at the same distance, and has a mass three times that of the sun. The Egyptians called this star Sothis, and at one time its 'Heliacal Rising' (q.v.) was regarded as a sure forerunner of the rising of the Nile; while among the Romans it was considered a star of evil omen, whose appearance above the horizon coincided with (or even caused) the unhealthy and oppressive heats of summer. Hence the origin of the various superstitions regarding the Dog-days (q.v.), many of which are still current. The term 'dog-star' was also applied to Procyon, a bright star in *Canis Minor*, whose heliacal rising differs only by a few days from that of Sirius.

Sirocco, a name given in Italy to a dust-laden dry wind coming over sea from Africa; but also applied to any south wind, often moist and warm, as opposed to the Tramontana or north wind, from the hills.

Sisal Hemp. See FIBROUS SUBSTANCES.

Siskin (*Chrysomitris*), a genus of perching birds belonging to the family Fringillidæ, the true finches. The best-known species is the Common Siskin (*C. spinus*), which occurs from Britain eastward to Japan. This species breeds in the centre and north-east of Scotland, and is a familiar winter visitor to England and Wales. It is also common in some parts of Ireland. The siskin usually builds its nest, which is made of twigs and roots lined with moss, high in the branches of fir and birch trees. Two broods are reared in a season. The prevailing colour is yellowish green, with yellow and black markings on the upper and white on the under surface. The female is altogether dingier in hue than the male. The siskin is a common cage-bird, and will even breed in confinement, but the young are not easily reared.



Siskin (*Chrysomitris spinus*).

Sismondi, JEAN CHARLES LÉONARD SIMONDE DE, a historian of Italian descent, was born at Geneva on 9th May 1773. The outbreak of the French Revolution ruined his father and drove the family into exile, first to England, then to a small farm near Lucca; but in 1800 Sismondi himself went back to Geneva, and, having obtained certain municipal offices, applied himself to his favourite literary pursuits. He was introduced to Madame de Staël, and became one of the intimates of her circle, like Benjamin Constant and Schlegel. Whilst in the company of this lady he formed the beginning of a fast friendship with the celebrated Countess of Albany, widow of the Pretender and mistress of Alfieri. His *Histoire des Républiques Italiennes du Moyen-Âge* (16 vols. 1807-18) placed him in the first rank among contemporary historians. The events of the Hundred Days brought about one of the most memorable passages in his life—an interview with Napoleon. In 1813 appeared his *Littérature du Midi de l'Europe* (Eng. by Roscoe); and in 1819 he began his second great work, *Histoire des Français*, with which he was occupied until his death. As a historian Sismondi was distinguished more for industry than for natural gifts or graces of style. He took a lifelong interest in political economy: his first book on this subject, *De la Richesse Commerciale* (1803), is written from the standpoint of the *Wealth of Nations;* but in a later book, *Nouveaux Principes d'Économie Politique* (1819), he modified his views so far as to adopt a more decidedly moral or socialistic attitude. Amongst other products of his unwearying industry and perseverance may be named *Histoire de la Renaissance de la Liberté en Italie* (2 vols. 1832), *Histoire de la Chute de l'Empire Romain* (2 vols. 1835), and an abridgment (1839) of the twenty-nine volumes of his *Histoire des Français*. Sismondi died at Chène near Geneva on 25th June 1842.

See *Quarterly Review*, September 1843; *Vie et Travaux de Sismondi* (Paris, 1845); Sainte-Beuve's *Nouveaux Lundis* (vol. vi.); and collections of his own *Letters Inédites* (1863 and 1878).

Sissoo Wood. See ROSEWOOD.

Sisterhoods. All societies or communities of women living together under a religious rule, binding upon all, and with a common object for their united life, may be called Sisterhoods in the largest sense of the term. But in common use the word denotes those communities which are not enclosed, and whose life is one of active labour. An account of the great religious communities of women in the early and middle ages of Christianity falls under the head of Monachism. Indeed the state of Christendom for many centuries prevented the possibility of life and work for women such as that of Sisters of Charity. Women were affiliated to the great monastic orders, the Benedictine, Augustinian, Carmelite, &c., but, with one partial exception, that of the Hospitallers, 'Religieuses Hospitalières,' were invariably cloistered. There were several communities of hospital nuns, the great hospitals of the Hôtel Dieu at Paris, San Spirito at Rome, Dijon Hospital, and several others in France being served by them. But they lived in convents adjoining the hospitals, and only left their cloisters to nurse the sick. Even when the Franciscan and Dominican orders of preaching friars arose, the nuns belonging to them, the Poor Clares and Dominican nuns, were strictly enclosed. Their members might and did exercise the most powerful influence on society and education—nay, as in the case of a St Teresa or St Catharine of Sienna, on theology and politics—but this was through the force of moral and religious excellence, and sometimes of genius.

It was the glory of St Vincent de Paul to found, in 1633, assisted by Madame Le Gras, the first superior, the Society of 'Filles de la Charité,' and to lay the foundation of all modern religious communities who lead an active life devoted to various works of charity. The great need of such a society had become so obvious that the holy see, which had hitherto discouraged every attempt of a kindred character, solemnly approved of 'The Daughters of Charity' in 1655. In their constitution it was enacted that the community was 'to consist of girls, and widows unencumbered with children, destined to seek out the poor in the alleys and streets of cities.' In their founder's words, they were 'to have for monastery the houses of the sick; for cell, a hired room; for their chapel, the parish church; for their cloister, the streets of the town or wards of the hospital; for enclosure, obedience; for grating, the fear of God; for veil, holy modesty.'

The order spread with wonderful rapidity, and now numbers between 30,000 and 40,000 sisters, with two thousand houses over the world, devoted to every conceivable work of charity. Outside of France they have houses in Algeria, Belgium, Austria, the British Isles, Italy, Russia, Poland, Portugal, Spain, Switzerland, the Levant, Palestine, China, the United States, Guatemala, Panamá, Ecuador, Peru, Brazil, La Plata, Chili. In 1891 they undertook the care of a hospital at Jerusalem, at the request of the pasha, by whom at its opening they were received with great ceremony.

All are in connection with the mother-house, Rue de Bac, Paris, and are under the superioress, who is elected every three years, and who resides there. After five years' probation the sisters take vows, renewable every year. Their habit is gray-blue cloth, with large white collar, and white *cornette* for the head.

After St Vincent de Paul's sisters, the 'Petites Sœurs des Pauvres' rank next in numbers and in variety of active labours. They were founded in 1840 at St Servan, in Brittany, by the Abbé le Pailleur, then but twenty-five, and a young girl, Marie Jamet, a poor needle-woman. She was soon joined by another poor girl, Virginie Tredaniel, scarcely sixteen, and shortly after by an old servant, Jeanne Jugan, whose name is now known throughout the length and breadth of France, and who at forty-eight had saved 600 francs (£24). The institute was formed for the special object of the care of the aged, destitute, and sick poor. The work was begun by receiving a blind old woman of eighty in an attic, belonging to a poor woman, Fanchon Aubert, who at sixty years of age gave all she had to the work and lived with the sisters, though not formally joining the institute—then supported, as it still is in great measure, by scraps of food and other alms which the sisters begged day by day from house to house. At the present day, in all their houses, coffee-grounds form in the hands of the Little Sisters the basis of a beverage which is esteemed a delicacy by their old people.

Jeanne Jugan received from the French Academy the 'prize for virtue,' i.e. a grant of 3000 francs (£120) awarded every year to the person who is judged to have surpassed all others in works of charity. The recipient is said to be 'crowned by the French Academy.' This sum was applied to building their first house at St Servan, the Abbé le Pailleur selling his gold watch and other effects to help them; and the work begun thus humbly half a century before had by 1892, when the venerable founder and Marie Jamet (then mother-general) were still living, become one of the most imposing and important charitable institutes of our time, possessing 270 houses, with 4400 sisters. The mother-house, established at La Tour in 1856, contains 600 novices from all parts of the world; and from this single centre are directed the work of their thousands of sisters and the affairs of their houses all over France, besides those in Germany, Italy, Spain, Portugal, Belgium, the British Isles, Sicily, America, Africa, India, Ceylon, and Australia. The institute was definitively approved by Leo XIII. in 1886—the object, 'the care of aged people of both sexes, irrespective of creed.'

The 'Sœurs de Bon Secours' (of Troyes) were also founded in 1840, by Abbé Miller, canon of the cathedral at Troyes, for the purpose of nursing the sick in their own homes. There are now 115 houses of this 'congregation' in Europe, seven in Africa, and one in New York. In time of war the sisters nurse the soldiers on the battlefield and in the ambulances. There is another order of 'Bon Secours' Sisters (of Notre Dame), founded in 1824 by Archbishop Quélen.

A heroic sisterhood was formed in 1868 by Cardinal Lavigerie, called 'of the African Mission,' for the care of 300 Arab orphans after the great Algerian famine. They have been pioneers of civilisation as well as Christianity, ploughing and planting vineyards with their own hands, and in 1892 had eleven different houses scattered throughout northern Africa—among the Kabyle Mountains, on the edge of the desert, and along the coast of Algeria. One of their chief works is the reception and education of negro children rescued from slave-dealers. In July 1891 three of these sisters were brought, at the request of the king of Dahomey, to visit him; they were received with great pomp, and sent away with large presents, amongst which were three girls between ten and fifteen. Many other smaller societies of sisterhoods devoted to the care of the poor exist abroad; but, after France, Ireland has by far taken the lead, both in the rapid growth of such societies and in the number of women she has given to the work. Indeed, considering the smallness of her population, 4,700,000, she has probably far surpassed every nation in Europe in this charitable work.

During the prevalence of the penal laws in Ireland it was impossible for a woman in the dress of a sister to be seen in the streets. But on their repeal in 1782 and 1793 the fire of charitable enthusiasm in Irishwomen broke out and spread the more rapidly for its long repression. The 'Irish Sisters of Charity' were founded in Dublin in 1815 by Mary Aikenhead, daughter of a gentleman of good Scottish family who had settled in Cork. The society is on the same lines as that of St Vincent de Paul, but entirely distinct from it. They have now nearly 500 sisters, with twenty-three houses in Ireland, and one in England, besides four houses in Australia not depending on the mother-house. They are occupied in almost every kind of charitable work—orphanages, hospitals, penitentiaries, schools, convalescent homes, blind asylums, and certified industrial schools for girls under government, of which 4121 girls were inmates in 1890. A hospice for the dying at Harold's Cross near Dublin, with 200 beds, open to all denominations and perfectly free, must be visited in order to gain any notion of the beauty and comfort with which the dying are surrounded, and the perfection of every arrangement.

The other great sisterhood in Ireland is that of the Sisters of Mercy, founded in 1831 in Dublin by Catharine M'Auley. The object of this institute is 'all works of mercy, corporal and spiritual, especially education.' There are now at least 500 houses of these sisters in existence in all parts of the world. In their jubilee year, 1881, 168 houses had been founded in Ireland alone. This is quite the most remarkable development of an order of sisters in the world, considering that the whole population of Ireland is less than that of London.

Of sisterhoods belonging to the Anglican communion the first foundation was made in 1845 by Dr Pusey and Lord John Manners (afterwards Duke of Rutland), who, assisted by a few friends, opened a small house in Albany Street, Regent's Park, to receive a few women desiring to devote themselves to charitable works. Since then the spread of English sisterhoods has been scarcely less rapid than that of their Roman sisters in Ireland. The most powerful impulse to the movement was given by an Irish lady, the Hon. Harriet O'Brien, sister of Lord Inchiquin, who, having married the Rev. C. Monsell, and being early left a widow, undertook the charge of an infant community which had opened a House of Mercy for the reception of penitent women at Clewer, near Windsor, under the care of the rector of Clewer, the Rev. T. T. Carter, the venerable warden that was to be of the immense community numbering hundreds of sisters which has grown up under his fostering care. The sisters are engaged in all kinds of charitable works—missions in the worst parts of London, schools both for the poor and those of a higher class, and have built splendid convalescent hospitals, receiving both men and women, at Clewer, at Folkestone, and at Torquay. They have now five houses for different objects at Clewer, fourteen in London, and fourteen in other parts of England. They have also a branch in America, of which the mother-house is at New York; and in Calcutta they have charge of the Lady Canning Home, the nursing of the European General Hospital and of the Medical College and Eden Hospitals; also of the Pratt Memorial School, the European Orphan Asylum, and the hospital at Darjeeling, &c.

St Peter's Home, Mortimer Road, N.W., rivals the hospice for the dying near Dublin in the beauty and comfort of all arrangements that may cheer and comfort the dying. It is in England a unique home in this respect, and receives, besides the dying, patients needing long and tender care, incurables, infirm old women, ladies, especially for operations, &c. The sisterhood of St Peter's was founded in 1861 by the late Benjamin Lancaster, Esq., and his wife. The sisters have several other houses, including a convalescent hospital on the high heath and pinewood grounds above Woking Station. They also have mission houses under the parochial clergy in three parishes in the east of London and at Sydenham.

The first sisterhood in England, that founded by Dr Pusey, was broken up in 1855, after the war in the Crimea, where some of the sisters had worked under Florence Nightingale. A few of the original members of this first English sisterhood joined a small community which had been founded by Miss Lydia Sellon in 1849, called the Society of the Holy Trinity. The sisters have a house at Plymouth for lower and middle class schools, and a penitentiary; also a fine convalescent hospital and orphanage near Ascot, and a school at Honolulu, Hawaian Islands. They also work amongst the poor in Spitalfields.

One of the largest and most important sisterhoods in England was founded in 1851 under the title of 'Sisters of the Poor,' by the late Miss Harriet Byron. Their headquarters is All Saints' Home, in Margaret Street, but they have now eleven houses in London, besides the entire nursing of University College Hospital; thirteen all over England, including a splendid convalescent home at Eastbourne; one at Edinburgh; six in America; five at Capetown, besides the charge of New Somerset Hospital; and at Bombay the nursing of three hospitals and the care of two government schools.

St Margaret's Sisterhood was founded at East Grinstead in 1854 by the Rev. Dr J. M. Neale (q.v.) for the purpose of nursing the sick poor or rich in their own homes. They have fulfilled this object in all parts of England, and in the poorest cottages, and have also undertaken almost every other charitable work. They have, including daughter-houses depending on their own resources, thirty-two houses in England and Scotland; one at Boston, U.S., with sixteen branch houses; and an orphanage and mission-work at Colombo. They also work under the clergy in five London parishes.

The Holy Cross sisterhood, whose headquarters are at Holy Cross Home, Hayward's Heath, was formed in 1857 to aid in the St George's Mission-work, under the Rev. Charles Lowder, a task in which they persevered during twenty years of hand-to-hand fight with the heathenism of Ratcliffe Highway. They have still a branch house at St Peter's, London Docks, and others at Charlton, Dover, Winchester, and York, besides an orphanage and large training-school at Hayward's Heath, Sussex. One of the most flourishing sisterhoods in England—that of St Mary's, Wantage—was founded by the Rev. Dr Butler, afterwards Dean of Lincoln, primarily for penitentiary work. Like other societies, its objects have multiplied, and now embrace hospital-nursing, schools, mission-work, &c. Seventeen houses in London and various parts of England, a mission at Poona, India, with the government high school, the Sassoon Hospital, an orphanage for natives, a government native school, and a high-caste native school, are under the Wantage Sisters' care. The 'Sisters of Bethany,' founded in 1866, have their headquarters in Clerkenwell, and are chiefly devoted to education and to mission-work in poor parishes. They have six houses in London, two at Brighton, one at Shirebrook, Derbyshire, and an orphanage for a hundred children at Bournemouth. St Raphael's Sisterhood, Bristol, founded in 1867, follows, as far as possible, the rule of St Vincent de Paul, and is devoted entirely to the service of the poor; middle-class education and penitentiary work being excluded. Nine mission-houses, convalescent homes, &c. are under the care of the forty sisters and novices, of which five are in or near Bristol, one at Leeds, and one at Magila, Central Africa, in connection with the Universities Mission.

The 'Sisters of the Church,' Randolph Gardens, Kilburn, founded in 1870 by Miss Emily Ayckbowm, developed with extraordinary rapidity, as regards the number of sisters, now nearly 150, the immense number and variety of its work, and the large scale upon which each separate branch is carried on. Their prime object was to rescue girls from workhouse upbringing; and beginning with two little orphans in 1875, they have now 500 girls under their care, admitted without vote or payment, their only passport being entire friendlessness and destitution. In 1884 they opened an orphanage for forty boys at Brondesbury, and in 1886 a convalescent home for 300 children at Broadstairs. Their houses are spread over all parts of London and over England, education and mission-work being amongst their chief objects. They have a large publishing establishment in Paternoster Row; and one of their monthly publications—the *Banner of Faith*, begun in 1882—has a circulation of 320,000. They have immense schools, teaching many thousands of children, and training-homes for teachers. It would be impossible to enumerate all their works in connection with mission-work: restaurants for working-men, a night refuge for men, food-trucks for the unemployed, depôts for the sale of second-hand clothing, and an accident hospital at Rotherhithe. Two houses and schools have been founded by these sisters in Canada, and one at Madras.

Besides these large communities there are many smaller sisterhoods in England: (1) All Hallows, at Ditchingham, the sisters' chief work being amongst fallen women. They have a rescue hospital and another house at Norwich, and an orphanage, county hospital, and training-school at Ditchingham; also a branch in British Columbia. (2) Sisters of the Holy Name, founded 1865, working in the parish of St Peter's, Vauxhall, and with houses at Wednesbury, Malvern Link, Birmingham, and Worcester. (3) St Katharine's, at Fulham, founded 1879, their special object being prison rescue work. (4) St Laurence's Sisterhood, Belper, for the care of the helpless, and to nurse the sick. The sisters have a middle-class school, cottage hospital, and mixed school; also houses at Derby and Scarborough. (5) St Agnes' Sisters, Birmingham. (6) St Mary's Sisters, Brighton, in charge of penitentiary, industrial school, orphans, schools, &c. (7) St Michael's Sisters, Bussage, who have charge of the Diocesan House of Mercy. (8) St Peter's Sisterhood, Horbury, in charge of a penitentiary for seventy-five inmates, and with branch houses near Boston and Manchester. (9) Sisters of the Holy Rood, at North Ormesby, in charge of a cottage hospital for accidents, and two other small hospitals in the mining districts; also of a home for girls. (10) St Thomas' Sisterhood, Oxford, in charge of three schools of different grades, a penitentiary at Basingstoke, and an orphanage at Southsea. (11) St Denys' Sisterhood, Warminster, formed to train women for foreign missionary work. The sisters have a cottage hospital and ladies' school, and a school at Murree in the Punjab.

The first Protestant sisterhood in America was organised in 1852 by the Rev. W. A. Muhlenberg, rector of the church of the Holy Communion, New York, and author of the hymn 'I would not live alway.' The sisters took charge of St Luke's Hospital, which he founded in 1859.

Of most of the Anglican sisterhoods an accurate list will be found yearly in the *Kalendar of the English Church* (Burleigh Street, Strand). *St Margaret's Magazine* (Skeffington & Son), published every January and July, gives an account of the increasing works of the East Grinstead Sisterhood; and a monthly record is given by the 'Sisters of the Church' in *Our Work* (6 Paternoster Row). From the *Catholic Directory*, published in Dublin, New York, &c. every year, information can be obtained as to the spread of Roman Catholic sisterhoods. For Protestant deaconesses, see DEACON.

Sistine Chapel. See ROME, p. 785.

Sis'tova, a town of Bulgaria, on the south bank of the Danube, about 35 miles above Rustchuk. It carries on tanning, cotton-weaving, and wine-growing, and does a large trade in cereals. Here peace between Austria and Turkey was concluded in 1791; the Russians burned the place in 1810, and crossed the Danube into Bulgaria close by in 1877. Pop. (1887) 12,482.

Sistrum. See EGYPT, Vol. IV. p. 237.

Sisyphus, in Greek Mythology, son of Æolus, father of Glaucus, and husband of the Pleiad Merope; only in post-Homeric legends, from his cunning, the father of Odysseus. He is said to have been founder and king of Ephyra, afterwards Corinth, and both he and his whole house were notorious for their wickedness. Homer does not give the reason for his punishment in the lower world, but some later accounts make it his disclosure to the river-god Asopus that it was Zeus who had carried off his daughter; others, his wholesale robbery and murder of travellers. He was condemned to roll an immense stone from the bottom to the summit of a hill, which, whenever it reached the top, rolled down again, and so the task of Sisyphus had to be begun anew.

Sitapur, a municipality with 18,544 inhabitants in Oudh, 52 miles NW. of Lucknow. The place has a cantonment, and is the headquarters of a district, and gives name also to the north-western division of Oudh.

Sitka, the capital of Alaska, is on the west coast of Baranof Island, a deep harbour dotted with islands in front, and snow-clad mountains rising behind. Its principal buildings are the Greek church and the old Russian palace, now a storehouse. The climate, though not severe, is cold; oats cannot ripen here. The rainfall is 84–86 inches; 100 fair days mean an exceptionally fine year. Pop. (1890) 1188, including 859 Indians and 31 Chinese.

Sitten. See SION.

Sittingbourne, a brick-making market-town of Kent, on Milton Creek, 11 miles ESE. of Chatham and 45 of London. In olden days it was a great halting-place for Canterbury pilgrims and for kings and others on their way to the Continent. Pop. (1851) 2897; (1891) 8302.

Sitting-Bull (1837–90). See SIOUX.

Siva (a Sanskrit word, literally meaning 'happy,' 'auspicious') is the name of the third god of the Hindu Trimúrti (q.v.) or triad, in which he represents the characters both of Destroyer and Reproducer. The name Siva, as that of a deity, is unknown in the Vedic hymns, but established as such in the epic poems, Puránas and Tantras. The *Saivas*, or worshippers of Siva, assign to him the first place in the Trimúrti; and to them he is not only the chief deity, but the deity which comprises in itself all other deities. Thus, in the Siva-Purána, he is addressed as Brahma, Vishnu, Indra, Varuna, as the sun and the moon, as earth, fire, water, wind, &c.; but even in the Puránas relating to Vishnu his power is exalted in praise, and he is addressed with the utmost awe. The symbol of Siva is the Linga (q.v.), emblematic of creation, which follows destruction. From each of his numerous attributes or characteristics he derives a name or epithet. He has five heads (hence his name *Panchánana*, 'the five-faced'); three eyes (hence his name, *Trinetra*, &c., 'the three-eyed'), one of which is on his forehead, and indicates his power of contemplation; and in the middle of his forehead he wears a crescent. His hair is clotted together, and brought over the head so as to project like a horn from the forehead. On his head he carries the Ganges, whose course he intercepted by his hair, when this river descended from heaven, so as to enable the earth to bear its fall. Round his neck he carries a garland of human skulls. In his hands he holds the trident, a club or pole, armed at the upper end with transverse pieces, representing the breastbone and ribs adjoining, and surmounted by a skull and one or two human heads. Siva is doubtless a combination of an Aryan god and a non-Aryan deity—his wild and terrible attributes being doubtless derived from the pre-Aryan indigenous belief. Among his weapons are a bow, a thunderbolt, and an axe. As the destroyer of the world, he is also called Kála ('Time' or 'Death'), and represented as of black colour. One of his representations is also half-male and half-female, emblematic of the indissoluble unity of the creative principle. He is clothed in a deer-skin; or he also holds a deer in one of his hands; or he sits on a tiger-skin, or is clothed in it. When he rides, the bull Nandi is his beast of burden, whom he also carries as an emblem in his banner. He resides on the wonderful mount Kailása, the northern peak of the Himalaya, where he also rules over the north-east quarter. His principal wife is variously called Devi, Durgá, Umá, and Kálí, and is the great goddess of modern worship. One of his chief attendants is Tandu, who is one of the original teachers of the arts of dancing and mimicry, whence Siva is the patron of dancers. Besides Tandu, a host of other attendants and companions, together with demons and other beings, surrounding him, are named by the Puránas. Amongst the principal achievements of this god is his conflict with the god Brahma, who was originally possessed of five heads, but lost one through exciting the anger of Siva by disrespectfully addressing him. Siva is especially worshipped under the symbol of the Linga; but there are periods at which homage is paid to him also under other forms, corresponding with the description given above. Siva and Vishnu are nowadays in their male and female forms practically the gods of the Hindu population. Like Vishnu, Siva has a thousand names by which he is addressed; some derived from his exterior attributes have been mentioned before; among the others the principal are Isa or Iswara ('lord'); Mahesa or Maheswara ('the great lord'); Sankara ('the conferrer of happiness'); Rudra ('the terrible'), or Mahárudra ('the very terrible'); and Mahádeva ('the great god'). See INDIA, Vol. VI. p. 106.

Sivaji (1627–80), the founder of the Mahratta power in India. See MAHRATTAS.

Sivas, a city of Asiatic Turkey, is situated on the Kizil Irmak (anc. *Halys*), 170 miles SW. of

Trebizond, and is a dirty, decayed place. Pop. 15,000, of whom about 3000 are Armenians, the rest Turks. It is built on the site of the ancient *Sebasteia*, from which it derives its name.

Siwah. See OASES.

Siwalik Hills. See HIMALAYA, Vol. V. p. 716.

Siwash, or PUTRID SEA. See CRIMEA.

Six Acts, six repressive measures passed in England in 1819 to prevent seditious assemblies and unauthorised military training, punish seditious libels, increase the power of the magistrates, and further restrict the liberty of the press. They were very unpopular, and are known as the 'Gagging Acts.'

Six Articles, STATUTE OF, an enactment of Henry VIII. (1539), commonly called the Bloody Statute, to compel the uniform profession of the following six doctrines: (1) The Real Presence of Christ in the Eucharist, and Transubstantiation; (2) the sufficiency of communion in one kind only; (3) the unlawfulness of the marriage of priests; (4) the obligation of vows of chastity; (5) the propriety of retaining private masses; (6) the expediency and necessity of auricular confession. In spite of the threatened penalties, only twenty-eight persons suffered death under the statute throughout the whole reign. See HENRY VIII.

Six Nations. See IROQUOIS.

Sixtus, the name of five popes, of whom two call for particular notice, Sixtus IV. and Sixtus V. The former (originally named Francesco della Rovere), born July 22, 1414, was the son of a fisherman in Celle, a small village near Savona. He was a pupil and friend of the celebrated Cardinal Bessarion, and, having entered the Franciscan order, gained the highest reputation throughout Italy as a preacher. On the death of Paul II. in 1471, Rovere, who had risen to be general of his order, was elected to the Roman see. His inordinate partiality for his relatives exhausted the papal treasury, and led to many questionable exactions, and to gross abuses in the dispensation of church patronage. But the worst imputation upon his memory is his connivance in the Pazzi conspiracy against the Medici (q.v.) at Florence. In many respects, however, his administration was liberal and public spirited. He did much to foster learning and to encourage art, and contributed notably to the improvement and decoration of the city. He built the Sistine chapel and the Sistine bridge across the Tiber, took a zealous interest in augmenting the Vatican library, and was a munificent patron of the great painters of the day. In 1482 he entered into an alliance with the Venetians against the Duke of Ferrara, which led to a general Italian war, and ended in a dissolution of the Venetian alliance, an event so mortifying to the pope that his death is said to have been caused by chagrin, August 13, 1484. His successor was Innocent VIII.—SIXTUS V., one of the most able and vigorous occupants of the Roman see, originally named Felice Peretti, was born (December 13, 1521) near Montalto, of poor parents. He early entered the Franciscan order, was made professor of Theology at Rimini and Sienna, won a great name as an eloquent preacher, and gradually rose, through the offices of inquisitor-general in Venice and vicar-general of the Franciscan order, to be cardinal (Cardinal Montalto) in 1570. Shortly after the accession of Gregory XIII. (1572) he began to lead a retired and mortified life, and was believed to have fallen almost into the decrepitude of age and infirmity. This circumstance seems to have recommended him to the cardinals assembled to elect a successor to Gregory in 1585. But Sixtus totally deceived those who had thought to lead him; for his rule was most active and energetic, and was marked by vigorous measures of improvement in every department of administration, ecclesiastical as well as civil. His first care was to repress the prevailing license and disorder of the city of Rome, and of the papal states generally, by breaking up the bands of outlaws by which both were infested. He reformed the administration of the law and the disposal of public patronage; and he entered upon numerous projects for the moral and material improvement of Rome. Amongst others he erected the library buildings of the Vatican. He found an empty pontifical treasury; yet by judicious retrenchment, and heavy taxation, he secured within the first years of his short pontificate a surplus of above 5 millions of crowns. To the Jews (q.v., Vol. VI. p. 328) he extended full liberty to trade and celebrate their own worship throughout his dominions. The great aim of his foreign policy was to advance the cause of the Roman Catholic Church in every quarter of Christendom, against the Huguenots in France, against the Lutherans in Germany, and against Queen Elizabeth in England. At the same time he entertained a deep jealousy and apprehension of the designs of Spain. Amongst other reforms in church matters he fixed the number of the College of Cardinals at seventy, and reorganised the separate congregations of cardinals. Under his authority were published a new edition of the Septuagint and an edition of the Vulgate, the latter famous from the multiplicity of its errors, subsequently corrected in the edition of Clement VIII. Sixtus died on 27th August 1590, and was followed in the papal chair by Urban VII.

Many of the popular stories regarding him are derived from Gregorio Leti's *Vita di Sisto V.* (2 vols. Lausanne, 1669), a work of no authority. The best account is that of Ranke; and see also Tempesti, *Storia della Vita e Gesti de Sisto V.* (2 vols. Rome, 1754); Lorentz, *Sixtus V. und seine Zeit* (Mainz, 1852); and Baron Hübner, *Sixte V.* (Paris, 1870; Eng. trans. 1872).

Sizar, the name of an order of students at Cambridge and Dublin universities, so called from the allowance of victuals (*size*) made to them from the college buttery. Duties of a somewhat menial kind, such as waiting upon the fellows at table, were originally required of the sizars, but these have long since gone into disuse. At Oxford there was formerly a somewhat similar order of students denominated Servitors.

Size. See GLUE, and GELATINE.

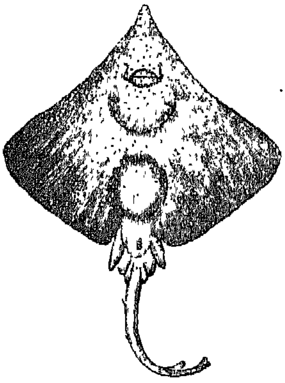
Skagen, CAPE, or THE SKAW, the most northerly point of Jutland, Denmark, on which is built a lighthouse of stone, 148 feet high. Near it is a small town of 1954 fishers and pilots.

Skager-Rack, an arm of the North Sea lying between Denmark and Norway, and communicating with the Cattegat, is about 140 miles long from WSW. to ENE., and 70 miles broad. The depth is much greater on the Norwegian than on the Danish coast, being on the former about 200 fathoms, while on the latter it varies from 30 to 40 fathoms. When free from violent storms—to which, however, it is very subject—the current runs east on the side next Denmark, and west on that next Norway, the harbours being all on the latter coast.

Skald signifies in old Norse a poet. The name was given specially to that class of poets who exercised their art as a vocation requiring a learned education—i.e. a knowledge of the construction of verse, and of the enigmatical imagery, roughly shaped out of obscure tradition, to which Scandinavian poets were prone. The principal aim of the Skaldic poetry was to celebrate the deeds of living warriors or of their ancestors. Very few complete Skaldic poems are extant; but there are a great number of fragments preserved, partly in the younger Edda (q.v.), partly in the Sagas (q.v.) and the Heimskringla. See SNORRI STURLASON.

Skaptá. See ICELAND, Vol. VI., p. 60.

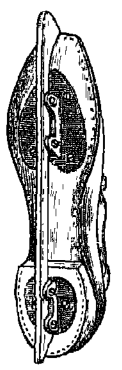
Skat, a game played with thirty-two cards as in Piquet (q.v.), and said to have been invented in 1817 in Altenburg, whence it rapidly spread into other parts of Germany and beyond the borders of the fatherland. Each of three players receives ten cards, the two others being laid aside (hence the name—from old French *escart*, 'laying aside'). The values of the cards and the rules of the game are expounded in numerous works—one in English by L. V. Diehl (Lond. 1891).



Common Skate (*Raia batis*).

Skate, the popular name of several species of Ray (q.v.). The Common Skate (*Raia batis*), known in Scotland as the *Gray Skate* and in the south of England as the *Tinker*, is plentiful on most parts of the British coasts. The Burton Skate (*R. marginata*) is another of the British species. On American coasts numerous species occur—e.g. on the east, the 'Tobacco-box' Skate (*R. erinacea*), the Briar-skate (*R. eglanteria*), the Smooth or Barn-door Skate (*R. lævis*); on the west, *R. inornata*, and the large *R. binoculata*, which attains a length of 6 feet. But a revision of the species of skate is necessary. Skates are voracious fishes, feeding along the bottom. Their egg-cases or mermaids' purses are often thrown up on the beach. They are often caught on the lines, but great numbers are now brought to market by the trawlers. The greatly expanded pectoral fins are eaten, but the flesh tends to be coarse.

Skating. Progression on ice is accomplished by means of instruments composed of steel blades which are fastened to the soles of the boot, and which are called skates. In early times the shin bones of animals were bound to the feet, and skaters glided over the frozen surface on these by propelling themselves with the aid of a spiked stick. At a later period the iron or steel blades were introduced, the cutting edge of which enabled the wearer to dispense with the stick, and to push off with one foot and glide on the other with alternate strokes. Stow tells how the London 'prentices used to 'tie bones to their feet and under their heels,' and by that means slide on the ice; and Evelyn, under date 1st December 1662, describes how 'divers gentlemen performed before their Ma$^{\text{ties}}$ on the new canal in St James's Park, with *Scheets* after the manner of the Hollanders.' Skates are now of two kinds—viz. those made for speed-skating and those for figure-skating. Both were formerly constructed by inserting the steel blade into a wooden bed, which was approximately shaped to the foot and bound to it by means of leather straps. Modern skates are made entirely of metal, and are fixed either by screws passing through plates (to which the blade is attached) into the sole of the boot, which form of skate is known as the Mount Charles; or they are fixed to the boot by various mechanical devices which enable the skate to be quickly and firmly attached to the boot, and as quickly removed. Of these the skate known as the Barney and Berry is the most reliable. Many speed-skaters continue to use the wooden bed-skate. The blades of skates for speed-skating are made very thin, about $\frac{1}{10}$th of an inch, somewhat longer than the foot, and very slightly convex along the whole length of that part of the blade which comes in contact with the ice. Speed-skating as a pastime has lately come greatly into vogue owing to the encouragement given to it by the National Skating Association, and the Fen men of the eastern counties of England not only beat all British competitors, but hold their own and frequently win at the international contests in Holland, Norway, and Sweden. Races on skates are brought off on tracks having one or more turns, and the fastest time for a mile with a standing start is, for professionals, 2 m. 52 s., by George See, and 2 m. 52$\frac{1}{5}$ s. by James Smart (both Englishmen), run on 17th February 1887, in Holland; and for amateurs, 2 m. 55$\frac{3}{5}$ s. by T. Thomas (a Swede), on 2d March 1890, at Stockholm. One mile on a straight course, with a very strong wind in favour, was skated at Newbury, U.S., on 1st February 1889, by T. Donoghue, in 2 m. 12$\frac{3}{5}$ s. The five-mile record for professionals was up to the end of 1891 16 m. 58 s., skated by Hugh M'Cormick at Montreal in 1888; and for amateurs it is 16 m. 34$\frac{3}{5}$ s. by Jos. T. Donoghue, U.S., at Orange Lake, on 8th March 1890. On 29th December 1891 Harold Hagen, a Norwegian, competing against William Smart, the English champion, skated 5 miles in 15 m. 11 s. on Lake Mjorsen, Norway; and again, competing against Smart on 3d January 1892, did 3 miles in 8 m. 46$\frac{3}{5}$ s., and two miles, on 28th February, in 5 m. 43$\frac{4}{5}$ s. The ordinary travelling pace of Fen skaters is from 10 to 12 miles an hour.



The Mount Charles Skate.

Skates for figure-skating are broader and deeper in the blades, rounded at both toe and heel, and with a curvature along the whole length equal to that of a circle having a 7-foot radius. The Edinburgh Skating Club (1642) is the oldest club for encouraging figure-skating in Britain, but the figures skated were of an elementary character until after the formation of the Skating Club, London (1830). The members of this club instituted a series of combined movements known as 'The Skating Club Figures,' which have induced a mode of skating peculiar to Great Britain, consisting as it does of large and bold curves and turns, executed with great power and quietness, while the body of the skater is held upright, and the knee of the travelling leg kept quite straight. Figure-skating is now much practised in America, Canada, Holland, Germany, Norway, Sweden, and Denmark; but the nature of the skating in vogue is calculated to excite astonishment at the acrobatic dexterity displayed rather than pleasure at the grace and elegance of the gliding movement which should distinguish good figure-skating. The skates used for this style of skating have a radius of about 5 feet, and this curvature is given to the blade to facilitate the rapid turns and short curves which are practised in this mode of skating. At St Moritz, Davos Platz, and Grindelwald there are excellent ice rinks, much frequented during winter by English visitants.

Wheeled skates were in use on roads in Holland as far back as 1770; but it is only since the introduction of the circular running roller-skate, invented in 1865 by Mr Plimpton of New York, speed and figure skating have become common on roller-skates. Besides being a means of exercise taken under a fascinating form, roller-skating is a splendid introduction to ice-skating.

A bibliography of nearly 300 works relating to skating was printed in *Notes and Queries* between 1874 and 1881. The modern books on (1) Speed-skating are the Annual Reports of the National Skating Association; *Fen-skating*, by N. and A. Goodman (Sampson Low & Co.); *Speed-skating*, by N. Goodman ('All England' series); *Speed-skating*, by Heathcote and Tebbutt ('Badminton' series): and (2) on Figure-skating, *The Art of Skating*, by Cyclos (Horace Cox); *A System of Figure-skating*, by Vendervell and Witham (Horace Cox); *Skating Cards*, by W. Crossley (L. Upcott Gill); *Combined Figure-skating*, by Monier-Williams, Pidgeon, and Dryden (Horace Cox); *Skating*, by D. Adams ('All England' series); and *Figure-skating*, by the present writer ('Badminton' series). There is also a good German book, entitled *Spüren auf dem Eise*, by D. Diamantidi and others (A. Hölder, Vienna). For skating with sails, see the Badminton book, p. 213.

Skean-dhu. See DIRK.

Skeat, WALTER WILLIAM, a learned Early English scholar, was born in London, November 21, 1835, and educated at King's College School and Christ's College, Cambridge, graduating as fourteenth wrangler in 1858. He became Fellow of his college in 1860, and four years later Mathematical Lecturer there; filled for some time curacies at East Dereham and Godalming; in 1878 was elected the first Elrington and Bosworth professor of Anglo-Saxon at Cambridge, and re-elected to a Christ's College fellowship in 1883. He was the first director of the Dialect Society (established 1873), and he has contributed, by his exhaustive labours on Langland and Chaucer, and innumerable editions of Early English works, more than any scholar of his time to a sound knowledge of Middle English and English philology generally.

His most important books are the following: *Piers Plowman*, in its three texts (5 parts, 1867-85; re-issued by the Clarendon Press, 2 vols. 1886); *The Lay of Havelok the Dane* (1868); Barbour's *Bruce* (3 parts, 1870-77); Chaucer's *Treatise on the Astrolabe* (1872), &c., all edited for the Early English Text Society; an edition of Chatterton's *Poems* (2 vols. 1875); Chaucer's *Minor Poems* (1888); school editions, for the Clarendon Press series, of several of Chaucer's *Canterbury Tales*, a portion of *Piers Plowman*, and two volumes of *Specimens* of earlier English literature; the *Kingis Quair* (1884), for the Scottish Text Society; *A Mœso-Gothic Glossary* (1868); his great *Etymological English Dictionary* (1882), and its admirable abridgment, the *Concise Etymological Dictionary* (1882); and *Principles of English Etymology* (vol. i., The Native Elements, 1887; vol. ii., The Foreign Elements, 1891). His next task was the preparation for the Clarendon Press of a complete edition of Chaucer.

Skegness, a little watering-place of Lincolnshire, 22 miles NE. of Boston by a branch-line. Pop. 1488.

Skeleton, a general term for the more or less hard parts of animals, whether forming an internal supporting framework—an endoskeleton, or an external exoskeleton, often useful as armour. The term includes so many different kinds of structure and material that it is necessary to take a survey of representative types.

Skeleton of Invertebrates.—Many of the Protozoa have shells of lime (see FORAMINIFERA), or of flint (see RADIOLARIA), or of some organic substance, such as acanthin. These are formed by the living matter of the units, in the case of the lime and flint shells from materials absorbed from the surrounding water, but in what precise way we do not know. Almost all Sponges (q.v.) are supported by loose or firmly fused spicules of lime or of flint, or have, as in the bath-sponge, an interwoven supporting skeleton of 'horny' fibres. The spicules or fibres are formed by cells in the middle stratum of the sponge. Among Cœlenterates various forms of skeleton, both external and internal, both limy and 'horny,' are represented by the different kinds of Corals (q.v.). With few exceptions these skeletons are produced by cells belonging to the outer layer or ectoderm of the animal. Worms have little that can be called a skeleton, although some authorities would compare the sheath of the proboscis in Nemertea (q.v.) to the notochord of Vertebrates. The tubes, calcareous or otherwise, in which many sedentary worms are sheltered, have no vital connection with the animals which make and inhabit them. Echinoderms tend to be very calcareous; lime is deposited in the mesodermic tissue of the body in almost any part, though predominantly near the surface. Most Arthropods have well-developed exoskeletons, cuticles formed from the epidermis, consisting in great part of an organic basis of chitin, on which, in Crustaceans and most Myriopods, carbonate of lime is also deposited. As this cuticle is not always restricted to the outside of the animal, but sometimes extends inwards, an apparent endoskeleton arises—e.g. in the lobster, the king-crab, and the scorpion. Most Molluscs have shells in which carbonate of lime occurs along with an organic basis conchiolin, and in cuttle-fish there is a remarkable development of cartilage around the nerve-centres in the head—an analogue of the skull in Vertebrate animals. From this rapid survey it will be seen that the skeletons of Invertebrates are very varied alike in structure and in composition; if we except a few doubtful hints of a supporting axis, there are no homologies between the skeletons of Invertebrates and Vertebrates; to the latter, moreover, that form of tissue which we call bone is exclusively restricted.

Skeleton of Vertebrates.—Here we must distinguish first of all between the external exoskeleton and the internal endoskeleton. The scales of fishes, the scales and scutes of reptiles, the scales, claws, and even feathers of birds, the remarkable bony armature of armadillos, the scales of pangolins, the claws of carnivores, the quills of porcupines, and even the hair of ordinary mammals illustrate the variety of structures which may be included within the anatomical conception of an exoskeleton. All these structures are formed in the epidermis, or in the dermis, or in both combined. Tortoise-shell and the scales of reptiles are epidermic; the scutes of crocodiles and the plates covering armadillos are dermic; the scales of Elasmobranch and Ganoid fishes are due to both layers. But it is difficult to carry out any rigidly logical classification. Thus, the dorsal shield of a tortoise is physiologically an exoskeleton, but structurally it is in great part formed from the dorsal vertebræ and from what in other animals form the ribs. The ventral shield of a tortoise is formed from dermal bones, and the so-called abdominal ribs of crocodiles arise as ossifications in the fibrous tissue which lies underneath the skin and above the muscles. The teeth of Elasmobranch fishes are undoubtedly homologous with the dermal denticles or skin-teeth which occur over the skin, and the teeth of mammals are started by enamel germs which sink in from the epidermis of the mouth.

The Vertebral Column.—In a primitive Vertebrate animal like the lancelet the body is supported by a median dorsal axis, and, apart from slight supports for the mouth, the pharynx, and the median fin, this is all the skeleton. The median dorsal axis, which in the lancelet has not even the firmness of cartilage, is called the notochord, and is one of the constant characteristics of the skeleton of Vertebrates. There is a hint of it in the proboscis of Balanoglossus (q.v.) and in Cephalodiscus (q.v.); it is more distinct in the tail of young Ascidians (q.v.), and persists throughout life in Appendicularia; in the lancelet, in the hag, and in the young lamprey it is an unsegmented rod with a simple sheath; in the adult lamprey there are above the notochord rudimentary arches of cartilage forming a trough in which the spinal cord lies; in cartilaginous Ganoid fishes, such as the sturgeon, in the Chimæra type, and in the Dipnoi cartilaginous arches appear both above and below the notochord, but there are as yet no vertebral bodies. These begin in the Elasmobranch fishes, in which the notochord is, in part at least, constricted by the encroachment of its sheath, and divided into vertebræ. In the bony Ganoids, such as Lepidosteus, the vertebræ are ossified, and so they are more or less thoroughly in all the higher Vertebrates. Yet it is not the notochord which is ossified, but its sheath; the notochord in all higher Vertebrates being merely a provisional structure, an internal scaffolding around which its 'substitute,' the backbone, is built. Each vertebra generally consists of the substantial body or centrum, the neural arches which form a tube for the spinal cord and meet above it in a neural spine, the transverse processes which project laterally and are usually connected with ribs, and the articular processes which bind vertebra to vertebra so that a firm and yet flexible backbone results.

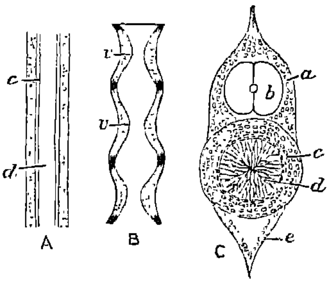


Fig. 1.

A, unsegmented notochord (*d*), its sheath (*c*). B, notochord in process of being constructed by its sheath, the parts marked (*v*) corresponding to the centres of two adjacent vertebræ. C, section of a young vertebral column: *d*, the notochord; *c*, its sheath; *b*, the spinal cord protected by neural arches (*a*); beneath are inferior processes (*e*).

A breastbone or sternum to which the ribs are ventrally united occurs in many Reptiles and in all Birds and Mammals. It arises from a cartilaginous tract uniting the ventral ends of the ribs. In Amphibians also there is a breastbone, but there are no distinct ribs, and it is not certain that we can compare this sternum with that of higher Vertebrates.

The Skull.—In a young Vertebrate animal the cavity in which the brain lies is surrounded by a membranous sheath, but this is gradually replaced, first by a gristly brain-box, and afterwards in most cases by an almost entirely bony skull. Let us first consider the gristly brain-box or chondro-cranium. (*a*) Its foundation is formed from two pairs of cartilaginous plates—posterior parachordals and anterior trabeculæ—which lie beside and in front of the notochord. These are extended upwards by a further formation of cartilage; the end of the notochord may also help a little: the result is a cartilaginous brain-box. (*b*) But to the sides of this are added a pair of cartilaginous nasal capsules in front, and a similar pair of auditory capsules behind. (*c*) About the mouth there are some lip or labial cartilages, which may help in forming the skull; but much more important is a series of cartilaginous 'branchial arches' (never more than eight pairs), which loop round the pharynx, running between the primitive gill-clefts. Of these arches the two most anterior, which are called the mandibular and the hyoid arches, are of great importance in the development of the skull; the others form supports for the pharynx, and are permanently important only in Fishes and in gilled Amphibians. In Elasmobranch fishes the mandibular and hyoid arches do not form any direct part of the gristly brain-box, but in the Teleosteans and thence onwards they, or the bones which replace them, contribute directly to the upbuilding of the skull. To follow the history of the arches, which undergo numerous transformations, is one of the most difficult and interesting tasks of comparative anatomy. (*d*) When a bone develops in direct relation to a pre-existent cartilage which it replaces, it is often called a primary or 'cartilage bone;' and there are many regions of the cartilaginous brain-box which in the course of development are thus replaced by bones. But there are other bones which develop independently of pre-existent cartilage. They invest the cartilaginous brain-box on its roof, on its floor, and on its sides. They are comparable to the dermal ossifications or scutes which occur in Ganoid fishes and many other animals, and they are often called secondary or 'membrane' bones. In structure they are of course indistinguishable from 'cartilage bones;' in origin too they are in one way the same, for all bones arise from a (periosteal) membrane of bone-making cells; but 'cartilage bones' are at one time represented by cartilages, whereas 'membrane bones' never are.

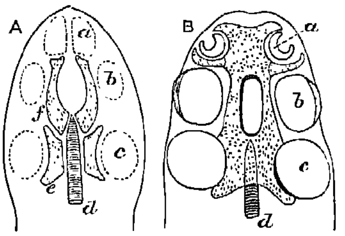

Fig. 2.

A, cartilaginous rudiments of the skull: parachordals (*e*), trabeculæ (*f*), anterior end of notochord (*d*), auditory capsule (*c*), optic capsule (*b*), nasal capsule (*a*). B, a slightly more advanced state; the nasal and auditory capsules have fused with the brain-box; the optic capsules remain free.

To sum up, the skull is formed (*a*) from the parachordals and trabeculæ at the end of the notochord, (*b*) from the adjacent sense-capsules of the nose and the ear, (*c*) from the more or less intimately associated mandibular and hyoid arches, (*d*) from the ossification of the gristly brain-box due to (*a*), (*b*), and (*c*), but also from 'membrane bones' or investing bones which arise independently of pre-existent cartilages. There is no skull in Tunicates or in the lancelet; it is cartilaginous in Cyclostomata and Elasmobranchs; centres of

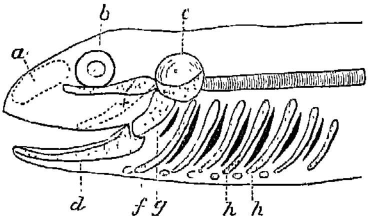

Fig. 3.—Diagram showing the branchial arches of the Embryo:

d and *g*, parts of first or mandibular arch; *f*, part of second or hyoid arch; behind these the arches (*h*) separating gill-clefts; *a*, *b*, *c*, the nasal, optic, and auditory capsules.

ossification and investing bones begin with the Ganoid fishes, and are numerous in Teleosteans and in all higher animals. In the development of the individual there is a parallel progress.

Theory of the Skull.—About the beginning of the 19th century Oken and Goethe independently suggested what is known as the vertebral theory of the skull—an undoubtedly suggestive theory, to which Owen lent the strength of his authority, but which has been disproved by the subsequent discoveries of comparative anatomy and embryology (see Skull).

The Appendicular Skeleton.—Somewhat apart from the axial skeleton are the limbs and the girdles to which these are attached. No secure conclusion has yet been reached as to origin of the limbs of Vertebrates. In the simplest forms—the Tunicates, the lancelet, the Cyclostomata—there are none, and there is a very marked difference between the fin-like limbs of fishes and the fingered and toed limbs which occur in almost all higher backboned animals. According to Gegenbaur, the pectoral and pelvic girdles are structures comparable to the branchial arches, and he supposes that the primitive limbs were made up of modified fin-rays comparable to those which support the unpaired fins of fishes. According to Dohrn the limbs are residues of a longitudinal series of segmentally arranged outgrowths, perhaps comparable to the appendages of a typical Annelid worm (see Fishes, Vertebrata).

The pectoral or shoulder-girdle consists of a dorsal shoulder-blade or scapula, a ventral coracoid, with the articulation for the arm between them, and of a forward-growing collar-bone or clavicle. The pelvic or hip-girdle consists on each side of a dorsal ilium, a ventral ischium, with the articulation for the leg between them, and of a third pubic portion. The fore-limb—from Amphibians onwards—consists of a humerus articulating with the girdle, a lower arm composed of radius and ulna lying side by side, a wrist or carpus of several elements, a hand with metacarpal bones in the palm and with fingers composed of several joints or phalanges. The hind-limb—from Amphibians onwards—consists of a femur articulating with the girdle, a lower leg composed of tibia and fibula lying side by side, an ankle region or tarsus of several elements, a foot with metatarsal bones in the sole and with toes composed of several joints or phalanges. Distinct from all the other bones are a few little ‘sesamoids’ which are occasionally developed within tendons and near joints, notably, for instance, the knee-pan or patella.

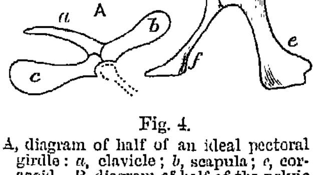

Fig. 4.

A, diagram of half of an ideal pectoral girdle: *a*, clavicle; *b*, scapula; *c*, coracoid. B, diagram of half of the pelvic girdle of an alligator: *d*, ilium; *e*, ischium; *f*, pubis.

The Skeleton of Man.—As the bones of all the chief parts of the human body are described in separate articles, we need not do more than unify these by reference to a diagram of the entire skeleton (fig. 5). Altogether there are more than 200 bones, but some which are originally distinct become fused with their neighbours.

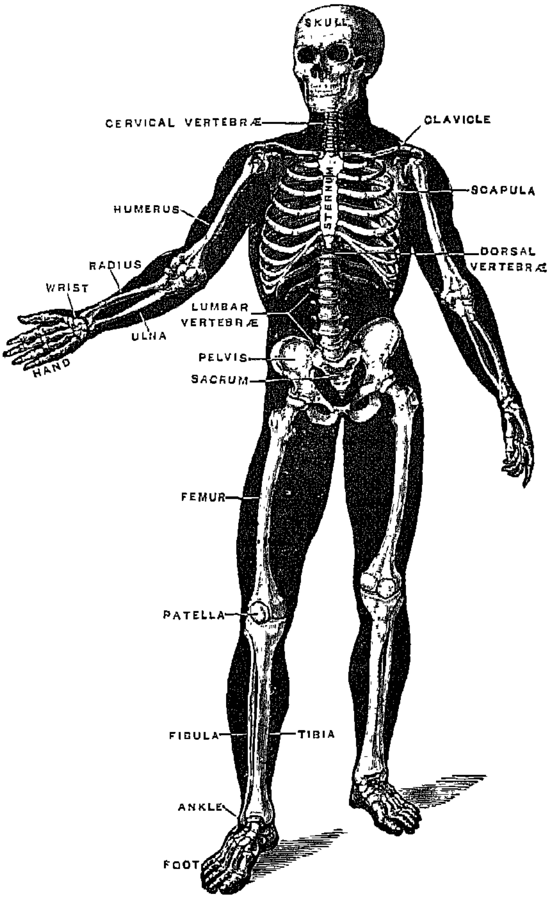

Fig. 5.—Human Skeleton.

In the vertebral column there are originally thirty-three vertebræ, but in adult life the normal number is twenty-six, for, while the first twenty-four remain distinct, five (the twenty-fifth to the twenty-ninth inclusive) unite to form the sacrum supporting the hip-girdle, and the four hindmost fuse more or less completely in a terminal tail-piece or coccyx. Seven cervicals support the neck; twelve dorsals form the greater part of the back and bear ribs; five lumbars occur in the loins; these are followed by the sacrum and the coccyx (see Spinal Column).

The ribs, or elastic arches of bone which bound the chest, are normally twelve on each side. Most of them articulate dorsally with the bodies of two adjacent vertebræ and with the transverse processes of the posterior one; ventrally the first seven pairs are connected with the median breastbone by means of intervening cartilages, while the posterior five pairs are more or less free (see Ribs).

The skull consists in early adult life of twenty-two separate bones, but originally there were more, and as life continues the number may be further reduced by fusion. For the various bones, see Skull.

The skeleton of the arm includes thirty bones—in the upper arm the humerus, which articulates with the shoulder-girdle; in the forearm the radius and ulna, which articulate with the humerus at the elbow; the wrist of eight carpal bones; the five metacarpals of the palm; the five digits, of which the four fingers have each three joints or phalanges, while the thumb has two. The important bone of the pectoral girdle is the shoulder blade or scapula. To this, at the shoulder joint, there is fused a small beak-like bone—the coracoid—which is separate in Birds and Reptiles, but reduced to a mere process of the scapula in all Mammals except the Monotremes. Stretching from the breastbone to shoulder blade is the curved collar-bone or clavicle.

The skeleton of the leg also includes thirty bones—in the thigh the femur, which articulates with the hip-girdle; in the lower leg the shin-bone or tibia and the splint-bone or fibula, which articulate with the femur at the knee-joint, where there lies a little 'sesamoid' bone—the patella; in the ankle region seven bones, then five metatarsal bones forming the sole of the foot, and five toes with the same number of phalanges as in the fingers. The pelvic girdle consists in early life of three paired bones—large dorsal ilium, a posterior ischium, an anterior pubis on each side—but these unite about the twenty-fifth year into single haunch-bone, with the socket of which the thigh articulates. See ARM, HAND, SHOULDER, FOOT, LEG, PELVIS, RIBS, SKULL, and SPINAL COLUMN; for literature, see the works referred to in the article ANATOMY. Skeletons other than human will be seen under the headings of ANTHROPOID APES, BAT, BIRD, ELK, FISHES, HESPERORNIS, ICHTHYOSAURUS, IGUANODON, MEGATHERIUM, PLESIOSAURUS, PTERODACTYL, &c.; and skulls at BABIROUSSA, CARNIVORA, DOG, RODENT, &c.

Skelligs, three rocky islands on the south-west coast of Ireland, lying 10 miles SW. of Valentia island. On one of the rocks stands a lighthouse, the light of which is 175 feet above high-water, and visible 18 miles at sea. On Great Skellig (710 feet high) are the ruins of a monastery.

Skelmersdale, a town of Lancashire, 4½ miles from Ormskirk. Pop. (1851) 760; (1891) 6627.

Skelton, JOHN, an early satirical poet, is supposed to have been born about 1460, most probably in Norfolk, although generally said to have been sprung from a Cumberland family. He studied at Cambridge, perhaps also at Oxford, and received from each the academical honour of laureate. He was appointed tutor to the young prince Henry, and early acquired such reputation for learning that Erasmus styles him 'the one light and ornament of British letters.' He took holy orders in 1498, and became rector of Diss in Norfolk, but seems later to have been suspended for keeping a concubine; although Fuller tells us how, on his death-bed he protested 'that in his conscience he kept her in the notion of a wife, though such his cowardliness that he would rather confess adultery (then accounted but a *venial*) than own marriage, esteemed a capital crime in that age.' Wood tells us that he 'was esteemed more fit for the stage than the pew or pulpit,' and Churchyard says 'his talke was as he wraet.' Already he had produced some translations, and elegies upon Edward IV. and that Earl of Northumberland murdered by a Yorkshire mob in 1489; but now he struck into an original vein of satirical vernacular poetry, in rattling verses of six, five, and even four syllables, with quick-recurring rhymes, overflowing with grotesque words and images and unrestrained jocularity, and lightened up by bright gleams of fancy. His bent leaned strongly towards satire, and in this kind his chief productions were *The Bowge of Courte*, *Colyn Cloute*, and *Why come ye nat to Courte*. Of these the first is an allegorical poem showing striking power of characterisation; the second, a vigorous and unsparing attack on the corruptions of the church, of which he himself says, 'though my ryme be ragged, tattered and jagged, rudely rain-beaten, rust and moth-eaten, if ye take well therewith, it hath in it some pyth;' the last is a sustained invective against Cardinal Wolsey. He attacks with the most plain-spoken boldness his arrogance, avarice, and incontinence, and does not spare even his 'gresy genealogy' and the 'bocher's stall.' Wolsey felt the sting, and tried to arrest his libeller, but Skelton fled to the sanctuary in Westminster, where Abbot Islip sheltered him till his death, June 21, 1529. Of his other poems the chief are *Phyllyp Sparowe*, a young girl's lament for a pet bird killed in a convent of black nuns at Carowe near Norwich, a masterpiece of delicate and graceful fancy, which Coleridge called 'an exquisite and original poem;' *The Tunnyng of Elynour Rummyng*, a vigorous burlesque picture of low life, its heroine an ale-wife at Leatherhead in Surrey; the *Garlande of Laurell*, a long but less successful poem; and *Magnyfycence*, the only one of his Interludes that has survived. Skelton's reputation for wit, if not ribaldry, was so great that a wretched book of 'merye tales' was popularly linked with his name: as undeserved is Pope's phrase—'beastly Skelton'—written on occasion of a reprint in 1736 of the first collected edition (1568). The only good edition is that by the Rev. A. Dyce (2 vols. 1843).

Skene, WILLIAM FORBES, an erudite Scottish historian, was born at Inverie in Kincardineshire, June 7, 1809, the second son of Scott's friend, James Skene (1775–1861). He had his education at Edinburgh High School, in Germany, and at the universities of St Andrews and Edinburgh, afterwards, in 1831, becoming a Writer to the Signet in Edinburgh. In 1879 he received the D.C.L. degree from Oxford, and in 1881 he succeeded Hill Burton as Historiographer for Scotland. Among the works of this great constructive archæologist and historian are *The Highlanders of Scotland* (2 vols. 1837), *The Dean of Lismore's Book: a Selection of Ancient Gaelic Poetry* (1861); *Chronicles of the Picts and Scots* (1867); Fordun's *Cronica Gentis Scotorum* (2 vols. 1871); *The Four Ancient Books of Wales* (2 vols. 1868); *Celtic Scotland, a History of Ancient Alban* (3 vols. 1876–80); and *Memorials of the Family of Skene of Skene* (New Spalding Club, 1887).

Skepticism. See SCEPTICISM.

Skerries, a name applied to several groups of isolated rocky islets round the coasts of Great Britain, more especially a group about 2 miles off the north-west coast of Anglesey, having a lighthouse 117 feet high. See also PENTLAND FIRTH.

Skerries, an Irish seaport, 18 miles N. by E. of Dublin. Pop. 2227.

Skerryvore, the chief rock of a reef which lies 10 miles SW. of Tyree and 24 W. of Iona. This reef, which stretches 8 miles west-south-westward, is composed of compact gneiss, worn smooth by the constant action of the waves, and was long a terror to mariners, having caused the loss of one ship annually for forty years previous to 1844. The Northern Lighthouse Commission had long intended the erection of a lighthouse on Skerryvore, the only point of this dangerous reef which could afford the needful foundation; but the difficulty of landing on the rock, from the immense force (3 tons to the superficial foot) with which the Atlantic waves beat upon it, caused the delay of the scheme till 1838. The design and superintendence of the building were entrusted to Alan Stevenson, who followed generally the mode adopted by his father, Robert Stevenson, in the construction of the Bell Rock Lighthouse, and completed his work in 1844. The lighthouse is 138½ feet high; at the base 42, and at the top 16 feet in diameter. The light, a revolving one, can be seen at a distance of 18½ nautical miles. The cost of erection was £86,977. See A. Stevenson's *Account of the Skerryvore Lighthouse* (Edin. 1848).

Skibbereen, a market-town of the county of Cork, Ireland, 54 miles SW. of Cork, at the terminus of a branch-line, with a little trade in agricultural produce. It suffered terribly during the famine of 1846-47. Pop. 3631.

Skiddaw, a mountain (3054 ft.) of Cumberland, flanking the east side of Bassenthwaite Water, and 5½ miles NNW. of Derwentwater and Keswick.

Skimmer, or SCISSORS-BILL (*Rhynchops*), a genus of long-winged sea-birds belonging to the Gull family (*Laridæ*). Their most distinctive feature is the long, thin bill with the lower half longer than the upper. There are only three known species, occurring respectively in Asia, Africa, and America. Darwin describes the American skimmers, or, as they are also called, Shearwaters (*R. niger*), as skimming along the surface of the water, generally in small flocks, ploughing up small fish with their projecting lower mandible, and securing them with the upper half of their scissors-like bills. See GULL.

Skin. The skin forms a complete covering for the outer surface of the body, and consists of two distinct layers, of which the outer is termed the *epidermis*, *cuticle*, or *scarf-skin*, and the inner the *corium* or *cutis vera*. Moreover, the skin contains certain structures termed 'tactile corpuscles,' by means of which the properties of bodies are revealed to the sense of touch; and associated with the skin there are such accessory organs as hair, nails, sebaceous glands, and sweat-glands.

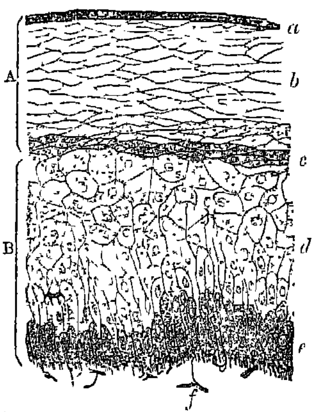

Fig. 1.—Section of Epidermis from the Human Hand, highly magnified (Ranvier):

A, horny layer, consisting of *a*, superficial horny scales; *b*, swollen out horny cells; *c*, stratum lucidum: B, rete mucosum, consisting of *d*, prickle cells; *e*, elongated cells near corium; *f*, a nerve-fibre.

The *epidermis* is non-vascular, and forms a protective covering for the cutis vera. It varies in thickness from $\frac{1}{240}$th to $\frac{1}{24}$th of an inch, being thickest in the palms of the hands and soles of the feet. In structure it consists of cells, closely adherent to each other by their margins, and arranged in many irregular layers. The individual cells vary in shape, being perpendicular in the deepest layer, and passing by various transitions into a surface stratum of hardened flattened cells, which are constantly being thrown off by desquamation; fig. 1 shows the various transitions. In many of the cells, even of white races, pigment granules are found, and these account for the tawny colour of the skin. A section of the epidermis of a Negro's leg, showing the cells of the horny and mucous layers, will be found at Epidermis (q.v.). If a large portion of the epidermis be removed, the process of repair is slow, and proceeds from the edges of the wound, but recovery is quicker if any of the deeper cells of the layer remain. Skin-grafting aims at transplanting small portions of healthy epidermis—including its deeper layers—to denuded surfaces, and when the grafts take root the raw surface is much more speedily covered because the healing process spreads from each graft (see RHINOPLASTIC OPERATIONS). Nails and Hair (q.v.) are growths of the epidermis.

The *cutis vera*, *corium*, or *true skin* is a vascular and sensitive structure, everywhere covered by the epidermis. It rests on a layer which in most places contains fat—the *panniculus adiposus*—and to this layer the corium is sometimes loosely, sometimes firmly, attached. In structure the true skin consists of an interlacing network of white fibrous tissue with a mixture of elastic fibres. On its deep aspect the meshes are more open, and contain lumps of fat. In this way the corium gradually blends with the subcutaneous layer, and so its thickness is not definite, but is generally regarded as varying from $\frac{1}{70}$th to $\frac{1}{8}$th of an inch. Wherever hairs occur bundles of muscular fibres are found. The outer surface of the corium is characterised by furrows, which also affect the epidermis. The largest furrows are found opposite the flexures of joints. Finer furrows may be seen on the backs of the hands; while on the skin of the palms and soles ridges with intervening furrows form patterns which are characteristic of each individual. These patterns are permanent, and do not materially change from infancy to adult life (Galton). The latter furrows are due to the fact that the outer surface of the corium is beset with small elevations termed *papillæ* (fig. 2). These are most fully developed where touch is finest, and they fit into corresponding depressions on the under surface of the epidermis. The deeper layers of the corium are plentifully supplied with blood-vessels, which form a fine network of capillaries from which loops pass into most of the papillæ. Fine nerves are also supplied to the corium for distribution to the 'touch corpuscles' found in certain papillæ. As a rule papillæ with touch corpuscles have no capillary loop, and thus we distinguish 'vascular' and 'tactile' papillæ. The hair-follicles also receive nerves, and fine varicose nerve-fibrils pass into the deeper layers of the epidermis. *Sebaceous glands*, found wherever hairs are present, pour their secretion into hair-follicles at a short distance from the mouth, unless the hair be small, when the gland may open on the surface of the skin, and the hair project through its duct. Being outgrowths of the hair-follicles they are accessory structures to the epidermis, although the body of the gland is lodged in the corium. They are specially abundant in the scalp and face—some of the largest being found on the side of the nose. Their secretion consists of the fattily degenerated and disintegrated cells which line their interior (see ACNE).

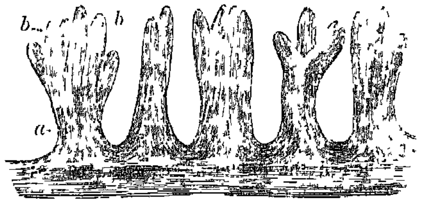

Fig 2.—Compound Papillæ of Surface of Hand:

a, base of a papilla, *b*, *b*, their separate processes. Magnified 60 diameters.

Sweat-glands are found at various depths beneath the corium. Each gland is a coiled-up tube, of which the *duct* is that part leading in a corkscrew manner through the corium and epidermis to the surface. These glands are also outgrowths of the epidermis, and they are lined by epithelial cells. They are most numerous where there is no hair, but they occur everywhere in connection with the skin. Krause states that 2800 open on a square inch of skin from the palm; half as many on a similar area on the back of the hand; fewer on the surface of the forehead; 1100 on breast and forearm; while from 400 to 600 are found on the square inch of the lower limbs and back of the trunk. The sweat is naturally *alkaline*, although it may be found acid owing to the presence of fatty acids derived from the decomposition of sebum. In prolonged sweating the secretion becomes neutral and again alkaline. It is colourless, of a saltish *taste*, and its odour, which is due to volatile fatty acids, varies with different parts of the body. Coloured sweat is among the phenomena of nervous affections, and instances of blue and bloody sweats are on record. In jaundice the sweat may contain bile-pigment.

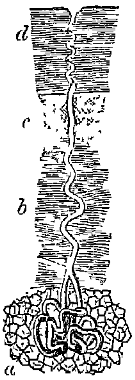

Fig. 3.—Magnified view of a Sweat-gland, with its duct (Wagner):
a, the gland surrounded by fat cells, *bcd*, its duct, passing through corium and epidermis.

Ceruminous glands are found in the auditory passage, and have such a close resemblance to sweat-glands that the former may be regarded as modifications of the latter. They yield an adhesive bitter secretion—the wax—which protects the drum of the ear from insects, dust, &c.

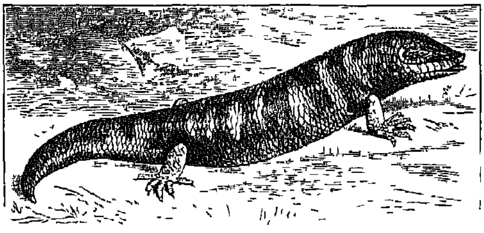
The most important function of the skin, Touch (q.v.), is separately treated. Regarded as a protective covering, the skin possesses the combined advantages of toughness, resistance, flexibility, and elasticity; the connective framework being the part which mainly confers these properties, although the epidermis co-operates with it. The subcutaneous layer of fat, and the modifications of epidermis in various forms, as hairs, wool, feathers, scales, &c., serve for the preservation of warmth, and occasionally (when they occur as claws, talons, &c.) as means of offence or defence. The skin is the seat of a twofold excretion—viz. of that formed by the sudoriparous glands and that formed by the sebaceous glands. The fluid secreted by the sudoriparous glands is usually formed so gradually that the watery portions of it escape by evaporation as soon as it reaches the surface; but in certain conditions, as during strong exercise, or when the external heat is excessive, or in certain diseases, or when the evaporation is prevented by the application of a texture impermeable to air, as, for example, oiled silk, or the material known as mackintosh, or india-rubber cloth, the secretion, instead of evaporating, collects on the skin in the form of drops of fluid. When it is stated that the sweat contains urea, lactates, extractive matters, &c., and that the amount of watery vapour exhaled from the skin is, on an average, 2¼ lb. daily, the importance of the sudoriparous glands as organs of excretion will be at once manifest. Moreover, there is reason to believe, from the experiments of Scharling, Gerlach, and others, that the importance of the skin as a *respiratory* organ is far from inconsiderable, very appreciable quantities of carbonic acid being exhaled hourly by the external surface of the body. In the amphibia, in which the skin is thin and moist, the cutaneous respiration is extremely active; and that the respiratory function of the skin in the higher animals is also considerable is proved not only by measuring the excreted carbonic acid, but by the fact that if the skin is covered by an impermeable varnish, or if the body is enclosed, all but the head, in a caoutchouc dress, animals soon die, as if asphyxiated, their heart and lungs being gorged with blood, and their temperature before death gradually falling many degrees.

The skin is, moreover, an organ of absorption: mercurial preparations, when rubbed into the skin, have the same action as when given internally. Thus potassio-tartrate of antimony, rubbed into the skin in the form of ointment or solution, may excite vomiting, or an eruption extending over the whole body. The effect of rubbing is probably to force the particles of the matter into the orifices of the glands, where they are more easily absorbed than they would be through the epidermis. It has been proved by the experiments of Madden, Berthold, and others, that the skin has the power of absorbing water, although to a less extent than occurs in thin-skinned animals, such as frogs and lizards. This fact has a practical application. In severe cases of dysphagia—difficult swallowing—when not even fluids can be taken into the stomach, immersion in a bath of warm water, or of milk and water, may assuage the thirst. Sailors, also, when destitute of fresh water, find their urgent thirst allayed by soaking their clothes in salt water.

The *diseases* of the skin are classified at DISEASES; the more important affections are noticed in special articles. See also ALBINOS, BATH, NERVOUS SYSTEM. The colour of the skin as a means of distinguishing race is dealt with at ETHNOLOGY. Peculiarities in the skins of various animals are treated in the articles on those animals (HIPPOPOTAMUS, RHINOCEROS, &c.). For skins as articles of commerce, see FURS, LEATHER. For the stuffing of animals, see TAXIDERMY.

SKIN-CASTING is a popular term for processes which vary not a little in degree and even in nature. In most cases the outer layer of the epidermis tends to die away, and is separated off either very gradually and in small pieces at a time, or in large shreds, or in a continuous slough (see SNAKES). The moulting of feathers and the casting of hair are analogous. In the moulting or 'ecdysis' of Crustaceans and other Arthropods, what is cast is the cuticle—a product of the underlying epidermis. See CRAB, CRAYFISH, CRUSTACEA.

Skink (*Scincus officinalis*), an African lizard, which lives in sandy places, and burrows with great rapidity. It is from six to eight inches long, generally of a reddish-dun colour, with darker transverse bands, a wedge-shaped head, and four rather strong limbs. For ages it has been in great repute for imaginary medicinal virtues; it was largely imported on this account into ancient Rome, and is still in high esteem in the East, dried skinks finding a ready sale in many places, as Cairo and Alexandria. There is almost no disease for which skink-powder has not been supposed to be a cure. The Skink is typical of the family Scincidæ, of which Eumeces with



Skink (*Scincus officinalis*).

well-developed legs, Seps with very weak legs, Nessia with rudimentary legs, Acontias with no legs are representative genera. In many there are well developed bony scutes beneath the rounded scales. See LIZARDS.

Skinner, JOHN, the author of 'Tullochgorum,' was born in the parish of Birse, Aberdeenshire, 3d October 1721, the son of the schoolmaster there. He graduated at seventeen at Aberdeen, taught in the parish schools at Kemnay and Monymusk (where he left the Presbyterian for the Episcopal Church), and in 1740 went as private tutor to Shetland, where he married the daughter of the Episcopal clergyman. In 1742 he was ordained a deacon, and placed at Longside, where he ministered for sixty-four years. In 1746 his house was pillaged and his chapel burned by the Hanoverian soldiery, although Skinner was no Jacobite, and was one of the few who, so far as he could, complied with the terms of the Toleration Act—for which, however, he had to receive the absolution of his bishop, the church at large regarding compliance as sin. The Act of 1748 he and his people evaded for the most part, and in 1753 he was imprisoned for six months. At some period before 1789 he became dean of the diocese; and he died at Aberdeen, in his son's house, 16th June 1807.

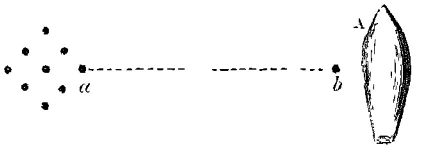
Skinner is remembered only by a few songs. He published *An Ecclesiastical History of Scotland* (2 vols. 1788), and several controversial writings; and other works appeared posthumously, including those wrought out after the theory of John Hutchinson (q.v.). His *Poems* were collected in 1809 (3d ed. 1859), the best being 'The Ewie wi' the Crookit Horn' and 'Tullochgorum'—praised by Burns, in a friendly letter to Skinner (1787), as 'the best Scotch song Scotland ever saw.' See the Life by the Rev. Dr Walker (2d ed. 1883).

His son, JOHN SKINNER, Primus of Scotland, was born at Longside, 17th May 1744, in 1753 shared his father's imprisonment, and graduated at Aberdeen at the age of sixteen. In 1763, when only nineteen—for the same reason as in the case of Dr Chalmers, because he was 'a lad of pregnant parts'—he was ordained and placed in charge of Ellon, with a stipend of £25 a year, eked out by farming. Eleven years later he was called to Aberdeen, where by 1776 his congregation had so increased as to compel his removal to a larger house at Longacre, where the upper floor as usual was fitted up as a 'meeting house'—the large 'upper room' in which Dr Seabury was consecrated in 1784. By this time Skinner had been made coadjutor-bishop (1782), and in 1787 he became bishop of the diocese, and in 1788 primus. The death of Prince Charles Edward, which occurred in this last year, was the solution of the church's Jacobite difficulty; and the leading part in obtaining the Relief Act of 1792 fell to the primus. Skinner proved a wise and successful administrator, and his great influence was exerted invariably for the real good of the church. He died on 13th July 1816, and was succeeded as bishop by his son. See the Life by Dr Walker (1887).

Skipton, a market-town in the West Riding of Yorkshire, is finely situated in the broad and fertile valley of the Aire, 26 miles NW. of Leeds. The capital of Craven, it is a gray-looking place, with manufactures of cotton and woollen goods, and is an important station on the Midland line. The castle, once the chief seat of the Cliffords (q.v.), is of two periods, the reigns of Edward II. and Henry VIII., and is partly a ruin, partly inhabited. The church has some interesting monuments; and there are also a public hall (1861), a grammar-school (1548; rebuilt in 1876-77 at a cost of £12,000), and a saline spring. Bolton Abbey (q.v.) is 6 miles distant. Pop. (1851) 4962; (1891) 10,376. See W. H. Dawson's *History of Skipton* (1882).

Skirret (*Sium Sisarum*), a perennial plant of the natural order Umbelliferæ, a native of China and Japan, but which has long been cultivated in gardens in Europe for the sake of its roots, which are tuberous and clustered, sometimes 6 inches long, and of the thickness of the finger. They are sweet, succulent, and nutritious, with a somewhat aromatic flavour, and when boiled are a very agreeable article of food. A kind of spirituous liquor is sometimes made from them. Good sugar can also be extracted. Skirret was at one time more cultivated in Britain than it is at present, although there seems to be no good reason for its having fallen into disrepute. Worledge called it the 'sweetest, whitest, and most pleasant of roots.' It is propagated either by seed or by very small offsets from the roots. It has a stem of 2 to 3 feet high; the lower leaves pinnate, with oblong serrated leaflets, and a heart-shaped terminal leaf, the upper ones ternate with lanceolate leaflets.

Skittles, a game usually played in a covered shed, called a skittle-alley, about 60 feet in length. The skittles are made of hard wood of the shape shown at A in the fig., and they are placed upon the floor of the shed in the order shown at *a*. The player, standing at *b*, trundles a wooden missile, shaped like a small, flat cheese, from 7 to 14 lb. in weight, and tries to knock down the whole of the skittles in as few throws as possible. The game is very similar to the American bowls, which is played with ten pins arranged in the form of a triangle; and the missile, a round wooden ball, is rolled along a carefully constructed wooden floor. The game of skittles (*Kegel*) with round balls is zealously played in most parts of Germany, but with great local variations. Thus in Silesia there are sometimes fifteen or seventeen pins, though the usual number is nine; and in some places the round balls have holes in them for the fingers of the player—so that they are thrown rather than trundled. Sometimes the pins have different forms and values, one being called the king; and there are many ways of arranging them. The game seems to be of ancient Germanic origin, and to have come from Germany to the Netherlands, England, and France. It is described by Hugo von Trimberg, rector of a monastery at Bamberg in the second half of the 13th century (when there were only three pins). The old English game was called Kails (Sir Philip Sidney has *Keels*; in Scotland *Kyles*—all derived from the German *Kegel*), and was played, not with a ball or disc, but with a short club—according to Strutt, with a 'sheep's leg-bone.' There is a learned monograph on the game by Rothe (Halle, 1879). See also BOWLS.



Skobeleff, MICHAEL DMITRIEVITCH, Russian soldier, born in 1841, entered the Russian guards when twenty, fought through the war of the Polish rising (1863), and in 1866 was called to join the general staff. During the years 1871-75 he was on active duty in Asia, preparing for and then taking part in the conquest of Khiva and conquering Khokand. In the Russo-Turkish war of 1877-78 he bore a conspicuous part: in the stormings of Plevna he commanded the left wing and entered that position at the head of his army corps; and he took prisoners the so-called Shipka army of the Turks and captured Adrianople. In 1880 he was back again in Asia; and it was he who commanded at the storming of the Turkoman stronghold Geok Tepe (24th January 1881). Skobeleff was one of the recognised leaders of the aggressive and militant wing of the Panslavist agitators; but he died suddenly on 7th July 1882, at Moscow, before he could put his ambitious schemes into execution.

See *Personal Reminiscences of General Skobeleff*, by Nemirovitch-Dantchenko (Eng. trans. 1884), and the Life in German by Ossipovitch (Hanover, 1887).

Skoptsy. See RUSSIA, Vol. IX. p. 36.

Skowhegan, a town of Maine, capital of Somerset county, on the Kennebec (which here has a fall of 28 feet), 37 miles by rail NNE. of Augusta. It manufactures flour, oil-cloth, axes, paper, woollens, leather, &c. Pop. 5068.

Skua, or SKUA GULL. See GULL.

Skull. The skull is divided into two parts, the cranium and the face. In human anatomy it is customary to describe the former as consisting of eight and the latter of fourteen bones; the eight cranial bones, which constitute the brain-case, being the *occipital*, two *parietal*, *frontal*, two *temporal*, *sphenoid*, and *ethmoid*: while the fourteen facial bones, which surround the cavities of the mouth and nose and complete the orbits or cavities for the eyes, are the two nasal, two superior maxillary, two lachrymal, two malar, two palate, two inferior turbinated, vomer, and inferior maxillary. The bones of the ear, the teeth, and the Wormian bones are not included in this enumeration. The lower jaw articulates with the temporal bones by means of a diarthrodial Joint (q.v.), but all the others are joined by *sutures*. On the base of the cranium the occipital and sphenoid bones articulate by means of a plate of cartilage (synchondrosis) in young subjects; in adults this becomes bony union. Sutures are named from the bones between which they are found, but to those around the parietal bones special names are given—e.g. inter-parietal or *sagittal*; occipito-parietal or *lambdoid*; fronto-parietal or *coronal*; parieto-temporal or *squamous*. During adult life many of the sutures close by bony union and disappear, but both the age at which this occurs and the order of its occurrence are subject to variation. Wormian bones are irregular ossifications found in relation to the sutures of cranial bones, but seldom seen in relation to the bones of the face. They are most frequent in relation to the lambdoid suture, and seldom one inch in diameter. The closure of a suture stops the growth of the skull along that line, and in order to compensate for this defect an increase of growth may occur at right angles to the closed suture and thus irregularities of form may result: for example, closure of the sagittal suture stops transverse growth, but the skull continues to grow in the longitudinal and vertical directions, with the result that a boat-shaped cranium is produced—scaphocephaly. Irregular forms may be produced artificially by pressure applied early in life. This is best seen among certain American tribes who compress their children's heads by means of boards and bandages. The bones of the skull are pierced by holes (*foramina*), and similar holes are found in relation to the adjacent margins of bones. Most of these foramina are situated in the base or floor of the skull, and are for the ingress of arteries and the exit of veins and cranial nerves. The largest of these foramina —the foramen magnum—is found in the occipital bone. It is situated immediately above the ring of the atlas vertebra, and through it the continuity between the brain and spinal cord is established, and further, it transmits the vertebral arteries which supply blood to the brain. Compared with the skulls of animals, the form of the human skull is modified (1) by the proportionately large size of the brain and the consequent expansion of the bones which surround it; (2) by the smaller size of the face, especially of the jaws, so that the face of man, instead of projecting in front of, is *under* the forepart of the cranium; (3) by the *erect attitude*, which places the base of the skull at a considerable angle with the vertebral column, and, in consequence of a development backwards from its point of articulation with the vertebræ, the skull is nearly balanced on the summit of the vertebral column. Hence the orbits look forwards and the nostrils look downwards The development of the skull is a subject of great interest, not only in itself, but as throwing light on many points which the study of the adult skull would fail to explain. At a very early period of fœtal existence the cerebrum is enclosed in a membranous capsule external to the dura mater, and in close contact with it. This is the first rudiment of the skull, the cerebral portion of which is consequently formed before there is any indication of a facial part. Soon, however, four or five processes jut from it on either side of the mesial line, which grow downwards, incline towards each other, and unite to form a series of inverted arches, from which the face is ultimately developed. Imperfect development or ossification of these rudimentary parts of the face gives rise to 'hare-lip' and 'cleft-palate,' or in very extreme cases to the monstrosity termed 'Cyclopean,' in which, from absence of the frontal processes, the two orbits form a single cavity, and the eyes are more or less blended in the mesial line.

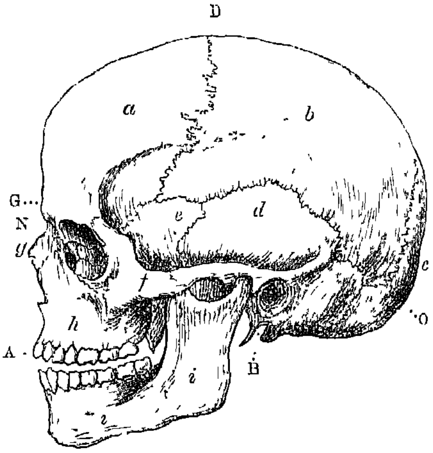


Fig. 1.—Side View of Human Skull:

a, frontal bone; *b*, parietal bone; *c*, occipital bone; *d*, temporal bone (squamous portion); *e*, sphenoid bone; *f*, malar bone; *g*, nasal bone; *h*, superior maxillary or upper jaw bone; *i*, inferior maxillary or lower jaw bone

BD, height of cranium; GO, length of cranium; BN, basinasal length, BA, basialveolar length. (These measurements are supposed to be made in a straight line from point to point)

The cartilage, formed at the base of the membranous capsule, is speedily followed by the deposition of ossific matter at various points of the capsule, which soon becomes converted into flakes of bone; while the intervening portions, which remain membranous, permit the skull to expand as its contents enlarge. Then follows the appearance of osseous nuclei in the cartilage at the base, corresponding to the future occipital and sphenoid bones. Lastly, the various bones, some originating in membrane, and some in cartilage (see OSSIFICATION), approach one another by gradual enlargement, and become united in various ways, so as to form a continuous, and ultimately an unyielding bony case, which is admirably adapted for the defence of the brain, for sheltering the organs of special sense, and for being attached to the ligaments and muscles by which the skull is supported and moved on the spine. At the period of birth most of the principal bones have grown into apposition with their neighbours, forming the sutures; but one large vacuity remains at the meeting-point of the parietal and frontal bones, which is termed the anterior fontanelle (so called from the pulsations of the brain, which may be here seen resembling the rising of water at a spring or fountain. There are two fontanelles in the mesial line (as shown in fig. 2), and two lateral fontanelles on either side (as shown in fig. 3), which do not close till the second year after birth, and sometimes remains open much longer. The deficiency of the osseous brain-case at this position not only facilitates delivery, but also acts to some extent like a safety-valve during the first months of infantile life, at which time the brain bears an unusually large proportion to the rest of the body, and is liable to sudden variations of size from temporary congestion, and other causes. The sutures remain distinct long after the closure of the fontanelles, and serve a purpose both in permitting an increase of the size of the cranium by the growth of the bones at their edges, and in diminishing and dispersing vibrations from blows, and thus contributing to the security of the brain.

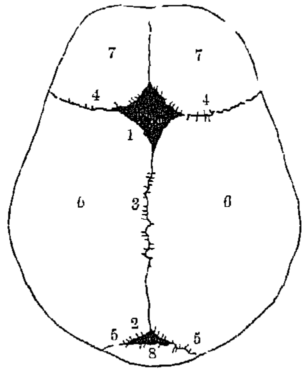

Fig. 2.—Human Skull at Birth, from above:
1, anterior fontanelle; 2, posterior fontanelle; 3, sagittal suture; 4, 4, coronal suture; 5, lambdoid suture; 6, 6, parietal bones, 7, 7, two halves of the frontal bone, still ununited, 8, occipital bone

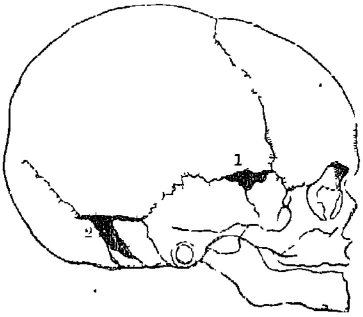

Fig. 3.—Human Skull at Birth (side view): 1, 2, lateral fontanelles.

The number of centres of ossification in the skull is tolerably constant; each bone having a certain number. After the sutures have been formed, and the skull has acquired a certain thickness, a process of resorption commences in the interior of the bones, and reduces the originally dense structure to a more or less cellular or cancellated state. The interior thus altered is called the *Diploë*, and by this change the weight of the skull is much diminished while its strength is scarcely affected. The diploe usually begins to be apparent about the tenth year, and is most developed in those skulls which are thickest. A continuation of the same process of resorption which causes the diploe gives rise to the formation of the cavities known as the frontal and sphenoid sinuses. The formation of the diploe divides the walls of the cranium into three layers—viz. an outer tough layer; an inner dense, brittle, and somewhat glass-like layer, known as the vitreous table or layer; and the intervening cancellous diploe. Diploe is absent from the cribriform plate of the ethmoid bone and from the roof of the orbital cavities, and thus these are the thinnest parts of the cranium. The growth of the skull after the seventh year proceeds slowly, but a slight increase goes on to about the age of twenty. The skull-bones are freely supplied with blood from arteries which pass from the dura mater internally and the pericranium externally, though the numerous foramina observed on both surfaces; the blood being returned by veins which take various directions.

The fact that concussion of the brain scarcely ever proves fatal, unless there is also fracture of the skull, affords the most distinct evidence that the skull is constructed in such a manner that so long as it maintains its integrity it is able to protect its contents from serious lesion. This marvellous protective power is due to its rounded shape, whereby its strength is increased, and in consequence of which blows tend to glide off it without doing material damage. Moreover, the curved lines or ridges which may be traced round the skull tend to strengthen it. The weakest part of the skull is at the base. Hence, notwithstanding its removal from exposure to direct injury and the protection afforded by the soft parts, fracture takes place more frequently at the base than at any other part of the skull, fracture often taking place here even when the skull was not broken at the part struck. There are two points in the architecture of the bones of the face which deserve especial notice—viz. (1) the great strength of the nasal arch; and (2) the immobility of the upper jaw, which is fixed by three buttresses—the nasal, the zygomatic, and the pterygoid.

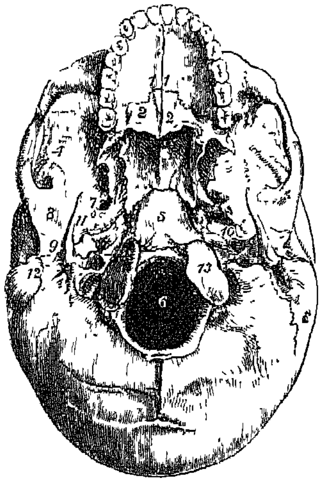

Fig. 4.—Base of the Human Skull:
1, 1, hard palate; 2, 2, palate bones; 3, vomer; 4, zygomatic fossa; 5, basilar process of the occipital bone, 6, foramen magnum; 7, foramen ovale; 8, glenoid fossa; 9, external auditory foramen; 10, carotid foramen of the left side; 11, styloid process; 12, mastoid process; 13, one of the condyles of the occipital bone

The base of the skull, whether seen from within or from below, presents many objects of physiological interest in relation to the nervous system. As seen from within, the base presents on each side three fossæ, corresponding to the anterior and middle lobes of the cerebrum and to the cerebellum. These fossæ are marked, as is the whole skull-cap, by the cerebral convolutions, and they contain numerous 'foramina' and 'fissures' which give passage to various sets of nerves and blood-vessels. The external or outer surface of the base of the skull, if we consider it from before backwards, is formed by the palate processes of the superior maxillary and palate bones; the vomer; the pterygoid and spinous processes of the sphenoid and part of its body; the under surface of the temporal bones; and the occipital bone. The most important of the parts which it presents are named at fig. 4.

The *Morphology of the Skull* is the highest and most difficult problem of comparative anatomy, and has cost the most extraordinary labour for its solution. Goethe and Oken independently suggested that the skull was to be regarded as the modification of a series of four vertebræ, and this 'vertebral theory' was worked out in the most elaborate detail by Owen and other anatomists (see SKELETON). Huxley, however, in a celebrated Croonian Lecture (1858), revised and extended the hitherto neglected embryological observations of Rathke, proposed an unanswerable destructive criticism of the archetypal theory, and may be said to have thus definitely placed the newer view in the way of general acceptance. An enormous amount of detailed research, for which we are indebted chiefly to Parker in England and Gegenbaur in Germany, has established the newer theory on the sure ground of actual observation.

Taking first the simple unsegmented cartilaginous cranium of a skate or dog-fish, with its appended jaws and branchial arches, we find that in development, though the notochord extends into the region of the head, the vertebræ stop altogether short of it; but that on each side of the cranium there arise a pair of cartilaginous bars—the *trabeculæ* or 'rafters' of the future skull—and three pairs of cartilaginous capsules, nasal, ocular, and auditory, form round the developing sense-organs; the nasal capsules immediately unite with the ends of the trabeculæ, which are meanwhile uniting below, and growing up at the sides to form the brain-case. The auditory capsules become united with the trabeculæ by the appearance of two new masses of cartilage—the parachordals—the eyes of course remaining free. At first there are no jaws, but a series of seven or more similar vertical cartilaginous bars or arches, considerably resembling the trabeculæ, between which slits open into the pharyngeal cavity. The first pair of these arches develops an ascending process, which passes above the developing mouth, and becomes the 'palato-pterygoid' arch or upper jaw, the original portion remaining as the mandible. The second pair of arches—the 'hyoid'—becomes more or less modified usually to aid in supporting the jaws and floor of the mouth, while the remaining pairs become little modified, and serve throughout life to support the gills.

The more complex bony skulls of higher vertebrates are now in principle readily understood. The chondro-cranium and subjacent arches in all cases develop in the same way, although reduction and even atrophy of the gill arches subsequently takes place. The bones, although similar in the adult, originate in two utterly distinct ways, either by actual ossifications in the substance of the chondro-cranium and jaws, or by the ossification of overlying dermis, and are hence known as cartilage bones and membrane bones respectively—the latter corresponding to the dermal bones and teeth of ganoid and elasmobranch fishes. In mammals a further extraordinary specialisation takes place: the ends of the mandibular and hyoid arches lose their suspensory function, are taken up during development into the interior of the ear capsule, and are metamorphosed into the auditory ossicles.

Various Forms of the Skull.—Age.—At birth the existence of the fontanelles has already been referred to. The frontal and parietal eminences are especially prominent, and the mastoid process is absent. The face is only one-eighth of the bulk of the cranium, whereas in the adult the face is equal to one-half. During the first seven years the skull grows rapidly, and by this time many parts have attained definite size. At the period of puberty the face and regions of the air-sinuses undergo expansion. The face elongates owing to the growth of teeth and the increase in the size of their alveolar sockets. In old age the skull may become lighter and thinner or the reverse. Loss of the teeth and absorption of their sockets result in diminution of the size of the face, and thus the upper jaw recedes, while the chin becomes prominent.

Sex.—It is not always possible to determine the sex from the skull; but, as a rule, the skull of the male has more strongly marked muscular impressions, while the mastoid processes, superciliary ridges, and air-sinuses are more pronounced than in the female, whose skull generally retains the leading features of a young skull.

Race.—In comparing the skulls of different races of mankind it is necessary to have recourse to various methods of measurement, and these are usually conducted on the skulls of adult males. The following is a short summary of these methods. (*a*) *Cranial Capacity.*—This is obtained by filling the cranial cavity with shot, and then measuring the quantity in a graduated vessel, special precautions being observed in order to obtain equable results. The capacity of normal human crania varies from 60 to 110 cubic inches—the average in all races being 85 cubic inches—e.g. Eskimo, 91·5; European, 90·3; Chinese and Mongols, 87·3; African Negroes, 82·4; Native Australians (aboriginal), 79·3; Andaman Islanders, 78·1. (*b*) Linear measurement of the *horizontal circumference* of the cranium. In the adult European male the average is 20·7 inches, and in the female 19·6 inches. (*c*) A third method is by comparison of the relative *length*, *breadth*, and *height* of the cranium. The standard of maximum length is taken as 100, and thus $\frac{100 \times \text{breadth}}{\text{length}}$ = *index of breadth* or *cephalic index*; and on this basis skulls are classified in three groups—viz.:

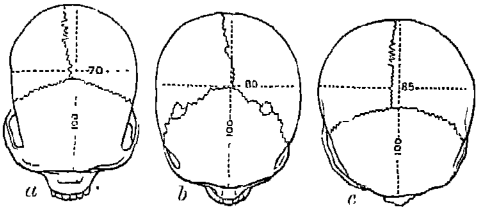

Fig. 5.—Typical Crania seen from the Vertex: *a*, Negro, index 70, Dolichocephalic; *b*, European, index 80, Mesaticephalic; *c*, Samoyed, index 85, Brachycephalic. (After Tylor.)

Brachycephalic = breadth-index above 80.
Mesaticephalic = " " from 75 to 80.
Dolichocephalic = " " below 75.

In a similar way the proportion of height to length may be calculated, and a *height-index* established. It varies less than the breadth-index—e.g.:

	Breadth	Height.
Mongolians of Siberia and Central Asia	88	73
Andaman Islanders	82	77
Chinese	79	75
English	76	71
Native Australians (aboriginal)	71	71
Fiji Islanders	66	74

(*d*) *The Degree of Projection of the Jaws.*—We have seen that the human skull, when compared with the skulls of lower animals, presents a small face extended vertically, and thus placed under the anterior part of the cranial box. Prominent jaws therefore indicate an approach to an animal type, especially when associated with a receding forehead. The degree of projection is expressed by the *gnathic index* of Flower, and is obtained by comparing the basi-alveolar length with the basi-nasal length. When the gnathic index is below 98, skulls are said to be *orthognathous;* from 98 to 103, *mesognathous;* above 103, *prognathous*—e.g. :

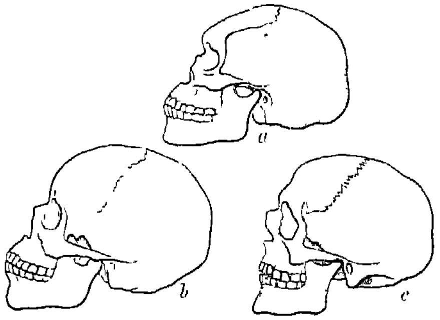

Fig. 6.—Lateral View of three typical Skulls:
a, Australian, prognathous; *b*, African, mesognathous; *c*, European, orthognathous. (After Tylor.)

	Gnathic Index.
English	96
Chinese	99
Eskimo	101
Fiji Islanders	103
Native Australians (aboriginal)	104

(*e*) The form of *the nasal skeleton* and its *anterior openings* is also subject to variation, and so its height and width may be measured, and the relation between the two expressed as a *nasal index.*

Nasal index below 48 = leptorhine.
" from 48 to 53 = mesorhine.
" above 53 = platyrhine.

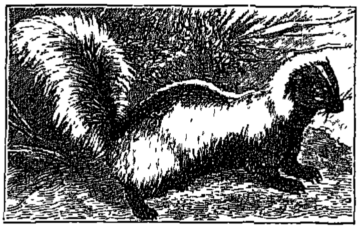
For example:

	Nasal Index.
Eskimo	44
English	46
Chinese	50
Native Australians (aboriginal)	57

In a similar way the form of the orbit is subject to variation, but this is of less consequence than the nose. Other measurements of the face skeleton are also made. A time-honoured measurement, long thought to be sufficient in itself for founding a classification of races, was the *Facial Angle* of the Dutch anatomist Peter Camper (q.v., 1722-89). This was obtained by drawing one line from the centre of the forehead to the most projecting part of the upper jaw just above the incisor teeth, and another from the opening of the ear to the base of the nasal opening; between these was contained the facial angle.

For the illustrative tables in this article we are indebted to the summary in Quain's *Anatomy* (10th ed.).

Skunk (*Mephitis*), a genus of small carnivorous quadrupeds of the family Mustelidæ. The body is elongated, and usually much arched; the tail long, and thickly covered with long, fine hair; the head small, with thick, blunt snout; the legs short, and the paws comparatively large, with five incompletely divided toes. The general colour is black and white. The power, characteristic in some degree of all the Mustelidæ, of forcibly discharging the fetid secretion of the Anal Glands (q.v.) is in the skunks enormously developed. All the species are American, and, as they differ little in habit, the Common Skunk (*M. mephitica*) may be taken as typical of the whole genus. The common skunk—an animal about the size of a cat—has fur of a glossy black; on the forehead is a patch of white diverging into two lines which extend the whole length of the back and meet again in the beautiful bushy tail. The under surface of the tail is also white, and, as it is usually carried erect or laid over against the body, the white is regarded by some naturalists as a 'warning colour.' Thus Mr Belt writes: 'The skunk goes leisurely along, holding up his white tail as a danger-flag for none to come within range of its nauseous artillery.' The common skunk is found throughout North America, but is most abundant in the Hudson Bay region. It chiefly frequents high-lying, bushy, or even rocky districts and the banks of rivers, remaining concealed in its burrow by day, but emerging at dusk in search of the worms, insects, birds, and small mammals which form its food. Its movements are slow and leisurely. It never attempts to run away if pursued, for, feeble and defenceless as it looks, it is most efficiently protected by the possession of a nauseous fluid, the discharge of which neither man nor beast will wittingly provoke. Should an unwary intruder venture too near, the skunk turns its back, erects its tail, and, by means of a muscular contraction, ejects the contents of its anal pouches with a force which carries them to a distance of from 8 to 10 feet. So penetrating is the evil odour of this fluid that it is perceptible a mile off, and has been known to cause nausea in persons within a house with closed doors from which the animal was a hundred yards distant; and so persistent is it that clothes defiled by it can only be purified by prolonged hanging in smoke. It is said that the fluid has irritating properties which excite severe inflammation of the eyes, and cases are cited of Indians who have thus lost their eyesight. The skunk is hunted for its fur, which is in considerable demand; but the hunter must be careful to avoid alarming the animal, and thus causing it to discharge its obnoxious fluid. Skunks usually raise from six to ten young in a season. If taken young they are easily tamed and make pretty pets, for they are cleanly in habit and rarely emit their offensive secretion save when provoked. The Long-tailed Skunk (*M. macrura*) is found in central and south Mexico, and a much smaller species (*M. putorius*), with four white stripes, ranges from the southern states to Yucatan and Guatemala.



Common Skunk (*Mephitis mephitica*).

Skupsh'tina (often spelt *Skuptchina*), the national assembly of the Servians. See SERVIA.

Sky. See ATMOSPHERE, CLOUDS, DUST, and METEOROLOGY.

Skye, an island of Inverness-shire, the second largest of the Hebrides, is separated from the mainland by a channel ⅓ mile wide at the narrowest, Kyle Rhea. Its extreme length, south-south-eastward, is 49 miles; and its breadth varies from 7 to 25 miles; but on account of the extraordinary number of inlets at all parts of the island no point is above 4 miles from the sea. Area, 643 sq. m.; pop. (1841) 23,082; (1861) 18,908; (1881) 16,889; (1891) 15,500. Skye is for the most part mountainous and moory, but it contains some pleasant tracts of arable and pasture land, and one considerable plain, formerly the bed of a lake, in the parish of Kilmuir, where some ruins of a religious house called after St Columba were found. The rocks are mainly volcanic of Tertiary age; and the principal mountains are the Coolin Hills (not Cuchullin), which stretch irregularly from south-west to north-east, terminating in the sharp peak of Sgurr-nan-Gillean (3167 feet) above Sligachan. Another peak, Sgurr Dearg, has been found to be the highest of the range (3234 feet), but Sgurr-nan Gillean will still be regarded as the chief of the Coolin Hills. The serrated outline of these hills arrests the eye at a great distance, and forms the dominant feature in the view at almost every point round the island, and far out at sea. The most famous scene in this region is Coruisk (1⅓ × ¼ mile), the 'stern, dread lake' of Scott's *Lord of the Isles*. Glen Sligachan, ascending 5½ miles from the head of Loch Sligachan, is by many considered the grandest glen in the Highlands. The fantastic Quiraing (1779 feet) and the Storr (2360), in the north of the island, offer splendid scenery, as also do many points along the coast—here columnar basalt formations on a grand scale, and there cliffs 1000 feet high, over which leap many waterfalls, and whose bases are frequently worn into deep caves, some of them of historical interest. One, near Portree, afforded a refuge to Prince Charles Edward; another, on the west coast, was the temporary prison of Lady Grange. The largest arms of the sea are Lochs Bracadale, Dunvegan, and Snizort.

The coasts abound in fish, the most important being herring, salmon, cod, and ling, besides oysters are found in several places. The cod and ling fishery is chiefly confined to Lochs Dunvegan and Snizort. There are no rivers of any magnitude; but salmon and sea-trout are got in some of the principal streams, and trout in most of the fresh-water lochs. Deer are not numerous, nor grouse. West Highland cattle are reared to a considerable extent, but sheep-farming on a large scale predominates. The rainfall averages 65 inches, but the climate is mild and healthy. Agriculture in Skye, being comparatively unprofitable, owing to the moisture of the climate, is falling into entire neglect on some of the chief sheep-farms. The soil, however, is in many places excellent, and capable, in dry seasons, of yielding good cereal crops, while for turnips it is peculiarly suited.

The inhabitants are for the most part poor and ill-housed, but well-behaved and intelligent. At one time they contributed largely to the British army—not less than 10,000 private soldiers, it has been calculated, during the long war with France. The number of soldiers now sent from Skye is very small. In the districts where the men practise fishing nearly the whole of the adult males go to the east coast fisheries in summer, while from all parts of the island young men and women go to the south in search of field-labour. Potatoes and fish are the general diet, meat being a rare luxury. The population is chiefly Celtic, with, however, a considerable Norse admixture. Gaelic is still universally spoken, but is gradually giving place to English. The chief proprietors are still, as of old, Lord Macdonald, whose seat, Armadale Castle in Sleat, is one of the most beautiful in all its surroundings to be seen on the Scottish coasts, and MacLeod of MacLeod, in whose ancient castle of Dunvegan, perched on a headland, Dr Johnson 'tasted lotus' (1773) and Scott slept in the 'Fairy Room' (1814). The principal port of Skye is Portree, a picturesquely situated village of 750 inhabitants, to which steamers regularly ply from Glasgow, and also from Strome Ferry, in connection with the Skye Railway thence to Inverness. Other villages, also calling-points of the steamers, are Kyleakin ('Hakon's strait'), Broadford, and Dunvegan. The celebrated whisky generally known as 'Talisker' is made at the distillery of Carabost, at the head of Loch Bracadale. The inhabitants are nearly all Presbyterians, and chiefly adherents of the Free Church.

See Alexander Smith's *Summer in Skye* (1865), and Robert Buchanan's *Hebrid Isles* (1883).

Skye Terrier, a breed of dogs supposed to be the outcome of a cross between the native dog of Skye and a Maltese terrier, landed from a passing ship—a statement difficult to believe and impossible to prove. Though long known in Scotland, where he was in some places used as a working terrier, it is only of late years that the Skye terrier has become common over the whole of England. The chief beauty of the Skye is its long and graceful coat, which requires so much attention that it is better suited for a town life than a country one. In its proper place, the Skye is a bright and cheerful companion. The modern Skye should be very low at the shoulder, not above 9 or 10 inches high, with as long a body as possible; many good specimens measure 40 inches from nose to tip of tail. The coat should be very long and abundant, nearly touching the ground, but hanging quite straight, without any curl. Colour varies from a dark blue to a light gray. The weight should be about 20 lb. The Skye terrier is divided into two varieties, Prick-eared and Drop-eared. Though many admirers claim working properties for the Skye, as now bred, it should only be regarded as an ornamental dog. The Paisley or Clydesdale terrier, a variety of terrier brought into notice within the last few years, is a Skye with a light-coloured and silky coat, and is kept entirely as a house-dog.

Skye Terrier.

Skyros, or SCYRO, an island of the Grecian Archipelago, the largest of the northern Sporades, 24 miles NE. of Eubœa. Length, 17 miles; area, 79 sq. m. Skyros is very mountainous in the south, the mountains being covered with forests of oaks, firs, and beeches; but the northern part, though also hilly, has several fertile plains, which produce fine wheat and grapes for wine. The only town is Skyro, or St George, on the east coast. This island is associated with the legends of Achilles and Theseus. In 469 B.C. Cimon the Athenian conquered it and carried off to his native city the bones of the hero Theseus. It was likewise celebrated for its goats and its variegated marble. Pop. 3250.

Slade, Felix (1789–1868), of Halsteads, Yorkshire, was an antiquary and art collector, and bequeathed to the British Museum his valuable collections of engravings and of Venetian glass. He also left by will money to found art professorships at Oxford, Cambridge, and at University College, London. Amongst Slade professors have been Ruskin, Sidney Colvin, and W. B. Richmond.

Slags, sometimes called Scoriæ, are fused compounds of silica with lime, alumina, and other substances. Blast-furnace slag is usually little else than a silicate of lime and alumina. In smelting processes the slag floats on the top of the molten metal, and is run off or raked off as 'waste material,' provided that the metal has been practically all extracted from it. Many slags which were thrown away in early times have been profitably smelted again in modern days, owing to the amount of metal left in them. Some slags form an opaque glass, but other varieties are more stone-like in appearance, while some are beautifully crystallised. In Great Britain about 18,000,000 tons of iron blast-furnace slag are annually produced. Until comparatively recent times this was considered useless material, but it is now utilised in several ways. By the action of steam upon it in the melted state it is made into fine threads or filaments called 'slag wool' or 'silicate cotton.' This is a bad conductor of heat and sound, and is used as a covering to boilers, and to prevent sound passing through floors. It is also employed for fireproof netting. In some cases blast-furnace slag has been made into serviceable bricks and large blocks for building, as well as into paving setts. On the Continent a useful building cement, or substitute for mortar, has been made from it. The slag from the manufacture of steel from Cleveland pig-iron by the basic process contains about 17 per cent. of phosphoric acid, and forms a valuable fertiliser for sour, peaty, and clay soils.

Slander is an injury to a person's character and reputation caused by spoken words. It is to be noticed that oral unlike written defamation is only actionable (1) on proof of actual, or, as it is technically termed, special damage; (2) in the following specific cases: (*a*) statement that the plaintiff has committed a criminal offence, (*b*) an assertion that he is suffering from an unclean and contagious disease, (*c*) defamatory words spoken in the way of his business or profession. To impute unchastity to a woman was not in itself actionable unless (it is said) the words were spoken in London, when by the custom of the city an action would lie thereon; but the Slander of Women Act (1891) makes the mere imputation a ground of procedure. The remedy for slander is an action at law for damages. To prove the truth of the alleged slander is a complete answer, and the defence of privilege may also be set up. The criminal law affords no protection against slander, nor will any 'indictment lie for mere words not reduced into writing, unless they be seditious, blasphemous, grossly immoral, or uttered to a magistrate in the execution of his office, or uttered as a challenge to fight a duel, or with an intention to provoke the other party to send a challenge.' This radical distinction between written and spoken defamation is not recognised in Scots law. See Libel.

Slang, a term in regard to the usual meaning of which the best authorities differ widely. It is defined by Webster as 'low, vulgar, unauthorised language;' by Skeat as 'low, vulgar language or a colloquial and familiar mode of expression;' by the *Globe Encyclopædia* as 'the secret jargon of thieves and vagabonds, otherwise known as Cant or Flash;' and by Wedgwood as 'to give bad words, to make insulting allusions.' But any large collection of words universally recognised as *slang* embraces not only vulgar, abusive, familiar, and classically unrecognised terms, as well as those of peculiar jargons or dialects, such as Gypsy, Canting or Flash, Back-slang, and Shelta or Tinkers' Talk, but also a vast number characteristic of trades, pursuits, and positions in every class of society; so that we may agree with Professor A. Barrère, that perhaps the best general definition at which one can arrive is that 'Slang is a conventional tongue with many dialects, which are, as a rule, unintelligible to outsiders.' This confusion of definitions appears to be due to the fact that the word is derived from two sources, each with a separate meaning. According to the generally received popular tradition, which is supported by the Gypsies themselves, and recognised as such by J. C. Hotten (*Slang Dictionary*, 1885), *Slang* is a Romany or Gypsy word. It was originally applied to everything relating to theatres or shows—in Hindustani *Swangi*, also, often, *slangi*. The peculiar jargon or tongue spoken among such show-people, also stage or theatrical language itself, doubtless gave rise to 'slang.' It is also applied as a means of expression by these people to 'licenses to exhibit,' while *to be 'on the slang'* signifies in circus-dialect to be in any way connected with 'the profession.' Slang in this sense means therefore a peculiar or secret language. But as a term of abuse, as in 'slanging' or 'slang-whanging' a man, Skeat properly derives it from the Norwegian *sleng*, a 'slinging or throwing;' hence *slengja kjeften*, 'to sling the jaw;' *slengjeord*, a 'slang or abusive word.' Thieves' slang, or a jargon deliberately intended to protect criminals, is known in India as *bhat*, hence the Gypsy *pat*, or *patter*, erroneously derived by mere conjecture from *paternoster*. In its extended sense it is difficult to draw the line between technical terms—*as for instance those used on the turf or* in sport—and *slang*, especially when equivalents for them are wanting in correct English. Any kind of shibboleth used to distinguish a class, be it of students, clergymen, authors, or the most fashionable circles, is correctly called *slang*, and is recognised as such in the best and last works on the subject.

Copyright 1892 in U.S. by J. B. Lippincott Company.

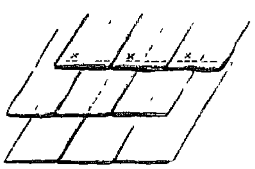
The chief elements of all slang consist first of absolutely foreign words, including those manufactured; as when a costermonger says 'molty kerteever,' from the Ital. *molto cattivo*, for 'very bad,' or a street-vagabond uses the Romany *lelled* ('taken'), for 'arrested.' The other is the substitution of English words for equivalents, as when we hear 'brass' for impudence, 'timbers' and 'pins' for legs, 'claret' for blood, and 'tile' for a hat. Thus it is often in a rough form simile or poetry; 'brass' being indeed of classical origin as applied to the hardness which defies attack. 'A certain proportion of slang words after performing, as it were, quarantine, receive a clean bill of health, and are admitted to that great port the dictionary.' Some even make a reappearance in good language. Thus *humbug*, which meant originally a night-terror or delusion (*Hum*, '*tenebræ*,' Icelandic, and *Bug*, 'a being which terrifies'), was long treated as pure slang, but is now generally used even by the most correct writers in its new meaning. Very little slang in the vulgar or common sense is to be found in Greek or Latin (though Aristophanes and Martial often approach it), or in any European language until the middle ages. François Villon (15th century) wrote ballads in an *argôt* which was by far the most copious and perfected in Europe; a century later Martin Luther compiled a dictionary of *Rotwalsch* (*wälsch*, 'foreign' or 'Italian;' *rot* being either from *roth*, 'red,' or *rotte*, 'a gang'), used by the thieves of his time, in which half the words are Hebrew, derived from the receivers of stolen goods and their *Yiddish* dialect. In Italy there was at the same time a *lingua furbesche*, of which a vocabulary has been published; and in Spain the *Tunanestesca* which was largely mixed with Spanish Gypsy, itself a very much corrupted Romany. English Canting, or the language of the dangerous and vagabond classes, which in a great measure preceded all other forms of slang, did not before the end of the 15th century embrace more than 150 or 200 words. But as C. J. R. Turner has suggested, it was the arrival of the Gypsies in England about 1505, speaking by themselves a perfect language, which stimulated the English nomads to improve their own scanty jargon. According to Samuel Rowlande (1610), a man named Cock Lorell, who was the head of all the strollers or thieves in England, observing that the Gypsies were a strong race, proposed union with them, the result being a congress, 'at which a language, or rather slanguage, was deliberately constructed and adopted' (Leland). 'First of all they think it fit to deuise a certaine kinde of Language to the End that their cousenings, knaueries, and villainies might not be so easily perceiued' (Rowlande). The Gypsies, true to their nature, cheated the English vagabonds by teaching them very little of their own Indian tongue. Harman, a magistrate who in 1567 first published a vocabulary of Slang or Canting, declares explicitly that it was only within thirty years of his time of writing that the dangerous classes had begun in England to use a separate language at all.

The Gypsy language, or Romany, has been greatly misunderstood. It is really an Indian tongue, a dialect of Urdu, or Hindustani, but very ancient. A number of writers, such as Grose, the author of the Life of B. M. Carew, and others, have, misled by Rowlande, published vocabularies of canting as 'Gypsy.' Romany is, however, the corner-stone of English slang. It has constantly contributed new words to the latter—e.g. *tanner*, 'a sixpence,' not from *tāno*, 'small,' as Borrow declares, but from the Hindu *taino*, 'a coin;' and *bosh*, 'mere noise, nonsense.' A second element is the Celtic, which has come chiefly not so much from any of the leading dialects, such as Irish, Gaelic, or Welsh, as from *Shelta*, a language first discovered by the present writer in 1876, and which has since been identified by Kuno Meyer and Sampson with the artificial—or lost—language of the Irish bards. It is still generally spoken by tinkers, and is common even in London. From it we have *mizzle*, meaning 'to go,' or 'to rain' (*mislain*). The writer once met in the street in London two small English boys, who spoke fluently both Romany and Shelta. Shakespeare, it should be noted, makes Prince Hal speak of a tinker's language. *Yiddish* (Ger. *Jüdisch*, 'Jewish') is a strange compound of very corrupt Hebrew and ancient or provincial German, spoken by the commoner Jews. About a century ago a few words from it, such as *toff*, 'good,' began to creep into our slang. It is extensively spoken in the East End of London, and is constantly contributing new words to our popular phraseology. It is in Germany a language of some importance, as the 'Yiddish Chrestomathy' (Leip. 1882) of Max Grünbaum proves, and there are in all about twelve vocabularies of it. There were at one time two newspapers in London alone published in Yiddish. Hotten was the first to show and illustrate the curious fact that among street-musicians and costermongers a very corrupt and singular form of Anglo-Italian had become current. Still more strangely, it has come to be considered by tramps as the lowest and most vulgar means of expression. The keeper of a tramps' lodging-house after hearing a Cambridge professor speak Gypsy and Tinkers' Slang made no remark, but hearing him speak Italian said, 'Well, I'd never a-supposed you 'd been down as low as *that*.' It occasionally happens that a word in the former corresponds exactly to a Gypsy term—e.g. *bosh*, 'a noise,' 'a nonsense,' *pani*, 'water,' *chor*, 'a thief.'

The Dutch language during the time of the Georges contributed a great many words, such as *boefer*, 'a buffer;' *blink*, 'to drink.' In America a still greater number was derived from this source (e.g. sleigh, from *slé*), which have since come over to England. Some confusion has resulted from the fact that owing to its great resemblance to other northern languages philologists have often thought they had discovered in English slang words of Saxon or Danish origin which were really Dutch, and often Dutch slang. There still remains much to be done as regards investigation in this field. About the beginning of the 19th century, when there was much attention paid to such subjects, and many 'fast' or fashionable men affected to be familiar with vulgar life, there sprang up, it is said, about Leadenhall in London, and bearing that name, that which was afterwards known as Back-slang. This consisted of words spelled backwards, such as *top* for pot, *yennep* for penny, *nig* for gin. It has been dying out rapidly of late years, but was at one time extensively spoken in *Nodnol* or London. Many traces of it are to be found in the gay novels and memoirs of the 'Thirties' and 'Forties.' Contemporary with it as regards time of origin is rhyming slang—i.e. the employment of a word which loses its own signification, taking that of another with which it rhymes. Thus *Lord John Russell* means *bustle*, a canting term meaning to pick pockets, also money. Romany or Gypsy, Shelta or Tinkers' Talk, Canting or Kennick, also known at one time as Flash or Thieves' Latin, and confused even by a modern Oxford professor with Gypsy, form the principal English slangs. All have their dialects or local differences. Thus, the Shelta heard in tramps' London lodging-houses is a very much corrupted form of that which is spoken in Scotland. Slang may consist of mere intonation or pronunciation: thus, Hotten gives the use of 'Gawd,' or 'Gorde,' for God, and similar errors by certain clergymen as pulpit slang. There are in America preachers who carry this to such an extent that they have almost formed a language of their own in this way; and a certain bishop was once declared to be in the habit of saying in the pulpit: 'He that hath *yaws* to *yaw*, let him *yaw*,' while in ordinary life he ejaculated plainly enough: 'He that hath *ears* to *hear*, let him *hear!*' Hotten also declares that the peculiar *mispronunciation* of certain names, especially in good society, such as Cooper for Cowper, Carey for Carew, Chumley for Cholmondeley, Sinjen for Saint John, is an anomaly which must correctly be regarded as fashionable slang. The misuse of certain French terms is also slang, which is, however, returned a hundredfold by the rather recent adoption and abuse of English words by Parisians, who, for example, believing that *five o'clock* means to drink tea, have formed the remarkable slang verb *fiveocloquer*, and even say *Fiveocloquons-nous a quatre heures!* Parliamentary, military, sporting, legal and literary, stage, showmen's, shopkeepers', and stock-exchange slang, and that of different callings or trades are all extremely interesting, since there is not one that has not many very old words, often of Norse or Celtic origin, which have not as yet been much investigated. By far the most prolific source of slang of late years has been the American. This has for a 'stem' obsolete English and provincial terms which have been retained chiefly in New England and the West, and which are really not slang, though so called. To these may be added words of German, Dutch, Canadian, French, Red Indian, Negro, and Spanish origin. But by far the most amusing part of Americanisms are the constantly improvised proverbs, sayings, and quaint allusions, eccentric oaths and condensed anecdotes, which, when thrown off in conversation, soon find their way into a newspaper.

The principal works on this subject are Harman's *Caveat for Common Corsetors, vulgarly called Vagabones* (1566); the *Life of Bamfylde Moore Carew* (no date), containing a vocabulary of Canting, miscalled Gypsy; Grose's *Dictionary of the Vulgar Tongue* (1785); *Bacchus and Venus* (1737), with a canting vocabulary, republished as the *Scoundrels' Dictionary*. (This dictionary is said to have appeared by itself in 1710 as *A Dictionary of the Canting Crew.*) The first work of any value on this subject in which slang was treated in its true sense was the *Slang Dictionary* of John Camden Hotten (1859). Its editor unfortunately had no knowledge of Romany, and the existence of Shelta or Tinkers' talk was not known to him. *A Dictionary of Slang, Jargon, and Cant*, by Professor A. Barrére and Charles Godfrey Leland, contains Americanisms, Gypsy, Shelta, Pidgin English, Anglo-Indian, and other terms, with a history of English Slang (2 vols. Lond. 1885). *Slang and its Analogues, Past and Present*, by John Farmer (Lond. 1890 *et seq.*), contains synonyms in the principal modern languages. American slang: see the article AMERICANISMS; John R. Bartlett, *Dictionary of Americanisms* (New York, 1848, and Cambridge, Mass., 1877); J. S. Farmer, *Americanisms, Old and New* (privately printed; Lond. 1888); *Americana*, by Charles Godfrey Leland. Gypsy: see works of George Borrow, *Lavengro, Romany Rye*, &c., and *Dialect of the English Gypsies*, by Dr Bath Smart and Crofton (1863-88). See also the articles GYPSIES and SHELTA, with works there cited. Anglo-Indian: Sir Henry Yule and A. Brunell, *Glossary of Anglo-Indian Colloquial Words and Phrases* (1886). French Slang: Barrère, *Argot and Slang* (Lond. 1887); and the French works of Larchey (1880), Rigaud (1881), Delvau (1883), and Vitù (1890). German Slang: Avé Lallemant, *Deutsches Gaunerthum* (1862); Genthe, *Deutsches Slang* (1892). Pidgin English: *Pidgin English Ballads*, with vocabulary of the Jargon, by Charles G. Leland (1886).

Slate, or CLAY-SLATE (Fr. *esclat*, a 'shiver' or 'splinter'), is a highly metamorphosed argillaceous rock, fine-grained and fissile, and of a dull blue, gray, purple, or green colour. A red slate is found at Acton, Quebec. Slate splits into thin laminæ or plates, that are altogether independent of the layers of deposit; though sometimes coinciding with them, they more frequently cross them at different angles (see CLEAVAGE). Some rocks that split into the thin plates of the original stratification are popularly but erroneously named slate, as thin bedded sandstones properly called flagstones or tilestones, sometimes used for roofing. True slate is a very compact rock, little liable to be acted upon by atmospheric agencies. It is chiefly obtained from Palæozoic strata, but it is found also among more recent rocks. It is used for various purposes, being split into thin slabs of small size for ordinary roofs and into larger slabs for dairy fittings, wash-tubs, cisterns, tables, &c., and, when polished, for writing-slates and 'blackboards.' School slates are manufactured in very large numbers in Wales. They are split, like roofing slates, by hand; but the sawing, grinding, and polishing processes are done by machinery, the making of the wood frames for them being also done by machines. Recently slate has been used in the United States for coffins, and there and elsewhere it has for some time past been cut into gravestones, for which it is not very suitable. There are extensive quarries of roofing-slate in Wales and Scotland, and in the Ardennes in France, some of which have been wrought for a long time. For some years previous to 1891 the average annual quantity of slates quarried or mined in England and Wales amounted to about 450,000 tons (value one million sterling), Carnarvonshire and Merionethshire furnishing nine-tenths of the whole; and among the great slate-quarries there may be mentioned those of Penrhyn (near Bethesda), Llanberis, and Festiniog. Considerable but much smaller quantities are produced in Argyllshire in Scotland and in some counties in Munster, Ireland. Welsh slates are largely exported to Germany and Australia. In the United States not far from one-half of all the slates produced are quarried in Pennsylvania, but Vermont, Maine, New York, Maryland, and Virginia also yield large quantities. Slate is known to be plentiful in Arkansas, California, Utah, and in Canada. The annual value of the slates quarried in the States is over £700,000 (£717,680 in 1889). The debris of slate-quarries is made into bricks. 'Enamelled slate' mantelpieces are made of slate painted and stoved.



In roofing with slates it is necessary to put them on in two thicknesses, so that the sloping joints may be covered by the overlap of the course above. Besides this, the third course must also cover the first by an inch or two, to prevent rain from penetrating. Slates are generally laid upon boarding, and bedded in lime, and nailed with malleable-iron nails, galvanised, so as to prevent them from rusting. When large strong slates are used they may be nailed to strong laths in place of boarding. Welsh slates are the smoothest and most generally used; but Argyllshire slates are stronger and better when the roofs are liable to be injured. See D. C. Davies, *Slate and Slate-quarrying* (3d ed. 1887).

Slate-pencils are either cut or turned sticks of soft slate, or they are made by pressing moistened slate powder until it is firm enough to be made into pencils.

Slaughter-houses, or ABATTOIRS, premises in which cattle are slaughtered and prepared for human food. In modern Europe France took the lead in attending to this important matter; a commission appointed by Napoleon issued in the construction in 1818 of the five Parisian abattoirs, which served as the model to other towns and countries. London cannot be said to have followed suit till the Islington market was opened in 1855. Edinburgh has had a well-appointed abattoir since 1851; and in the United States many cities have provided carefully for this important public necessity. Sanitary authorities are agreed that the establishment of a public abattoir under proper supervision tends to ensure the supply of wholesome meat, but neither the English Public Health Act of 1867 nor the Local Government Act, 1889, gives powers to erect or maintain such premises. A number of towns, however, have secured the authority by local bills. Buildings for this purpose should be removed from the vicinity of habitations and should be substantially built. The walls should be tiled or cemented, or otherwise rendered impervious to moisture, for a height of at least 6 feet. Wood-work should be avoided as much as possible consistent with convenience, and what there is should be well painted and frequently washed. To prevent absorption of the fluids and subsequent decomposition, the floor should be composed of roughened cement sloping to a channel. In large slaughter-houses the blood is usually contracted for, and is collected in metal pails and afterwards treated for the manufacture of blood albumen, the residue being dried for manure. Offal should be at once removed from the actual slaughtering-house, and a separate building provided for the washing and preparing of tripe.

Slave-coast, a division of the coast of Upper Guinea, Africa, extending eastwards from the Gold Coast (q.v.) as far as the river Benin, is divided between Germany, Dahomey, France, and Great Britain. The British portion is treated of under Lagos (q.v.), the German under Togo (q.v.), and the French under Senegambia (q.v.).

Slavery, in the fullest sense of the term, implies that the slave is the property or at the disposal of another, who has a right to employ or treat him as he pleases; but the system has been subjected to innumerable limitations and modifications. Slavery probably arose at an early period of the world's history out of the accident of capture in war. Savages, in place of massacring their captives, found it more profitable to keep them in servitude. All the ancient oriental nations of whom we have any records, including the Jews, had their slaves. The Hebrews were authorised by their law to possess slaves, not only of other races, but of their own nation. The latter were generally insolvent debtors who had sold themselves through poverty or thieves who lacked the means of making restitution; and the law dealt with them far more leniently than with stranger slaves. They might be redeemed, and if not redeemed became free in the space of seven years from the beginning of their servitude; besides which there was every fiftieth year a general emancipation of native slaves.

Greek Slavery.—In the Homeric poems slavery is the ordinary destiny of prisoners of war; and the practice of kidnapping slaves is also recognised—Ulysses himself narrowly escaping a fate of this kind. None of the Greek philosophers considered the condition of slavery objectionable on the score of morals. Aristotle defends its justice on the ground of a diversity of race, dividing mankind into the free and the slaves by nature; while Plato only desires that no Greeks should be made slaves. One class of Greek slaves were the descendants of an earlier and conquered race of inhabitants, who cultivated the land which their masters had appropriated, paid rent for it, and attended their masters in war. Such were the Helots in Sparta, the Penestæ in Thessaly, the Bithynians at Byzantium, &c., who were more favourably dealt with than other slaves, their condition somewhat resembling that of the serfs of the middle ages. They could not be sold out of the country or separated from their families, and were even capable of acquiring property. Slaves obtained by purchase were the unrestricted property of their owners, who could dispose of them at pleasure. In Athens, Corinth, and the other commercial states they were very numerous, and were mostly barbarians. They were employed partly in domestic service (some being *pædagogi*, employed to accompany the boys to school, &c.), but more as bakers, cooks, tailors, or in other trades, in mines and manufactories, as labourers on country estates, and as seamen and oarsmen; and their labour was the means by which the owner obtained profit for his outlay in their purchase. These slaves were for the most part purchased; but many were born in their master's family. The Athenian state employed public slaves as police, as soldiers, public criers, gaolers, &c. An extensive traffic in slaves was carried on by the Greek colonists in Asia Minor with the interior of Asia; another source of supply arose from the practice common among Thracian parents of selling their children. In Greece in general, and especially at Athens, slaves were mildly treated, and enjoyed a large share of legal protection. According to Demosthenes, a slave at Athens was better off than a free citizen in many other countries. Manumissions were frequent. A master could obtain damages if a slave was maltreated. The slave was not allowed to wear his hair long, was prevented from entering the gymnasia and public assemblies, but had access to temples and festivals. In the palmy days of the Athenian state there were, according to Wallon, 200,000 slaves in Attica; about three times the number of freemen!

Roman Slavery differed in some particulars from that of Greece. All men were considered by the Roman jurists to be free by natural law; while slavery was regarded as a state contrary to natural law, but agreeable to the law of nations, when a captive was preserved, instead of being slain (the name was believed on doubtful etymological grounds to be '*servus*, quasi *servatus*'); or agreeable to the civil law, when a free man sold himself. In earlier times there was no restriction on the master's power of punishing or putting to death his slave, which was generally carried out by crucifixion; and even at a later period, when the law on this head was much modified, slaves were used with great rigour. The estimation in which their lives were held is illustrated by the gladiatorial combats. Old and useless slaves were often exposed to starve in an island of the Tiber. Under Spartacus (q.v.) a rebellion of slaves attained alarming dimensions. In the time of the empire the cruelty of masters was in some degree restrained by law. It was enacted that a man who put to death his own slave without cause should be dealt with as if the slave had been the property of another; and that if the cruelty of the master was intolerable he might be compelled to sell the slave. Slaves could contract a kind of marriage called *Contubernium;* and ultimately this relation was regarded as indissoluble. The children of a female slave followed the status of their mother. There were various ways in which a slave might be manumitted, but the power of manumission was restricted by law. The harbouring of a runaway slave was illegal. The number of slaves in Rome, originally small, was increased much by war and commerce; and the cultivation of the soil came in the course of time to be entirely given up to them. During the later republic and empire persons in good circumstances kept an immense number of slaves as personal attendants; and the possession of a numerous retinue of domestic slaves was matter of ostentation—200 being no uncommon number for one person. A multitude of slaves were also occupied in the mechanical arts and the games of the amphitheatre. Originally a slave was incapable of acquiring property, all his acquisitions belonging to his master; but when slaves came to be employed in trade this condition was mitigated, and it became the practice to allow a slave to consider part of his gains, called his *peculium*, as his own, a stipulation being sometimes made that he should purchase his freedom with his peculium when it amounted to a specific sum. Having no legal standing, a slave could not give evidence.

Though the introduction of Christianity did not do away with slavery, it tended to ameliorate the condition of the slave. The fathers taught that the true slavery is not that of the body, but the slavery of sin; and Chrysostom thought the apostle did not insist on the suppression of slavery because it was desirable that men should see how truly the slave could enjoy liberty of soul. Constantine allowed poor parents to sell their children into slavery. Justinian, though his Constitution (529 A.D.) drew a very sharp line between slaves and freemen, did something to promote the eventual extinction of slavery; the church excommunicated slave-owners who put their slaves to death without warrant from the judge. But it was not till the reign of Basil (867-886) that the slaves' *contubernium* was hallowed by the blessing of the church. The number of slaves again increased; multitudes being brought with them by the barbarian invaders, who were mostly Slavonic captives (whence our word *slave*); and in the countries which had been provinces of the empire slavery continued long after the empire had fallen to pieces. The doctrine of Von Maurer and Sir Henry Maine has till of late found almost universal acceptance—that the original basis of Germanic societies was a Village Community (q.v.) of freemen owning the land in common, and that slavery arose by degradation of this social condition. But the researches of Fustel de Coulanges and others tend to show that the evidence for Von Maurer's view is slender, and that probably the earliest state of landed property amongst the Teutonic tribes was manorial lordship with slavery as an adjunct. In Britain great numbers of the Celtic or other natives were enslaved by the Anglo-Saxons; and the Christian Anglo-Saxons had a regular trade with the Continent in Irish slaves, Bristol being a great slaving port. After the Norman Conquest slaves as in a separate class ceased to exist, and slavery eventually merged into the mitigated condition known as serfdom, which prevailed all over Europe in the middle ages, and has been gradually abolished in modern times. But though the practice of selling captives taken in war as slaves ceased in the Christian countries of Europe, a large traffic in slaves continued among Mohammedan nations, by whom Christian captives were sold in Asia and Africa; and in the early middle ages the Venetian merchants traded largely in slaves, whom they purchased on the coast of Slavonia, to supply the slave-markets of the Saracens. The history of the achievements of the Barbary corsairs is not to the glory of the Christian nations of Europe. These professional sea-robbers continued for centuries—down to 1812, indeed—to harry the coasts and the commerce of Europe, carrying large numbers of Christians into all but hopeless captivity. When Cervantes was for five years a slave he had about 25,000 fellow-captives in Algiers alone, some treated fairly well, some with great barbarity. Cervantes was ransomed for about £100; £30 or £40 was a more usual price. Another famous slave was St Vincent de Paul. The order of Trinitarians (q.v.) was founded in 1198 for the purpose of redeeming captives (especially French) out of the hands of the infidels, sometimes bringing away several hundreds at a time; and in the 18th century it was not unusual in English and Scottish churches to make collections for a like purpose (see CORSAIR, GALLEY). Christians sent to the galleys by their own or foreign authorities were worse off than domestic slaves. English convicts used to be transported to what was practically slavery in His Majesty's Plantations (see PRISONS, Vol. VIII. p. 417); and convict labour is still a kind of judicial slavery for life or a term of years.

Serfdom—A numerous class of the population of Europe known as serfs or villeins were in a state of what was almost tantamount to slavery during the early middle ages. In some cases this serf population consisted of an earlier race, who had been subjugated by the conquerors; but there were also instances of persons from famine or other pressing cause selling themselves into slavery, or even surrendering themselves to churches and monasteries for the sake of the benefits to be derived from the prayers of their masters. Different as was the condition of the serf in different countries and at different periods, his position was on the whole much more favourable than that of the slave under the Roman law. He had certain acknowledged rights—and this was more particularly the case with the classes of serfs who were attached to the soil. In England, prior to the Norman Conquest, a large proportion of the population were in a servile position, either as domestic slaves or as cultivators of the land. The humblest was nearly a slave—the *theow*; the other the *ceorl* (q.v.), an irremovable tiller of the ground. The powers of the master over his serf were very extensive, their principal limitations being that a master who killed his serf was bound to pay a fine to the king, and that a serf deprived of his eye or tooth by his master was entitled to his liberty. And English serfdom was always territorial rather than personal. After the Norman Conquest there were various names used for the serfs, who seem ultimately all to have been confounded in one class, though originally different. The *villein* (*villanus*) was the Anglo-Saxon *ceorl*; less favourably situated were the *bordarii*; but the Anglo-Saxon *theow* (the *servus*) was no longer part of the system of society. Other names in the Norman period were *rustici* and *nativi*. Soon the difference became at most one of degree; and *serf* and *villein* are used almost indiscriminately for the great group of non-freemen. They were incapable of enjoying anything like a complete right to property, inasmuch as it was held, in accordance with the principles of the Roman law, that whatever the slave acquired belonged to his lord, who might seize it at his pleasure. The master could transfer them to any other master with the land they tilled. They could not even buy their freedom; and they could not educate their sons for the church without the consent of the lord. If the villein ran away he could be pursued and carried back. But if his lord maltreated him he might have remedy in the king's court; and the law defended him fully against injury from strangers. His oath was accepted as evidence. He was often kindly used by his lord, and generally allowed to lay by his savings. He was free from military service, and had a powerful friend in the church. It used to be said that as distinguished from these *villeins regardant* there were also a distinctly lower class of *villeins in gross* who had no political rights, and might be sold away from the land as absolute chattels of the lords; but this is now denied on good evidence. By a peculiarity in the usages of Britain, the condition of a child as regards freedom or servitude followed the father, and not the mother, and therefore the bastards of female villeins might be free.

The abolition of serfdom in western Europe was a very gradual process, various causes having combined to bring it about. The church did not as such denounce the practice of keeping Christians in bondage; indeed, churches and monasteries were amongst the largest proprietors of serfs. But churchmen insisted on humane treatment and practised manumission to a large extent. In the course of time usage greatly modified the rights and liabilities of the serf, whose position must have been considerably altered when we find him making stipulations regarding the amount of his services, and purchasing his own redemption. The towns afforded in more than one way a means of emancipation. A serf residing a year in a borough without challenge on the part of his lord became *ipso facto* a free man. The serf's condition improved gradually but steadily, until he had all the rights of a citizen save against his lord, who required from him the customary services in cultivating the lord's lands; and his hold on his land became a kind of definite tenure of villeinage. The Black Death (q.v.) checked the progress, but only for a time. But the serf's position became by custom more secure and more independent. Serfdom died out in England without any special enactment; yet it was not wholly extinct in the later half of the 16th century, for we find a commission issued in 1574 by Queen Elizabeth, to inquire into the lands and goods of all her bondsmen and bondswomen in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy all their lands and goods as freedmen. In a few rare instances liability to servile duties and payments in respect of lands seem to have continued down to the reign of Charles I. In Scotland as in England serfdom disappeared by insensible degrees; but a remarkable form of it continued to survive down to the closing years of the 18th century. Colliers and salters were bound by the law, independent of paction, on entering to a coal-work or salt-mine, to perpetual service there; and in case of sale or alienation of the ground on which the works were situated, the right to their services passed without any express grant to the purchaser. The sons of the collier and salter could follow no occupation but that of their father, and were not at liberty to seek for employment anywhere else than in the mines to which they had been attached by birth. Statutes 15 Geo. III. chap. 28 and 39 Geo. III. chap. 56 restored these classes of workmen to the rights of freemen and citizens, and abolished the last remnant of slavery in the British Islands.

In France, though a general edict of Louis X. in 1315 purported to enfranchise the serfs on the royal domain on payment of a composition, this measure seems never to have been carried into effect, and a limited sort of villeinage continued to exist in some places down to the Revolution. In Italy one great cause of the decline of villeinage was the necessity under which the cities and petty states found themselves of employing the peasant population for their defence, whom it became expedient to reward with enfranchisement. In the 11th and 12th centuries the number of serfs began to decrease, and villeinage seems no longer to have had an existence in Italy in the 15th century. Joseph II. abolished serfdom in Bohemia and Moravia in 1781, and in the German lands in 1782. Over a large portion of Germany the mass of the peasants had acquired their freedom before the end of the 13th century, but in some parts of the Prussian dominions a modified villeinage (*leibeigenschaft*) continued to exist until swept away by the reforms of Von Stein in the 19th century.

In Russia serfdom remained a part of the social system until 1861; see RUSSIA, pp. 44, 47.

Negro Slavery existed from the earliest times; the Carthaginians seem to have brought caravans of slaves from various parts of North Africa; but in this the negroes suffered no more than other contemporary barbarians. The negro slavery of modern times was a sequel to the discovery of America. Prior, however, to that event the negroes, like other savage races, enslaved those captives in war whom they did not put to death, and a considerable trade in slaves from the coast of Guinea was carried on by the Arabs. The deportation of the Africans to the plantations and mines of the New World doubtless raised the value of the captive negro, and made slavery rather than death his common fate; while it may also have tempted the petty princes to make war on each other for the purpose of acquiring captives and selling them. The aborigines of America having proved too weak for the work required of them, the Portuguese, who possessed a large part of the African coast, began the importation of negroes, in which they were followed by the other colonisers of the New World. The first part of the New World in which negroes were extensively used was Hayti in St Domingo. The aboriginal population had at first been employed in the mines; but this sort of labour was found so fatal to their constitutions that Las Casas (q.v.), Bishop of Chiapa, the celebrated protector of the Indians, interceded with Charles for the substitution of African slaves as a stronger race. As early as the beginning of the 16th century a good many Africans were already in Hispaniola; the emperor accordingly in 1517 authorised a large importation of negroes from the establishments of the Portuguese on the coast of Guinea. Sir John Hawkins (q.v.) was the first Englishman who engaged in the traffic, in which his countrymen soon largely participated, England having exported no fewer than 300,000 slaves from Africa between the years 1680 and 1700; and between 1700 and 1786 imported 610,000 into Jamaica alone. At first the trade was in the hands of special companies, one of which long enjoyed the special right or Assiento (q.v.) from Spain of supplying slaves. Most of the English slaving ships belonged first to Bristol, and from 1730 onwards to Liverpool (q.v.). The slave-trade was attended with extreme inhumanity; the ships which transported the negroes from Africa to America were overcrowded to such an extent that a large proportion died in the passage; and the treatment of the slave after his arrival in the New World depended much on the character of his master. Legal restraints were, however, imposed in the various European settlements to protect the slaves from injury; in the British colonies courts were instituted to hear their complaints; their condition was to a certain extent ameliorated, and the flogging of women was prohibited. But while slavery was thus legalised in the British colonies, it was at the same time the law of England (as decided in 1772 by Lord Mansfield in the case of the negro Somerset, and less emphatically by other judges at earlier dates, without any actual statute on the subject) that as soon as a slave set his foot on English soil he became free; though, if he returned to his master's country, he could be reclaimed. Up till this date the contrary impression was the usual one, though public opinion was strongly setting against the custom of keeping slaves. In 1764 there were believed to be thousands of negro slaves in London; and advertisements of 'black boys' for sale were frequent, as also rewards offered for runaways. As late as November 1771 the *Birmingham Gazette* advertised the public sale of a negro boy, sound, healthy, and of a mild disposition.

Before the idea of emancipation was contemplated the efforts of the more humane portion of the public were directed towards the abolition of the traffic in slaves, mainly under the influence of a sense of Christian duty. In 1787 a society for the suppression of the slave-trade was formed in London, numbering Thomas Clarkson and Granville Sharp among its original members. The most active parliamentary leader in the cause was William

Wilberforce, and Zachary Macaulay was one of its most zealous friends. The Quakers were the only religious body who as such petitioned the House of Commons on the subject. Many not unkindly people defended slavery. Thus Boswell, who on this point opposed his master, speaking of 'so very important and necessary a branch of commercial interest,' says: 'To abolish a status which in all ages God has sanctioned and man has continued would not only be robbery to an innumerable class of our fellow-subjects, but it would be extreme cruelty to the African savages, a portion of whom it saves from massacre and introduces to a much happier life' (*Life of Johnson*, chap. xxxv.). In 1788 an order of the crown directed that an inquiry should be made by a committee of the Privy-council into the state of the slave-trade; and an act was passed to regulate the burden of slave-ships and otherwise diminish the horrors of the middle passage. A bill introduced by Wilberforce for putting an end to the further importation of slaves was lost in 1791, but in 1792 Wilberforce, supported by Pitt, carried a motion to gradually abolish the slave-trade. And it is noteworthy that the anti-Christian French convention, influenced by the teaching of Rousseau, decreed (4th February 1794) that slavery should be abolished throughout the French colonies, and all slaves admitted to the rights of French citizens. Meanwhile, conquest of the Dutch colonies having led to a great increase in the British slave-trade, an order in council in 1805 prohibited that traffic in the conquered colonies; and in the following year an act was passed forbidding British subjects to take part in it, either for the supply of the conquered colonies or of foreign possessions. In the same year a resolution moved by Fox for a total abolition next session was carried in the Commons, and, on Lord Grenville's motion, adopted in the Lords; and the following year the general abolition bill, making all slave-trade illegal after 1st January 1808, was introduced by Lord Howick (afterwards Earl Grey) in the House of Commons, was carried in both Houses, and received the royal assent on 25th March 1807. British subjects, however, continued to carry on the trade under cover of the Spanish and Portuguese flags; the slave-ships were more crowded than ever, to reduce the chances of capture, and the negroes were not unfrequently thrown overboard on a pursuit. The pecuniary penalties of the act were discovered to be inadequate to put down a traffic so lucrative as to cover all losses by capture. Brougham therefore in 1811 introduced a bill, which was carried unanimously, making the slave-trade felony, punishable with fourteen years' transportation, or from three to five years' imprisonment with hard labour. An Act of 1824 declared it piracy, and, as such, a capital crime, if committed within the Admiralty jurisdiction; and the statute of 1837, mitigating the criminal code, left it punishable with transportation for life. The Anti-slavery Society practically established the colony of Sierra Leone in 1787 as a home for destitute negroes.

The United States of America abolished the slave-trade immediately after Great Britain (1808), and the same was in the course of time done by the South American republics of Venezuela, Chili, and Buenos Ayres, by Sweden, Denmark, Holland, and, during the Hundred Days after Napoleon's return from Elba, by France. Great Britain, at the peace, exerted her influence to induce other foreign powers to adopt a similar policy; and eventually nearly all the states of Europe have passed laws or entered into treaties prohibiting the traffic. The accession of Portugal and Spain to the principle of abolition was obtained by treaties of date 1815 and 1817; and by a convention concluded with Brazil in 1826 it was declared piratical for the subjects of that country to be engaged in the slave-trade after 1830. By the conventions with France of 1831 and 1833, to which nearly all the maritime powers of Europe have since acceded, a mutual right of search was stipulated within certain seas, for the purpose of suppressing this traffic. The provisions of these treatises were further extended in 1841 by the Quintuple Treaty between the five great European powers, subsequently ratified by all of them except France. The Ashburton treaty of 1842 with the United States provided for the maintenance by each country of a squadron on the African coast; and in 1845 a joint co-operation of the naval forces of England and France was substituted for the mutual right of search.

The limitation of the supply of negroes naturally led, among other good results, to a greater attention on the part of the masters to the condition of their slaves. But the attention of British philanthropists was next directed towards doing away with slavery altogether in the colonies. Societies were formed with this end, an agitation was set on foot, and attempts were made, for some time without success, to press the subject of emancipation on the House of Commons. At length in 1833 a ministerial proposition for emancipation was introduced by Mr Stanley (Earl of Derby), then Colonial Secretary, and an emancipation bill passed both Houses, and obtained the royal assent 28th August 1833. This act, while it gave freedom to the slaves throughout all the British colonies, at the same time awarded an indemnification to the slave-owners of £20,000,000. Slavery was to cease on 1st August 1834; but the slaves were for a certain duration of time to be apprenticed labourers to their former owners. Objections being raised to the apprenticeship, its duration was shortened, and the complete enfranchisement took place in 1838. The serious decadence of trade and commerce in the British West Indies has been commonly attributed to emancipation; but though the change in the position of the negroes unquestionably contributed to the result, it is clear that before a slave had been manumitted by law the industry of Jamaica and the other islands had already begun to fall off.

The French emancipated their negroes in 1848; as did most of the new republics of South America at the time of their establishment; while the Dutch slaves had freedom conferred on them in 1863. In Hayti slavery ceased as far back as 1791, its abolition having been one of the results of the negro insurrection of that year. In Brazil (q.v.) slavery was not abolished until 1888.

The history of negro slavery in the United States is partly dealt with at Negroes (q.v.); the steps that hindered or prepared the way for its final abolition in 1862-65 are part of the history of the United States (q.v.), and are dealt with in such articles as ABOLITIONISTS, BROWN (JOHN), DRED SCOTT CASE, GARRISON, LINCOLN, MISSOURI (for the 'Missouri Compromise'), &c. Here it may be noted that in 1800 there were in the United States 893,041 slaves; that Vermont, Pennsylvania, Massachusetts, Rhode Island, Connecticut, New York, and New Jersey emancipated their slaves before 1840, most of them by gradual measures. The average value of slaves was about this period stated at $600. The 3,953,760 slaves at the census of 1860 were in what were known as the Southern States. Eminent leaders of public opinion from the earliest period of the national existence—such as Washington, Franklin, Jefferson, Madison, Jay, Hamilton—regarded slavery as a great evil, and inconsistent with the principles of the Declaration of Independence. The Society of Friends uniformly opposed slavery, and agitated against it. The Presbyterian Church made six formal declarations against it between

1787 and 1836. The Methodist Episcopal Church always cherished strong anti-slavery views; though when in 1844 one of their bishops was suspended for refusing to emancipate slaves he had inherited through his wife, a secession took place, and the Southern Methodist Episcopal Church was formed. Individuals and groups of persons of almost all churches were found defending slavery. In 1835 the Charleston Baptist Association resolved that the right of masters to dispose of their slaves had been distinctly recognised by the Creator. In 1836 a North Carolina bishop strongly commended for publication a sermon which declared that without a new revelation from heaven no man was authorised to pronounce slavery wrong. In 1838 the New School Presbyterian Church in Petersburg, Virginia, protested against a resolution of the General Assembly declaring slavery a sin against God, pronounced that resolution irreconcilable with American civil institutions, and affirmed that the relation of master and slave had been recognised by the great Head of the Church. Yet, on the whole, anti-slavery views grew steadily; but until the crisis of the civil war very many of those who personally held strong anti-slavery opinions hesitated to join actively in abolitionist agitation, as unwilling to invade what many of their fellow-citizens held to be their indisputable rights. To this halting attitude the war put an end.

Mohammedanism (q.v.) recognises the institution; Mohammed's own precepts insist on the kindly usage of the slave; and Moslem slavery is mainly domestic slavery, household slaves being on the whole well treated. But there is no more awful chapter in the history of human callousness and human misery than the story of the slave-trade as carried on by 'Arab' or Moslem slave-traders, its main tracks from the interior of Africa to the coast being still in many places marked by the whitened bones of slaves who during the ages have sunk in the way, fallen out of the caravans in spite of the lash, and have died or been slaughtered to save trouble. The main regions from which slaves were procured for the Moslem East were, or still are, the Soudan proper, the Egyptian Soudan, or Valley of the Upper Nile, Somali Land, and the borders of the Portuguese East African territory. English and other men-of-war have long been employed in capturing slave-dhows on the east coast. In 1869 the Egyptian Khedive Ismail gave Sir Samuel Baker large powers for the suppression of the slave-trade, a crusade carried on by Gordon Pasha. The sultan of Zanzibar signed a treaty for the suppression of the trade in 1873. By occupying Caucasia, Russia stopped an important supply for the Turkish harems; it also closed the slave-markets of Khiva and Bokhara, and by crushing the Turkomans (Tekkes and others) freed at once 40,000 slaves. Cardinal Lavigerie, who became archbishop of Algiers in 1867, made the suppression of the slave-trade and slavery his life work, and secured the help of many zealous fellow-workers, men and women. The progress of the Congo Free State, the foundation of missions in the Nyassa country, and the encouragement of legitimate trade by the British East Africa Company and the German settlements will, it is hoped, tend still more effectually to put an end to this curse of mankind. It has been said that the African slave-trade will not finally cease till the African elephant is extinct, as the carrying of ivory to the coast has heretofore only been practicable by slave labour. Conferences of the civilised powers have repeatedly been held with a view to the further restriction of domestic slavery (the entire suppression of which at once is hopeless) and the total prevention of the slave-trade.

Slavs, or SLAVONIANS (native name, *Slovene* or *Slovane*, probably connected with *slovo*, 'a word,' thus meaning the people who spoke intelligibly as distinguished from their neighbour, *Niemets*, the German, literally the 'dumb man;' this opinion is held by the majority of scholars, but lacks the support of Miklosich, who considers both to be tribal names), the general appellation of a group of nations belonging to the Aryan family, whose settlements extended from the Elbe to Kamchatka, from the Frozen Sea to Salonica, the whole of eastern Europe being occupied almost exclusively by them. They were settled in this continent before the historical times, as their migrations are never mentioned, and some modern scholars—Penka, Poesche, and others—regard them as inhabitants of Europe from the earliest period, and even assign the cradle of the human race to White Russia. It seems probable from the description given in the fourth book of Herodotus that at least one of the Scythian tribes, the Budini, was Slavonic, and to it may perhaps be added that of the Neuri. The original names of the Slavonic tribes seem to have been Winds or Wends (*Venedi*) or Serbs. The former of these names occurs among the Roman writers, and later, in Jordanis, in connection with the commercial peoples of the Baltic; the latter is spoken of by Procopius as the ancient name common to the whole Slavonic stock. The earliest historical notices represent the Slavs as having their chief settlements about the Carpathians, from which they spread northward to the Baltic, westward as far as the Elbe and the Saal, and later, after the overthrow of the kingdom of the Huns, southward beyond the Danube, and over the whole peninsula between the Adriatic and the Black Sea. These migrations ceased in the 7th century; the division of the Slavonic stock into separate branches became now more complete, and gradually they began to form independent states. The sections of the stock may be divided into two groups, the south-eastern and the western; the first comprehends (1) the Russians, (2) Bulgarians, (3) Illyrians (Serbs, Croats, and Slovenes); the second (1) Lechs (Poles, Silesians, Pomeranians), (2) Czechs or Bohemians (Czechs or Chekhs, Moravians, Slovaks), (3) the Slavonic tribes of north Germany, among whom are to be reckoned the Polabes. The only tribes who have preserved their language are the Lusatian Wends or Sorbs dwelling in Saxony and Prussia. Of the Polabes there are now no traces; their language ceased to be spoken in the early part of the 18th century. Many of the old Slavonic states have lost their independence and are in a state of greater or less vassalage. At the present time Russia, Servia, and Montenegro are wholly independent. Bulgaria is a tributary state of Turkey, but practically independent. Bohemia and Moravia are united to Austria, and Croatia forms part of the kingdom of Hungary. Poland is distributed between Russia, Austria, and Prussia. Some Slavonic tribes have never enjoyed independence—e.g. the Sorbs and Slovenes. The sum total of the Slavonic populations is estimated at about 100,000,000.

The Slavs are represented by ancient writers as an industrious race, living by agriculture and the rearing of flocks and herds; as hospitable and peaceful, and making war only in defence. The government had a patriarchal basis, and chiefs were chosen by the assemblies. But in the west contact with the feudal institutions of the German empire, and in the east with Byzantium and the Mongols, greatly altered this primitive constitution; the Slavonic princes aimed at unlimited power, and the chiefs succeeded in binding the free peasants to the soil, as the feudal nobility had done. In the course of the 11th, 12th, and 13th centuries a hereditary nobility was formed in some of the Slavonic states. The people sank into the lowest condition of serfdom. Between them and the nobles there was no third or middle class, as the privileges of the nobility prevented the growth of towns, and such trade as there was was chiefly in the hands of foreigners.

The *religion* of the ancient Slavs, like that of the Teutonic nations, seems to have been in many of its features a kind of nature-worship—not without, perhaps, a predominating divinity: at least so Procopius tells us. But the whole subject of Slavonic mythology is up to the present time in a very confused state. For our information about Slavonic deities we are indebted to Nestor and the German chroniclers who wrote about the Baltic Slavs—e.g. Thietmar, Helmold, and others. We thus only know the gods of these peoples and the Russians. About those of the Poles, Bohemians, and southern Slavs we know almost nothing. The idols, from the accounts given of them, appear to have been of wood; and this is probably the reason why no genuine remains of them have come down to us. The chief deity, whose worship was probably common to all the western Slavs, was Sviatovit, with whom may be associated Perun and Radegast—and some have thought that these three names denote different personations or manifestations of the same power. Perhaps we may find parallels in Sviatovit to Mars and Zeus, Perun to Jupiter and Thor, and Radegast to Mercury and Odin. Of gods of an inferior order we may name Prowe, perhaps a god of justice, and Chernobog, the black god, together with multitudes of demons and spirits good and bad. Thus, among the Russians there were *rusalki*, water-nymphs, *lieshie*, satyrs; and among the Serbs and Bulgarians, *vilas* and *samodivas*, a kind of malicious fairy.

Some of these deities were worshipped under monstrous forms: thus, Sviatovit had four heads, Rugewit, the god of war, had seven faces, and so on. The Slavs seem to have had some crude notion of existence and retribution after death. Worship was performed in groves and temples, cattle and fruits being offered by the priests, whose office was originally performed by the head of the family or chieftain; perhaps this may be the reason why there is a common name for priest and prince (*knez*) among the western Slavs: the word, however, is certainly borrowed from the O. H. Ger. *chuning*. The eastern Slavs received Christianity from Byzantium in the 9th century, through the instrumentality of Cyril (q.v.) and Methodius; the western from Rome and Germany. They were Christianised with little opposition, for they had no religious caste, and there were no persons politically or socially interested in the cultus of their idols. Panslavism is the subject of an article (q.v.). See Schafarik, *Slavische Alterthümer*.

SLAVONIC LANGUAGE.—The term Slavonic, as applied to language or race, is a generic name (like Celtic or Teutonic) for a group of kindred languages and people belonging to the great Indo-European or Aryan family. The Slavonic languages are in a highly inflected state: the noun has seven cases, and all the numerals are declined. An article is implied in the termination of the adjective, as is shown by the form which it assumes when used as a predicate. As regards tenses, Russian, Polish, and Bohemian in their modern forms have lost the imperfect and aorist, but they are preserved in the Serbo-Croatian and Bulgarian. The poverty of the tense-system is amply compensated by the so-called *aspects*, which are found in every Slavonic verb—e.g. the frequentative, the momentaneous, and others, which supply tenses that may be wanting to the simple verb and express very delicate distinctions of time and manner. The Slavonic family in preserving these aspects has been truer to the old Aryan type of language than Teutonic. Traces of them can be seen in Greek (as Curtius has shown) and in Old Irish. The prepositions in and out of composition are used with a delicacy reminding us of ancient Greek. These languages have great power of compounding words and rich vocabularies. The oldest form known is the Palæo-Slavonic or ecclesiastical Slavonic, so called because used in the Orthodox churches. The original home of this language has been the subject of much dispute, and has divided Slavists into two camps; some finding it in Bulgaria, others in the ancient Pannonia, now corresponding to the territory occupied by the Slovenes —viz. Styria, Carinthia, and Carniola; hence it is sometimes called Old Bulgarian and sometimes Old Slovenish. It is, however, only an elder sister and not a mother language. The Slavonic family of languages may be grouped as follows: first, the south-eastern branch—(1) Russian, including Malo-Russian and White Russian. The second of these has great claims to be considered a distinct language, and is so treated by Miklosich. (2) Old and modern Bulgarian, the latter being in a somewhat decomposed form, having lost nearly all its cases and the infinitive mood. (3) Serbo-Croatian. (4) Slovenish. Secondly, the western—(1) Polish, including Kashubish. (2) Bohemian, including Slovak. (3) Lusatian-Wendish, or Sorbish, divided into two sharply defined dialects. (4) Polabish, which died out at the beginning of the 18th century, and like Cornish has been preserved in some vocabularies, &c.: from these fragments Schleicher constructed a grammar. See the sections on language and literature in the articles BOHEMIA, POLAND, RUSSIA, and SERVIA. We may here remark that in literature Russian, Polish, or Bohemian are richest, the two latter nations having developed a literature much earlier than the former. This remark applies especially to Bohemian, which can show good prose-writing in the 14th century. Many of the Russian and Polish poets have great merit. Slovenish and Sorbish are poor. The Serbs have developed a respectable literature in the 19th century, and the Bulgarians are already active. But both have only recently shaken off the Turkish yoke, fatal to all progress. Serbian, Russian, and Bulgarian are very rich in old ballads and popular songs. These are scanty in Bohemian, and almost entirely wanting in Polish. Old Bulgarian literature, such as it has come down to us, consists mainly of religious works, original and translated.

See Pypin and Spasovich, *Istoriya Slavianskikh Literatur* ('History of Slavonic Literature,' in Russian, 1879; there is a German translation); Miklosich, *Vergleichende Grammatik der Slavischen Sprachen* (4 vols. Vienna, 1879); Leskien, *Altbulgarisches Lesebuch* (2d ed. 1886). For grammars of special languages, see under respective headings. And see Talvi (Mrs Robinson), *Literature of the Slavic Nations* (New York, 1850); *Slavonic Literature*, by the present writer, W. R. Morfill (Lond. 1883).

Sleaford, a town of Lincolnshire, on the right bank of the Slea, a branch of the Witham, 17 miles SSE. of Lincoln. It has a fine church (built in 1271), a grammar-school (1624), and a monumental cross (1850). Here King John fell sick after crossing the Wash, and whilst spending the night in the old castle (now almost wholly disappeared). Pop. 4965.

Sledge. See SLEIGHS.

Sleep is symptomatic of repose in the brain and nervous system; in those who are awake cerebral activity is unceasing. Potential energy is being constantly expended in mental operations, vital processes, muscular movements, &c.; also in the perception of impressions that stream towards the brain incessantly from every part of the economy and of the environment. This is attended by wear and tear of the nervous textures, and by the deposition in them of waste-products proportionate to the work effected. Waking is therefore a positive condition—one in which energy is consumed more quickly than it is restored, and than the waste-products are eliminated. It is a state that entails a full working blood-supply to the brain. After a time, longer or shorter, a sense of fatigue suggestive of repose supervenes that is only relieved by sleep. Sleep, on the contrary, is a negative state—one in which these processes are reversed. The brain is inactive; consciousness and volition are in abeyance; coincidently the central blood-supply is diminished, the brain is smaller in size, and its temperature is lowered. Expenditure of energy is curtailed to the greatest extent compatible with life. Recuperative processes continue, and predominate over the destructive; the nervous structures are depurated, and potential energy is accumulated. When recuperation is completed awaking occurs, and is accompanied by feelings of invigoration. Waking and sleep, therefore, are indicative of cerebral activity and of cerebral rest; they are both physiological functions of a healthy nervous system. When either is unduly prolonged, curtailed, or modified it gives evidence of a departure from health.

The brain is a composite organ. It contains innumerable centres which dominate an equally vast variety and number of functions; and these require and obtain sleep in varying degrees according to their functions. The supreme (psychical) centres which are constantly alert during waking need more sleep than some of the subordinate centres. These latter rest partially by day, so that the complete abdication of their functions at night is less urgently required.

The incursion of sleep is gradual. It is synchronous with the subsidence of activity in the brain and nervous system, and it is best studied in this connection. Molecular activity does not cease in the whole brain instantly, but in one portion after another until the whole organ becomes tranquil. It is suspended first in the centres situated highest in the cerebrum, and afterwards in those at lower levels, till the medulla oblongata and spinal cord are included. It consequently affects the motor centres of the brain first. The earliest symptom of sleep is the weakening of the voluntary muscles; relaxation takes place in one set after another until the body assumes the horizontal posture. The sphincter muscles are exceptional; they remain contracted. During deep sleep true slackening occurs in the muscular fibres, even in diseases like tetanus and hydrophobia. A man may fall asleep in motion, as in walking or riding, and maintain his equilibrium; a certain amount of activity being sustained in the motor centres enables him to do so. If he yields to sleep in a stationary attitude, the motor centres being quiescent, he tends to sink into the recumbent posture. Activity next wanes in the psychical centres of the brain. The will ceases to control the working of the intellectual faculties, and the perceptive powers are lessened. The mind, no longer inhibited from within nor corrected from without, revels in absurdities until mental operations cease, or, at least, till they are wrapped in oblivion. The centres of the special senses in the brain are next involved, and usually in the following order; they fail to perceive slight or ordinary impressions, while their special nerves transmit them in a slow and imperfect manner. (*a*) Vision: The eyelids close; the eyeballs turn upwards and inwards in the orbits. The eyeballs occasionally, if rarely, move independently, and not in unison, during sleep. The pupils contract—the contraction being in ratio to the depth of sleep; they dilate widely in the act of awaking. (*b*) Hearing: Loud noises interrupt sleep, though an expected noise does so more readily. Monotonous sounds do not prevent or interrupt sleep; their cessation may terminate it. (*c*) Smell: Slight odours may prevent the onset of sleep; but very pronounced smells are required to disturb it. (*d*) Taste: It is difficult to determine the condition of this sense during sleep, the sense of touch being apt to vitiate the conclusion. (*e*) Touch: This is the most sensitive sense during sleep. It is chiefly through it that man is warned of danger, and that his safety is secured. Reflex acts can always be elicited, their vigour depending on the strength of the stimulus, the degree of sensitiveness of the part to which it is applied, and the depth of sleep. The centres in the medulla oblongata then become less active. They chiefly dominate the heart, the lungs, and arterial pressure. The heart beats from ten to twenty times less per minute, and the blood pressure is diminished. The respirations are about four fewer per minute. The inspirations are shallower and chiefly thoracic. The pause between inspiration and expiration is practically absent. Pettenkofer and Voit stated that of the total carbonic acid eliminated in twenty-four hours 58 per cent. is given off during the twelve hours of day and 42 per cent. during the twelve hours of night; whilst 67 per cent. of the oxygen taken in is absorbed during the twelve hours of night and 33 per cent. during the day. The centres that dominate the various secretions only respond to suitable stimuli, and as these are wanting during sleep the secretory organs are less active. The digestive juices are not formed, and if the gastro-intestinal movements do not cease entirely, they are greatly lessened. The urine is secreted in one-fourth the quantity. The quantity of sodium chloride, sulphates, and urea it contains is smaller; the latter is decreased one-half. The secretion of sweat is increased, and that of milk is continued.

In consequence mainly of the inactivity of the bodily functions the bodily temperature falls as much as from 0°·5 to 2° F., chiefly for some hours after midnight; it being lowest about 4 A.M. It falls similarly by day in those who work by night and sleep by day. According to Helmholtz, a man gives off about three times more heat when he is awake than he does when he is asleep. During sleep the economy is more vulnerable to the influence of deleterious surroundings; it has less resisting power. Hence it is that infectious and malarial diseases are so readily contracted by sleeping in places in which these poisons abound; hence also the liability to catch cold from sleeping in a draught. Briefly summarised, during sleep the brain, ganglia, medulla oblongata, and spinal cord are in a state of repose. And the extent to which they are involved may be inferred from the fact that sleeping persons suffer little, if any, from shock in accidents which affect those who are awake most injuriously.

Sleep varies in depth in persons of different ages. It is usually profound in the young, and light in the aged. The depth bears some relation to its duration. Natural sleep varies from time to time during the same night. The observations of Kohlschutter, of Rummo and Ferrannini, and of Monninghoff and Piesbergen showed that it was deepest an hour after its onset, when its intensity decreases quickly, then more slowly, and again it becomes more profound a second time after four to five hours. This is important in sleep-disturbance, for excitations will act more powerfully when it is lightest. On the other hand, when it is deepest the lowest centres are least inhibited, and the blood is less thoroughly oxygenated. It is then that epileptic, convulsive, spasmodic, and such-like seizures are most apt to occur. Cases of sleep lasting for weeks and months have been recorded (that of Johann Latus in the hospital of Myslowitz in Silesia in 1891–92 lasted 4½ months); in Britain it occurs in neurotic patients, and sometimes is called trance. It is pathological and not natural sleep. In western Africa 'sleeping sickness' is a well-known fatal disease.

Cause of Sleep.—For upwards of two thousand years continuous attempts have been made to elucidate the cause of sleep without success; many theories have been promulgated, but they have fallen short of explaining it.

Of *circulatory theories* the one that prevailed during many centuries attributed sleep to a determination of blood to the head; and much evidence was adduced in its support. Nevertheless, congestion of the brain is incompatible in health with good and refreshing sleep. This hypothesis was replaced by the anæmic theory. From the observations of Donders (1854), Durham (1860), Regnard (1868), Hammond and Weir-Mitchell (1869), and Ehrmann, Salathé, and F. Franck (1877), it would seem to be conclusively demonstrated that the blood-supply of the brain is lessened during sleep. Whether this is causative, concomitant, or consequent is still open to conjecture. Pathological anæmia is a well-recognised source of wakefulness. It appears certain that a blood-supply sufficient for nutritive purposes, but insufficient for mental activity, is an essential factor in natural sleep. The brain, like all other organs, governs and is not governed by its vascular supply.

Humboldt suggested one of several *chemical theories*—that sleep was due to the want of oxygen; and many have since urged that everything that deprives the brain of oxygen conduces to sleep. An atmosphere deficient in oxygen, or one containing an excess of carbonic acid, induces drowsiness and sleep, but it is poisoned, and not healthy sleep. Pflügger believed that activity of the psychical cells depends on the quantity of intra-molecular oxygen they contain, and that all function is attended (particularly in the gray matter) by explosive movements in the cells, caused by the combination of oxygen with the tissue-elements, in which oxygen is consumed and carbonic acid is formed. He thought that these movements used up the oxygen at a greater speed than the circulation could replace, and that a time arrived when the lack of oxygen and an excess of carbonic acid caused drowsiness and sleep. Again, it has been urged that the waste-products (resulting from *mental operations*) in the nervous textures occasioned sleep. Preyer believed that the accumulation of these (ponogenes) at first caused fatigue, then sleep, and that waking occurred when they were eliminated in sleep. This doubtless is a factor in the causation of sleep, but it does not explain it.

The absence of external stimuli, such as occurs in the darkness and quietness of night, has been credited with causing sleep. It is a desirable aid to sleep, but, in health, sleep ensues despite all disturbing agencies—even on the torture-rack. Sleep has been ascribed to the law of periodicity that governs all organised things. The study of the bodily functions shows that rest and activity alternate—even the heart gets about ten to twelve hours rest in the pauses between its contractions. Of other numerous theories, it will suffice to say that no one of them can be accepted as fully explaining and finally settling the subtle problem. It may be that the mystery will never be solved until a deeper insight into the working of the mind itself is acquired.

How long should one sleep? is a question that must be answered generally. No hard and fast law can be laid down; every man must be a rule to himself. It is quite clear that nature intends everyone to sleep until the effects of waking are dissipated, and until the bodily energy is renovated. In childhood, when the constructive processes of growth involve large expenditure of energy, sleep is long and profound. In youth much sleep is still needed. In middle age, when decay and repair alone require to be balanced, less sleep is required. In old age, when repair is slowly and imperfectly effected, more sleep is desirable. The duration of sleep is also largely influenced by sex, temperament, occupation, habit of sleep, season, climate, &c. The true guide is the recuperation of the energies; that is indicated by a feeling of well-being on awakening. Some persons awake, after sleeping for an apparently sufficient number of hours, worn, jaded, and exhausted. That is an indication of disease, pointing to an inability on the part of their textures to accomplish their reparation.

Sleeplessness.—The effects of curtailed sleep are very marked. The loss of a single night's sleep is attended by symptoms of enervation; that of several nights' sleep, by serious consequences. In many diseases the lack of sleep determines a fatal issue; conversely, sleep often determines recovery. Few persons appreciate the fact that the voluntary curtailment of sleep for an hour every night for a year is equivalent to the loss of forty-four nights' sleep of eight hours' duration. That represents an enormous expenditure of energy—e.g. during that time the cardiac pulsations are approximately 210,000 and the respirations about 90,000 more frequent than they would have been during sleep. Undue curtailment of sleep is attended by loss of flesh, the essence of emaciation being the preponderance of decay over repair. The skin becomes dry, and it loses its suppleness and translucency. All the bodily textures are badly nourished, and the organs suffer from lack of innervation. When sleep has been limited unduly, inability to sleep ensues and becomes the bane of existence. Exhaustion of the cerebral structures leads to still graver symptoms, such as insanity. Indeed, insomnia preludes or enters to a greater or less extent into the causation of almost every form of mental alienation. They arise from similar causes. Many of the tragedies of life are *due solely to the* prolonged want of sleep. Insomnia or continued sleeplessness may cause death from exhaustion. Sleep, on the other hand, is a powerful curative agent—one that alone suffices to determine recovery. It has been well called 'the chiefest thing in physic.'

Sleeplessness is a symptom designed to subserve a highly conservative purpose. It attracts attention in some to ailments that might otherwise elude detection; in others it maintains consciousness requisite for the preservation of life. Sleeplessness is symptomatic of cerebral activity. This may be originated and perpetuated in divers ways. It may arise from mental causes, for the mind is dependent on the brain for its external manifestation. In mental overwork, worry, grief, suspense, &c. the intellectual or emotional centres respectively grow hyperæmic. At night the vaso-motor nerves that dominate the arterial vessels, worn out by continued inhibition, fail to moderate the supply of blood to these centres, and so the man is impelled to work and to worry, and he is prevented from sleeping. In the early stages he is long in falling asleep, and when he does it is to dream of his work and worry. Eventually insomnia becomes pronounced. Sleeplessness may depend on faulty conditions in the brain itself. Cerebral cells primarily or congenitally feeble, or secondarily debilitated by unhealthy conditions, display their enfeeblement in an incompetency to accumulate nervous force. Their molecules are rearranged in a preternaturally unstable manner, and they discharge their latent energy in response to trifling excitations. Such cells are designated 'explosive.' *The peripheral cells generally participate in the* enfeeblement, and they and their conducting nerves transmit impressions in a rapid and exaggerated manner. The reaction-time is lessened. This is a fruitful source of wakefulness in neurasthenia and its allied conditions. Sleeplessness from this cause usually appears at the epochs of life, and under privations or strains. The patient gets to sleep easily, but awakes in two or three hours, to remain awake till five or six in the morning. The awaking is often attended by distress and misery. It is in this class of cases that insomnia often occurs and recurs mysteriously. All neurotic diseases tend to recur paroxysmally; a bad sleep-habit once acquired is liable to return from time to time from very trivial causes.

Sleeplessness may result from a blood-supply altered either as regards quantity or quality. The cerebral cells are very sensitive to their environment; they bear excess and deprivation badly. Hyperæmia and anæmia of the brain are consequently productive of cerebral unrest and of wakefulness; and these brain-conditions may arise from diseases of the heart, lungs, and other organs, which secondarily implicate the cerebral circulation. The brain textures are unfavourably affected by alterations of vascular tension; high tension is unfavourable to sleep. They are equally disturbed by overheated blood such as pertains to feverish states. They are similarly perturbed by blood contaminated by peccant matters, such as those of gout, rheumatism, syphilis, malaria, &c.; hence the sleep disturbance in these diseases, and also that which follows the excessive use of tobacco, alcohol, &c. In the latter class the patients get to sleep quickly, *to awake at two or three in the morning*, to lie awake for some hours; and they are often awakened by slight external excitations.

Sleeplessness may be originated by sensory stimuli, which cause contraction of the peripheral and dilatation of the cerebral blood-vessels, acceleration of the heart's action, and an increase of arterial tension. They also cause dilatation of *the pupils, and change the character* of the respirations; these become deeper, quicker, and more abdominal. Consciousness of external things can alone be aroused by impressions transmitted to the brain textures (themselves insensitive) becoming converted into sensations and ideas through the agency of the mind. When excitations are of sufficient intensity to cause sensations wakefulness is inevitable. Excitations may be instigated in the most varied ways; they include pain of all kinds, and many impressions arising out of digestive and other derangements. They affect the neurasthenic, gouty, and rheumatic unduly.

It is evident that successful treatment depends on accuracy of diagnosis. In each and every case the sleeping conditions of the sufferer should be attended to. Exercise and food should be proportionate to the body and to the strength of digestion. The primæ viæ and the state of the skin must not be neglected. A good habit of sleep should be assiduously cultivated. In sleeplessness due to mental causes change of work should be advised, that new centres may be called into operation, and the overwrought ones correspondingly relieved. It is in these cases alone that devices for getting to sleep, such as the monotonous counting of figures, sheep, &c., are efficacious. In bad cases the judicious use of pure hypnotics is helpful; they force the mind into oblivion. Drugs, like potassium bromide and chloral hydrate, which act chiefly on the brain centres that function thought, and induce sleep that closely resembles natural sleep, are called pure hypnotics, in contradistinction to many substances, as narcotics, analgesics, anodynes, soporifics, &c., that arrest *pain, diminish sensibility, and disturb* in a pronounced manner the functions of the brain and nervous system.

When wakefulness is due to neurasthenic conditions, tonics, increased nutrition, the abandonment of excesses, change of air and scene are indicated; electricity and suitable baths are useful adjuncts; hypnotics should be sparingly employed. Sleeplessness due to hyperæmic conditions of the brain is to be met by antiphlogistic treatment; that which depends on anæmia, by tonics, &c. In both, posture during sleep will repay attention. That which originates from gouty, rheumatic, syphilitic, and like poisons only yields to the alleviation of the constitutional state.

In sleeplessness due to sensory stimuli and pain, care must be taken to ensure the removal or mitigation of these, that the sleep they prevent may supervene. Medicines—analgesics or anodynes—such as belladonna, should be first selected, for they act as indirect hypnotics by operating chiefly on the nerve-terminals. When such remedies fail, narcotics, as morphine and opium, are called for; they not only lessen perceptivity in the brain and sensitivity in the nerve-endings, but they diminish the conductivity of the nerves. Such wide-reaching drugs have many disadvantages in such cases, but pure hypnotics are useless. Hypnotics, narcotics, and sleep-inducing medicines should never be taken except under medical advice. To drug the brain into quiescence without remedying the cause of the cerebral activity will in many cases only aggravate the evil, for they will be complicated by a drug-taking habit. In most instances drugs are best avoided.

Good bibliographies of this subject are to be found in Copeland's *Dict. of Med.* (vol. iii. pt. 2, Lond. 1858); in *Dict. Encycl. des Sciences Médicales*, art. 'Sommeil' (ser. iii. tom. 10, 1881); also in Neale's *Medical Digest* (Lond. 1891). The following may be consulted in connection with the physiology of sleep: Cappie, *The Intra-*

cranial Circulation (Edin. 1890); Carpenter, *Mental Physiology* (Lond. 1874); Durham, *Physiology of Sleep* (Guy's Hosp. Reports, 1860); Fleming, 'On Sleep,' *Brit. and For. Med. Chir. Rev.* (1865); Hammond, *Wakefulness*, &c. (Phila. 1865); Holland, *Mental Philos.* (Lond. 1858); Lemoine, *Du Sommeil au Point de Vue Phys. et Psychol.* (Paris, 1855); Lyman, *Insomnia* (Chicago, 1885); Marvand, *Le Sommeil et l'Insomnie* (Paris, 1881); Moore, *On Going to Sleep* (Lond. 1868); Mosso, *Sulla Circolaz. del Sangue nel Cervello*, &c. In *Plants*, sleep is one of the phenomena of Irritability (q.v.). Light acts on plants as a powerful stimulus, essential to their active and healthful vegetation. When it is withdrawn the flowers of many plants close, and the greater number show a tendency to it, whilst leaves more or less decidedly incline to fold themselves up. The leaf-stalk also generally hangs down more or less, although in some plants it is more erect during sleep. The sleep of plants, however, is not always nocturnal. The flowers of some open and close at particular hours of the day. Thus, the crocus is a morning flower, and closes soon after mid-day; whilst some flowers expand only in the evening or during the night. It was Linnæus who first observed the sleep of plants in watching the progress of some plants of *lotus*, the seeds of which he had sown. The periodic movements of plants, of which sleep is one, have various uses. The opening of flowers in the morning and the closing in the evening is related to pollination; the folded petals protect the stamens and other sensitive parts from excessive cooling or wetting. The rising and falling of foliage leaves is useful in the same way, and preserves the chlorophyll-bearing tissue from injury; the extended position is adapted for temperatures and intensities of light that are favourable to assimilative activity. See PLANTS (MOVEMENTS OF), and VEGETABLE PHYSIOLOGY.

Sleidanus, JOHANNES, whose proper name was PHILIPPSON, a writer of history, was born at Schleiden, in the neighbourhood of Aix-la-Chapelle, in 1506, and having been trained to the law he entered the service (1537) of Francis I. of France. But becoming a convert to Protestantism he was dismissed (1541); and for the rest of his life he was ambassador of the Protestant princes of Germany, and represented them at the court of England and at the Council of Trent. He died at Strasburg on 31st October 1556. His name lives as the author of a history of the reign of Charles V.—a well-written, impartial work entitled *De Statu Religionis et Reipublicæ Carolo V. Cæsare Commentarii* (1555; best ed. Frankfort, 1785-86, 3 vols.). Baumgarten edited the Letters of Sleidanus (1881) and wrote a Life of him (1878).

Sleighs, or SLEDGES, are travelling vehicles without wheels, which in some form are in use in all countries where snow lies for any considerable part of the year. Usually they are on runners—either one or two pairs—which are connected by a framework and support the body of the vehicle; but the well-known travelling-sledge (*pulkha*) of the Laplanders, built in the form of a canoe, with sharp bow and square stern, of light materials and covered with reindeer skin, has no runners. In the northern United States and in Canada, where sleighs are brought to great perfection, lightness, and beauty, they take the place of carriages in winter; and there too sleds of lighter build, and supporting a light platform or seat, are made for coasting—i.e. sliding down hills. Long sleds for this purpose, sometimes capable of carrying forty persons, have two pairs of runners with their framework, on which a platform rests (often like a ladder, covered with a cushion); the front pair of runners is turned on a pivot by a steersman with the aid of ropes and pulleys. In Canada toboggans are in popular use for coasting (here called tobogganing), and consist of a single length of wood (or two boards joined together), about ¼ inch thick, curved backward in front, and the curved portion held back by leather thongs. The toboggan of course has no runners, may accommodate two to eight persons, and is guided by the steersman's foot dragging behind, toe downward. In Russia sleighs are often drawn by a team of three horses (*troika*).

Sleswick (Danish *Slesvig;* Ger. *Schleswig*) forms, united with the former duchies of Holstein and Lauenburg, a province of Prussia, having the Baltic Sea and the territories of Lübeck and Mecklenburg for its eastern boundary, Hamburg and Hanover for its southern, the North Sea for its western, and Jutland (Denmark) for its northern. Area, 7273 sq. m. It belongs to the alluvial peninsula of Jutland, its eastern half being an undulating plain and its western a series of low-lying but very fertile marsh-lands, protected from the ocean by sea-banks. The eastern coast (230 miles) is deeply indented by several long narrow arms of the sea called fjords, some of which make excellent harbours, and alongside it lie the large islands of Fehmarn and Alsen. The western coast is more regular, but very low; and a string of low islands (Sylt, Föhr, Pellworm, Nordstrand, and others) and sandbanks stretching right in front of it protect it to some extent from the waves of the North Sea. The Elbe (on the southern border) and the Eider are the most important rivers; but the province is crossed by the North Sea and Baltic Canal (61 miles long), the Eider Canal (20), the Stecknitz Canal (35), and two or three shorter ones. The chief occupations of the people are agriculture, cattle-feeding, shipbuilding, and navigation. Corn and fat cattle are exported, the latter (of an excellent breed) in large numbers to England. Nearly 87 per cent. of the total area is under cultivation. Fishing is carried on in the inlets of the Baltic, and there are profitable oyster-beds amongst the sandbanks of the North Sea. Flensburg is the chief seaport. Pop. (1890) 1,217,393—i.e. for Sleswick and Holstein combined. Of this number nearly all belong to the Low German stock (except 140,000 Danes in the north), and are Protestants in religion. Sleswick-Holstein sends 10 members to the imperial parliament, and 19 to the Prussian house of representatives, and has an assembly of its own consisting of 58 members.

At the dawn of history Sleswick was inhabited by the Cimbri; they were succeeded by the Angles, Jutes, and Frisians. But the greater part of the Angles crossed over into England, and their place was taken by Danes. When Charlemagne reduced the Saxons to his sway the Danish king built a wall from sea to sea alongside the Eider, the southern frontier of his domains, to protect himself against the emperor's attacks. And from that time (808) for 350 years Sleswick alternated between the Danish and the imperial yoke, its duke paying homage sometimes to the king of the Danes, sometimes to the German emperor. In 1157 the duchy was definitively united with the Danish kingdom. Meanwhile Holstein to the south was conquered and christianised by Charlemagne and his successors, and the countship of Holstein formed in 934 by the German king Henry I. Between 1157 and 1225 this southern part of the peninsula was subject to the rule of Denmark. From the year 1386 the Danish duchy of Sleswick and the German countship of Holstein had one common ruler, the Count of Holstein having fallen heir to the former dignity in that year. About fifty years earlier a compact had been made, the *Constitutio Waldemariana*, by which it was solemnly agreed that the crown of Denmark and the duchy of Sleswick should not in future be held by the same individual ruler. In spite of this agreement, however, King Christian I. of Denmark possessed himself of both Sleswick and Holstein, and, having in 1474 acquired from the Emperor Frederick III. the suzerainty of Ditmarsh, he converted the countship of Holstein into a duchy. The sons of the next Danish king divided his territories amongst them after his decease, and their immediate successors still further subdivided them; but eventually they were all gathered up again (1581) under the heads of the royal line (Glückstadt) and the ducal line (Gottorp). The latter held Sleswick as a fief of Denmark and Holstein as a fief of the German empire; nevertheless the king of Denmark ruled in several detached portions of both duchies.

Ten years after the conclusion of the Thirty Years' War the Duke of Sleswick (Frederick III.), backed by his son-in-law Charles X. of Sweden, declared himself an independent and sovereign prince. This the Danish kings all along resented, and at length, when Charles XII. of Sweden was routed at Pultowa, Frederick IV. of Denmark grasped (1721) the opportunity, invaded Sleswick, expelled the duke, and seized his territories in that duchy. The heads of the ducal line became, one in 1751 king of Sweden, the other (the nominal duke) in 1762 emperor (Paul III.) of Russia, and soon ceased to take any interest in Sleswick-Holstein, the whole of which (both duchies) was formally given up to the king of Denmark in 1767. On the dissolution of the German empire in 1806 Holstein was united with the Danish crown, but was reincorporated in the German Confederation by the Congress of Vienna in 1815. From 1767 the Danish sovereigns had steadily endeavoured to make the duchies thoroughly Danish and to reduce them to complete dependence upon the Danish crown. At length in 1846 King Christian VIII. proclaimed that the law of succession in Sleswick should be the same as for the Danish crown—in other words, that Sleswick was to be made an integral part of the Danish kingdom. This action, as well as the refusal of the king to summon the common estates of the joint duchies, was warmly and actively resented by the people of Sleswick and by the German party in both Sleswick and Holstein. At length (March 1848) the latter, headed by Count Reventlow and Prince Frederick of Augustenburg, rose in revolt. They found a zealous supporter in Frederick William IV. of Prussia, who made himself the executive agent of the German Confederation. War began in March 1848; several severely contested battles, as at Düppel, were fought before peace was made in the end of 1850. Through the intervention of Austria matters were for a time put on a footing satisfactory to the people of the two duchies—so far at least as fair words and fine promises could go. The Danes, however, still pursued their policy of forcible denationalisation in both Holstein and Sleswick. The death of King Frederick VII. of Denmark in the end of 1863 brought the question of succession to a crisis; for Frederick of Augustenburg proclaimed himself Duke of Sleswick, to which title the new king of Denmark likewise laid claim. Austria and Prussia called upon Duke Frederick to abdicate and leave the duchy, and forbade Denmark to proclaim a constitution for it. Both refused to obey. Thereupon the two powers took up arms against the northern kingdom, and after a short but decisive campaign wrested both Holstein and Sleswick from the Danes. How they divided their conquest between them, and then quarrelled over the division, and how Austria came out of the conflict thoroughly worsted, has been already told under Germany (q.v., p. 183). Since the conclusion of that war (1866) Sleswick-Holstein has constituted a province of the kingdom of Prussia.

The *town* of Sleswick ranks as the capital of Sleswick-Holstein. It stands at the head of the Baltic inlet called the Schlei, 28 miles NW. of Kiel, and has a Gothic cathedral, rebuilt since a fire in 1440, and Gottorp Castle, the former residence of the dukes. Pop. (1885) 15,187. Sleswick was a noted trading-town in the 9th century, and was made a bishopric in the middle of the 10th.

Slickensides are the smooth, polished, or striated, and generally glazed surfaces of joints and faults (see DISLOCATION) in rocks. They are considered to have been produced by the friction of the two surfaces during the movement of the rock. The surface of slickensides is often coated with a deposition of calcite, hæmatite, chalcedony, or other mineral matter, which takes the form of the grooves and striæ, and thus often looks as if it had been striated.

Sliding Scale. See CORN LAWS.

Sligo, a maritime county of the province of Connaught, Ireland, is bounded on the N. by the Atlantic and the Bay of Donegal, S. by Roscommon and Mayo, E. by Roscommon and Leitrim, and W. by Mayo. It is 41 miles from E. to W., and 38 from N. to S.; the total area is 461,796 acres. Pop. (1841) 180,886; (1861) 124,845; (1881) 111,578; (1891) 98,338—a decrease of 11·9 per cent. About 91 per cent. are Roman Catholics. The coast-line is indented with bays, the largest being Killala Bay and the Bay of Sligo. The surface rises gradually from the coast as far as the Slieve Gamph and the Ox Mountains (1778 feet). Sligo contains some picturesque lakes, especially Lough Arrow and Lough Gill. The streams are inconsiderable; but three—the Moy, Owenmore, and Garvogue—are to some extent navigable. Iron is abundant and copper occurs, but neither is worked. The climate is moist, mild, and healthy. The soil is in part sandy loam, in part a deep rich loam. The chief occupation is agriculture; until some years back the people were chiefly engaged in tillage, but now they devote most attention to pasturage, especially the feeding of cattle. Close upon one-half of the total area is under grass; 27½ per cent. is uncultivable; and only about 80,000 acres are under crops, including some 19,000 acres of oats, 18,000 acres potatoes, and 32,000 acres of meadow-land. The bulk of the holdings range between 5 and 30 acres each. Coarse woollens and linens are manufactured. A considerable number of the population engage wholly or partially in fishing. The county forms two parliamentary divisions. The principal towns are Sligo, Ballina (1442; also 4318 in Mayo), Ballymote (1145), and Tobercurry (1081). Sligo was anciently the seat of the O'Connors. It contains a group of cromlechs near Sligo, a round tower at Drumcliffe, ruins of an ancient abbey at Ballysadare, and numerous other raths, cromlechs, and ancient caverns.

SLIGO, chief town of the county, stands at the mouth of the Garvogue, 137 miles NW. of Dublin by rail. Pop. (1861) 13,361; (1881) 10,808; (1891) 10,110. Sligo had its origin in a Dominican abbey, built in the middle of the 13th century by Maurice Fitzgerald, Earl of Kildare, and now in ruins, and was formerly surrounded with walls and defended by a castle (1242), of which no vestiges are now left. There are a Roman Catholic cathedral, a modern town-hall, a lunatic asylum, &c. The town has some trade, exporting cattle, corn, butter, and provisions. Steamers ply regularly between Sligo and Glasgow, Liverpool, and Londonderry. Sligo was besieged by the parliamentarians in 1641, and was captured and lost again by the adherents of William III. It formerly returned a member to parliament, but was disfranchised in 1870.

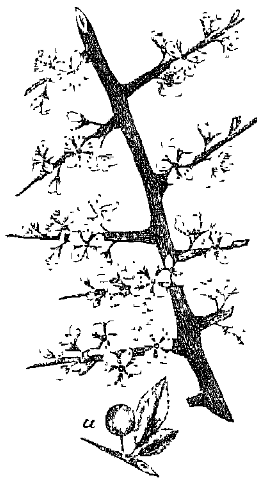
See county histories by T. O'Rorke (1889) and W. G. Wood-Martin (1890).

Sling, a weapon much in use before the introduction of firearms, consisted of a piece of leather, with a round hole in the middle and at each end a cord of about a yard in length. The slinger held the free ends of the cords in one hand, and whirling the weapon round and round with his utmost force in a vertical direction, suddenly let go one of the cords. This propelled the stone or other missile that was placed in the leather at a great speed forwards for a considerable distance. Slings fastened to the end of a short pole were capable of discharging a bolt with such force that at 500 yards distance it could pierce a helmet or a thin shield. The sling is not mentioned in the *Iliad*, but already in the Persian wars we find traces of its use. The Acharnians, and later the Achæans were the most skilful, but amongst all ancient races the Balearic islanders were counted the most expert; and the sling was a favourite weapon of several semi-savage peoples, notably the Tahitians in the Pacific. See W. Hawkins, *The Use of the Sling as a Warlike Weapon among the Ancients* (1847).

Slip, in a dockyard, is a smooth inclined plane, sloping down to the water, on which a ship is built. It requires a very solid foundation. For the repair of ships of comparatively moderate size slips were designed by Mr T. Morton, Leith, and consist of a carriage with blocks, as in a graving-dock, working on an inclined railway extending for some distance beyond high-water to a sufficient depth below low-water of spring tides to enable vessels to be floated on the carriage. When the vessel is floated over the cradle powerful hauling gear, worked by steam or other power, is set in motion to draw the ship out of the water. At the Tyne, for example, the slipway is 1000 feet in length, and a hundred vessels yearly are repaired on it. Slipways are useful adjuncts to shipping ports, and for vessels up to 2500 tons register they are better than a dry-dock, as better light is afforded for making repairs, and no pumping is needed; but this size is nearly the limit, though there is no good reason, if the slip and gearing be made strong enough, why larger vessels may not use slipways. See DOCK, SHIPBUILDING.

Sliven (Turk. *Islimia*), or SELIMNIA, a town of East Roumelia, at the southern base of the Balkan Mountains, 70 miles N. by E. of Adrianople, is celebrated for its annual fair. Arms, cloth, and attar of roses are manufactured. Pop. (1888) 20,893.

Sloane, SIR HANS, physician and naturalist, was born at Killyleagh, County Down, 16th April 1660, the son of an Ulster Scot. He devoted himself to natural history and medicine, and in spite of an attack of hæmoptysis, which lasted from his sixteenth till his nineteenth year, he arrived in London in 1679 a well-read student. His apprenticeship to Stafforth, a pupil of Stahl, and his friendship with Boyle and Ray did much to encourage and advance him in his favourite studies. In France he attended the lectures of Tournefort and Duverney, and obtained on his return, by the active support of Sydenham, a footing in London as a physician. Already F.R.S., he spent over a year (1685-86) in Jamaica, collecting a herbarium of 800 species; and after his return became physician to Christ's Hospital (1694-1724), President of the College of Physicians (1719-35), Secretary to the Royal Society (1693), Foreign Associate of the French Academy (1708), and Sir Isaac Newton's successor as President of the Royal Society (1727). He had been created a baronet and physician-general to the army in 1716, and in 1727 was appointed royal physician. Though of remarkably delicate constitution, he lived to the great age of ninety-two, dying at Chelsea, 11th January 1753. His museum and library of 50,000 volumes and 3560 MSS., offered at his death to the nation for £20,000, formed the commencement of the British Museum (q.v.). He contributed numerous memoirs to the *Philosophical Transactions*, and published in 1745 a treatise on medicine for the eyes. But his great work was the *Natural History of Jamaica* (fol. 1707-25).



Sloe (*Prunus spinosa*): *a*, fruit.

Sloe, or BLACKTHORN (*Prunus spinosa*), a shrub of the same genus with the plum, and perhaps really of the same species with it and the bullace. It is generally a shrub of 4 to 10 feet high, but sometimes becomes a small tree of 15 to 20 feet. It is much branched, and the branches terminate in spines. The youngest shoots are covered with a fine down. The flowers are small, snow-white, and generally appear before the leaves. The fruit is ovate, or almost globose, pale blue with blackish bloom, and generally about the size of the largest peas. The sloe is abundant in thickets and borders of woods and hedgerows everywhere in Britain and almost all parts of Europe. The shoots make beautiful walking-sticks. Being spiny, the sloe is sometimes planted as a fence against cattle; but the roots having a habit of spreading and sending up suckers, hedges of it are troublesome to keep from encroaching on the fields. The bark is bitter, astringent, and tonic. The flowers, with the calyx, are purgative, and were once a favourite domestic medicine. The leaves are used for adulterating tea. The unripe fruit dyes black. The fruit, which is very austere, may be made into a preserve; and from it a kind of brandy may be extracted. An astringent extract of it, called *German Acacia*, was once much employed in cases of diarrhœa. The juice has been used to impart roughness to port wine and in the fabrication of spurious port. The sloe of the southern United States (*P. umbellata*) has a pleasant black or red fruit.

Slonim, a town of Russia, 75 miles SE. of Grodno. Pop. 22,275.

Sloop is a one-masted cutter-rigged vessel, differing from a Cutter (q.v.), according to old authorities, in having a fixed bowsprit and somewhat smaller sails in proportion to the hull. The terms 'sloop' and 'cutter' appear, however, to be used nearly indiscriminately. In the British navy a sloop-of-war was a vessel, of whatever rig, between a corvette and a gun-vessel, and ordinarily constituting the command of a commander. In the days of the sailing navy sloops-of-war carried from ten to eighteen guns; but since the introduction of steam the number of guns has ceased to be distinctive. Under the new classification of the navy, which was made in 1888, the term sloop-of-war has been modified, many modern vessels which formerly would have been designated as sloops being now known as third-class cruisers. The few sloops-of-war still found on the *Navy List* are all more or less obsolete, and it is doubtful if any more will be built.

Sloth. These animals, which are referable to two genera (*Cholœpus* and *Bradypus*), form a distinct family of the order Edentata. Their nearest allies are the armadillos and ant-eaters of South and Central America, to which countries the sloths also are restricted. They are exclusively arboreal animals and entirely vegetable feeders. In the forests which they inhabit it is quite unnecessary for them to descend to the ground in order to reach another tree, as the interlocking of the branches affords an easy passage. It has been asserted that when a sloth is absolutely compelled to walk upon the ground it acquits itself more creditably than might have been expected from an animal so conspicuously fitted for a purely arboreal life; though some authorities allege that it is quite incapable of progression upon the ground. The form of the animal is bulky and awkward; the fingers and toes are long, and furnished with long curved claws, which enable it to obtain and keep a firm hold upon the branches along which it crawls with the body hanging down. The two genera *Cholœpus* and *Bradypus* are known respectively as the 'two-toed' and 'three-toed' sloths, from the number of toes upon the fore-feet. Neither genus has any incisor teeth; they have canines and molars with flat crowns, suitable for crushing vegetable food. The hair of the sloth is coarse and shaggy, and frequently of a dirty green colour: this colour is lost in captivity. It has been shown by Mr Sorby to be due not to any colouring substance in the hair, but to the presence of minute green plants (Algæ). The damp and warmth of the tropical forests probably favours the growth of these Algæ, which disappear when the conditions are altered on the removal of the creature from its native forests. The long green hair combined with the lethargic habits of the sloth must be a protection to it against the attacks of jaguars and large snakes, which are its principal foes. This resemblance to a lichen-covered branch is strangely heightened in one species by an oval mark upon the back which bears the closest resemblance to the broken end of a branch. When the sloth is driven to take extreme measures it can use its teeth and claws to good purpose, and it has been even known to grasp a dog round the neck and strangle it.

Two-toed Sloth (*Cholœpus didactylus*).

Sloth Bear. See BEAR.

Slough. See SKIN-CASTING, and SNAKES, p. 530.

Slough, a town of Buckinghamshire, 18½ miles W. of London and 2½ NNE. of Windsor. It has grown from a mere village since the railway epoch, and is a well-built place, the seat since 1863 of the British Orphan Asylum; but it will always be chiefly remembered as the home of Sir William Herschel from 1786 till his death, and thereafter till 1840 of his son, Sir John. Stoke Poges and the Burnham Beeches, both noticed separately, are near. Pop. (1861) 3425; (1891) 5427. See Phipps's *History of Upton-cum-Chalvey* (Slough, 1886), the parish in which Slough is chiefly situated.

Slovaks, a branch of the Slavs (q.v.), who dwell in the mountainous districts of north-west Hungary, and number in all about 2,000,000. They are a race of peasants, and live by cultivating the soil. In religion they are partly Lutherans, partly Roman Catholics. These people formed a constituent part of the ancient kingdom of Moravia, but have been incorporated among the subject-lands of the Hungarian crown since the beginning of the 11th century. Their language is little more than a dialect of Czech, the speech of the Bohemians. Down to the end of the 18th century the Slovaks used Czech as their written or book language, but since that period certain patriotic writers—more notably the poets Holly, Chalupka, and Sladkovitch, the philologists Bernolak and Hattala, and the novelist Tomaschik—have tried to create a pure written Slovak literature. Their efforts have met, however, with considerable opposition from both the Hungarians and the Bohemians.

Slovenians, a branch of the south Slavonic stock to which also the Serbs (Servians) and Croats belong. The Slovenians are found mainly in Styria, Carinthia, Carniola, and adjoining parts of Hungary, and number in all about 1,250,000. They are sometimes called *Winds* or *Wends*, though distinct from the Wends (q.v.) of north and east Germany. They have been subject to the House of Hapsburg since the 8th century. There is not much literature in the native speech apart from the 'Freising Fragments' (forms of confession and a sermon), dating from the 10th century, and 16th-century translations of the Bible, until we come to the end of the 18th century. Since the revival of the language which then took place the principal writers have been the poet-philologist Vodnik (1758–1819), the poets Preseren (1800–49) and Vesel-Koseski, the journalists Bleiweiss and Janezic. See SLAVS.

Slow-match, generally rope steeped in a solution of saltpetre and lime-water, and burning at the rate of one foot per hour. Port-fires are very similar, but burn an inch a minute. They were used for firing guns before the introduction of friction tubes, and sometimes for firing military mines, &c. They have been superseded by *Bickford's fuze*, a train of gunpowder enclosed in two coatings of jute thread waterproofed. There are two kinds, the *ordinary* (a slow match), burning at the rate of 3 or 4 inches a minute, and the *instantaneous* (a quick match), burning at the rate of 30 yards per second, and distinguished from the former by yellow threads crossed on the outside.

Sloyd (Swed. *slojd;* cf. Eng. *sleight*) is the name given to a certain system of manual instruction which obtains in the schools of Finland and Sweden, and which has been largely adopted in other countries. The word properly denotes work of an artisan kind practised not as a trade or means of livelihood, but in the intervals of other employment. The fundamental idea of the educational sloyd is to utilise this sloyd-work in the schools in a disciplinary way as an integral part of general education. To this end the older children, generally boys, are engaged for a certain number of hours a week in making articles of common household use varying from simple objects such as a flower-stick or a pen-rest to more complicated articles such as a cabinet or a small table. These objects are made from drawings or from models, but to exact measurements, and the utmost accuracy and finish are insisted upon. The tools employed are the ordinary tools of the carpenter, with certain exceptions, the most important of which is the knife. It is held that work of this kind is valuable, as supplementing and correcting the ordinary school education in the three R's. It fulfils the injunction 'to put the whole boy to school,' it develops faculties that are not otherwise exercised, it trains the eye, and in particular gives a general dexterity of hand which has a direct economical value, particularly in countries such as Finland and Sweden, where the sparseness of the population does not allow of much subdivision of labour. But valuable as are these practical results, the advocates of sloyd maintain that they are only of secondary importance. It is held that in making the models certain educational results, valuable generally, are obtained, which do not follow in like measure on the teaching of the ordinary school subjects, and that, therefore, work of this kind is beneficial for all pupils whatever their future occupation may be. It utilises, as a means of education, the universal delight of children in making things, and in addition to its special function of training the hand and eye it develops in a pre-eminent degree habits of self-reliance, order, accuracy, attention, and industry. It tends like gymnastics to the increase of physical strength, and it has a desirable effect socially, inasmuch as it fosters a liking for bodily labour and a respect for it. Above all it stimulates and exercises the practical intelligence or power of thought in dealing with things. To obtain these results the educational ends of sloyd must be kept prominently in view. The teacher accordingly ought to be a trained teacher who has acquired the requisite manual skill rather than an artisan, and the work ought to be properly graduated, regard being had to the greater or less difficulty of the exercises with tools involved in making each of the models. Besides wood-sloyd, sloyd-work in iron and in cardboard (*papp-slojd*) is also practised. There are also various systems of wood-sloyd differing in practical details. The main principles of sloyd had been advocated by many prominent educationists, and in particular by Herbart and by Froebel, of whose kindergarten system sloyd may be regarded as a continuation. But it was in Finland, on the reorganisation of the national system of education by Uno Cygnæus, that manual work was first made a part of the regular instruction in the common schools. In Sweden this branch of education has been systematised and its principles expounded, chiefly by Herr Otto Salomon, director of the great slojd-seminarium at Naas (instituted 1872), where every year large numbers of students from all parts of the world receive gratuitous instruction.

Salomon's *Teachers' Handbook of Slojd* was translated and adapted for English teachers in 1891 by Mary R. Walker and W. Nelson, who also translated Alfred Johansson's *Practical Directions* (1892).

Slug, a name used for those land-molluscs of the order *Pulmonata* ('air-breathing') in which the shell is rudimentary or absent. They have the same structure as the Snails (q.v.), but the shell, when present, is usually concealed beneath the mantle, though in some genera (e.g. Urocyclus) it is visible through an aperture in the mantle, while in others (e.g. Helicarion) it becomes decidedly spiral and more exposed, so that it is impossible to draw any hard and fast line between the true slugs and the shell-bearing pulmonates or snails. The mantle is usually an oval structure placed anteriorly on the back, with an orifice on its right side leading to the pulmonary cavity. In Arion and some other genera there is a gland at the posterior extremity of the body for the secretion of mucus or slime. Slugs are divided into six families, each of which seems to have been evolved separately from a group of shell-bearing ancestors. The family Succineidæ, in which the jaw has a quadrate accessory plate, contains both testaceous and shell-less genera, the latter being found in South America, the West Indies, and the Indian and Australian regions. The Vaginulidæ, in which the male and female genital orifices are distinct, occur throughout the tropical regions of the world. The Limacidæ, including the genera Limax and Agriolimax, are a family of almost world-wide distribution, known by the possession of a smooth jaw and aculeate marginal teeth. The Arionidæ, the typical genus of which is Arion, have a usually ribbed jaw and quadrate marginal teeth; they are found most abundantly in Europe and North America, more sparingly in South America, Asia, and Africa, and not at all in Australia. The Testacellidæ (including Testacella) and the Selenitidæ, both of wide distribution, have all the teeth aculeate; the former are without, the latter with, a jaw. Over 500 species of slugs have been described, of which nineteen inhabit the British islands. Of these three belong to Testacella, a genus possessing a small external shell on the posterior part of the body. The Testacellæ are carnivorous, and devour earthworms, which they pursue underground. Four species belong to Limax—viz. the Great Gray Slug (*L. maximus*) and its ally *L. cinereoniger*, the Yellow or Cellar Slug (*L. flavus*), recognised by its yellowish colour and bluish tentacles, and the Tree Slug (*L. arborum*). Two species belong to Agriolimax, the common Gray Slug of our gardens (*A. agrestis*) and the Brown or Marsh Slug (*A. lævis*), which is found in damp places. Two are of the genus *Amalia*, which differs from Limax in having the

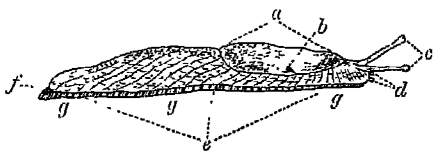


Fig. 1.—Diagram of a Slug:
a, mantle; *b*, respiratory orifice; *c*, eye-peduncles; *d*, tentacles; *e*, sole; *f*, mucus-pore; *g*, foot-fringe.

back sharply keeled. There are several of the genus Arion, differing from Limax in the more anterior position of the respiratory orifice, and the possession of a caudal slime-gland. The Black Slug (*A. ater* or *empiricorum*) is a very large species, varying much in colour, being black, white, black with white sides, black with a red fringe, brown, brown with yellow sides, red, gray, or yellow. The red variety is called the Red Slug, and was considered by Linnæus a distinct species.

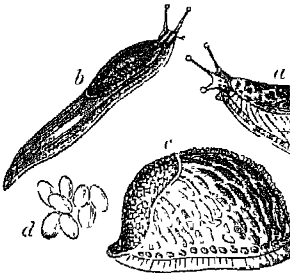

Fig. 2.—Slugs:
a, *Agriolimax agrestis*; *b*, *Arion*; *c*, *Arion empiricorum*, at rest; *d*, its eggs.

The Striped Garden Slug (*A. hortensis*) is a small species common in gardens; it has the under side of the foot yellow or orange. The Irish Slug (*Geomalacus maculosus*) is only found in County Kerry, Ireland, and in Portugal. Slugs do great damage to garden crops, and various methods have been devised for destroying them. They may be sought under stones or boards, or enticed by decaying cabbage-leaves, or collected while on the move at night, or in wet weather. They are readily killed by salt water. They lay their eggs, which often resemble small oval bags of jelly, in clusters in moist places. Slugs frequently climb trees, and some of them, especially the Tree Slug, have the power of descending by means of threads of mucus. The name Slug is often applied by gardeners to the larvæ of saw-flies (Tenthredinidæ).

Slutsk, a town or large agricultural village of Russia, 60 miles S. of Minsk. Pop. 19,208.

Sluys, a town of Holland, province Zealand, on a bay of the North Sea, 6 miles NE. of Bruges. In the middle ages it was a seaport of some importance, but it is most celebrated for the naval battle fought off the shore between the English and the French on 24th June 1340, in which Edward III. won a complete victory. Pop. 2631.

Smack, a generic term for small decked or half-decked coasters and fishing-vessels. Most smacks are rigged as cutters, sloops, or yawls.

Smalcald. See SCHMALKALDEN.

Small-arms include all weapons that can be actually carried by a man. They are described under their respective heads, BAYONET, FIREARMS, PISTOL, REVOLVER, SPEAR (or Lance), RIFLE, SWORD. Small-arms are manufactured for the British government at Enfield and Birmingham.

Small Debts is a phrase current in Scotland to denote debts under £12, recoverable in the Sheriff Court (see SHERIFF). In England the same debts are recoverable in the County Court (q.v.). See DEBT, Vol. III. p. 718.

Small Holdings. See ALLOTMENTS, PEASANT PROPRIETORSHIP.

Smallpox, or VARIOLA, is one of the most formidable of the class of febrile diseases known as the *Exanthemata* (q.v.). The period of incubation (see under MEASLES) is generally twelve days. All cases of regular smallpox are divisible into three stages—viz. (1) that of the initial or eruptive fever; (2) that of the progress and maturation of the specific eruption; and (3) that of the decline. The course of an ordinary case of *discrete* smallpox—i.e. one where the pocks remain throughout distinct from each other—will first be described, and afterwards the other forms will be discussed. The *first stage* begins with rigors, followed by heat and dryness of the skin, a quickened pulse, furred tongue, loss of appetite, pain in the pit of the stomach, with nausea, vomiting, headache, and often pains in the back and limbs. The violence of the pains in the back, and the obstinacy of the vomiting, are frequently very well marked and characteristic symptoms. In children the disease is often ushered in by convulsions; while delirium sometimes attends its outset in adults. On the third day minute red specks begin to come out—first on the face (where they are always most numerous), then on the neck and wrists, and on the trunk of the body, and lastly, on the lower extremities. These correspond to the incipient *pocks*, which can be felt like small shot under the skin, better, sometimes, than they can be seen. The fever, pain, sickness, &c. usually begin to subside as soon as the eruption appears, and by the beginning of the fifth day, when the eruption is generally fully out, and the *second stage* commences, have entirely disappeared. Upon the second or third day of the eruption a little clear lymph is seen in each pimple, which has increased considerably in size since its first appearance, and which is thus converted into a *vesicle*. The vesicles gradually increase in breadth, and, their contents becoming more and more yellow and opaque, are converted into *pustules*. These are at first depressed in the centre, but at their fullest development often become turgid and hemispherical. The suppuration on the face is complete by about the ninth or tenth day from the commencement of the fever, and the same process rapidly follows in the other parts of the body in the same order of succession as that in which the eruption originally appeared. The progress of the pustules is usually accompanied by swelling of the skin of the face, with a painful sensation of heat and tension; the scalp is often swollen; soreness of the mouth from a modified eruption there is often present; and the patient exhales a peculiar and disagreeable odour. About the eighth or ninth day of the disease a recurrence of the fever, known as the *fever of maturation*, or *secondary fever*, sets in, with a return of headache, restlessness, and sometimes delirium. The *third* or *declining stage* is little more than a period of convalescence. About the eleventh or twelfth day the pustules on the face become brown and dry at the top, or some of them break, and the fluid which oozes out solidifies into a yellowing crust; and from this time the process of *desiccation* goes on, the swelling of the face subsides, and at last only dry scabs remain, which gradually fall off about the fifteenth or sixteenth day. It is not till three or four days after the scabs have formed on the face that the same process is completed over the whole body. The scabs are usually completely gone by the twenty-first day, leaving behind them blotches of a reddish-brown colour, which sometimes continue for some months before they quite disappear; and some of the pustules, in consequence of ulceration of the true skin, may leave pits, especially on the face, which remain permanently. The period of scabbing is accompanied by various symptoms of improvement: the tongue becomes clean, the appetite returns, and by the time that the scabs have fallen off the patient may be regarded as restored to health; so that the entire course of a case of discrete smallpox occupies about three weeks.

Generally speaking, the severity of the disease is proportional to the number of pocks; and when these are so numerous as to run together on any part of the body, the disease is said to be *confluent*. This form differs in many important respects from that already described. The eruption is necessarily modified: the individual pocks are smaller, but by their coalescence they give the skin of the face an appearance 'like a mask of parchment,' and generally lead to much more scarring of the skin. Severe laryngitis and bronchitis, and ulceration of the corneæ, with consequent impairment or destruction of sight, are of frequent occurrence; and salivation is a usual symptom. But most important of all is the difference in the course of the fever. The remission described above in the first stage is slight, if it occurs at all; and the secondary fever, although on this account less conspicuous, is more severe, and much more dangerous to life.

Malignant smallpox is characterised by the severity of the onset, but particularly by the occurrence during the first few days of hæmorrhages under the skin, and from the various orifices of the body. Such cases are almost without exception rapidly fatal, sometimes so early that no sign of the characteristic eruption appears at all.

Modified smallpox, sometimes (but not happily) called *varioloid*, is the name applied to cases of the disease in which the eruption runs a less severe course than usual. They may be at first discrete or confluent; but the pocks abort either at the papular or the vesicular stage, or if they become pustular are small, and dry up with unusual rapidity. The constitutional symptoms are correspondingly less marked. This form of the disease with rare exceptions occurs only in those who have been vaccinated, or have had a previous attack of smallpox. The form of the disease which follows Inoculation (q.v.) has a shorter incubation period (usually ten days), and a shorter and milder course; and the mortality is very much less than when it is contracted by infection.

The *cause* of smallpox is universally allowed to be a specific contagion, of whose nature we are in the most profound ignorance. There is probably no disease so contagious as this. Dr Haygarth stated (in 1793) that, during his long attention to this subject, not a single instance had occurred to prove that persons liable to smallpox could associate in the same chamber with a patient in the distemper without receiving the infection. The contagion acts either through the air, or by contact with the skin, or by inoculation; and the disease may be caused by the dead body, even when it has not been touched. What products of the diseased body are contagious is not exactly known, but the contents of the pustules and the dried scabs certainly are so. Opinions are divided as to the period at which the disease begins and ceases to be contagious. It is safest to maintain that it is capable of self-propagation as soon as the febrile symptoms have exhibited themselves. How soon the patient ceases to be dangerous cannot be decided with accuracy; but the stability of the contagious principle may be inferred from the fact that clothing will retain it for months, and it is said for years, when confined. Like all the contagious exanthemata, smallpox appears in an epidemic form, at irregular and, in our ignorance, it would almost seem capricious intervals. After an extraordinary exemption, perhaps for years, a district is suddenly invaded by it, and continues to suffer for a longer or shorter period, after which the disease spontaneously disappears—dies out, as it were—and does not reappear perhaps for years. Different epidemics vary very much in their severity, and isolated cases are usually milder than those occurring when the disease is epidemic. Race has much to do with the severity of the disease; the constitution of the dark races, especially the Negro, being singularly susceptible of the contagion, and exhibiting very little power of resisting the fatal tendency of the disease.

It is generally admitted that the discovery of *Vaccination* (q.v.), by which smallpox is deprived of its danger, is the greatest triumph of modern medicine. *Inoculation* (q.v.) protected the individual, but, by spreading the disease, increased rather than diminished the total number of deaths, while vaccination has the advantage of protecting both the individual and the community.

With regard to prognosis, it may be stated generally, it is a very fatal, and was formerly an extremely destructive disease—one death occurring in every four or five cases. Modified smallpox is very seldom fatal, although instances of death are occasionally reported. Smallpox is more fatal at the two extremes of life than in the intervening period, and is especially dangerous in pregnancy. In olden times it was believed that the eruption was an effort of nature to get rid of the noxious matter, and hence heating and stimulating measures were adopted with the view of promoting the eruption. To Sydenham belongs the credit of first recommending an entirely opposite or cooling mode of treatment; but his suggestions met with the most strenuous opposition, and it was not till long after his death that the cooling treatment was fairly established. In mild cases, and in cases of modified smallpox, the physician has merely to guard the patient against hurtful influences, such as stimulating foods or drinks, too hot a room, or improper exposure to cold, and to prescribe cooling drinks during the fever, and occasional laxatives if they shall be required. In more severe cases the fever may be combated by saline purgatives, prescribed so as to produce two or three liquid stools daily, and by free ventilation of the surface of the body. When the eruption is all out, if the pimples on the face are few and distinct the danger may be regarded as over, and no further treatment is required. If, however, the disease assume a confluent form, wakefulness and restlessness are apt to come on about the eighth day, and opiates in free doses may be prescribed with benefit. If the pustules are abnormally torpid in reaching their maturity, it may be expedient to administer strong broths, or even wine; and when the pustules are livid, and intermixed with Petechiæ (q.v.), bark and acids must be additionally ordered, although the patient is then too often beyond the reach of help. During the secondary fever the bowels must be kept gently open, and opiates should be prescribed once or twice each day. A more nourishing diet is now called for, and wine should be given if the pulse is very weak. The external itching is partly relieved by the opiates, but local applications are also employed: cold cream, or a mixture of equal parts of olive-oil and lime-water, may be thus used with advantage. Numerous special methods have been devised for the purpose of preventing the pitting or seaming of the face, which is often a hideous permanent disfigurement to the patient, but there is not yet sufficient evidence that any of them is uniformly satisfactory in its results.

During the period of desquamation an occasional warm bath may be prescribed with advantage; and the patient should always resort to this measure, as a precaution against carrying the contagion about with him, before again mixing in society.

The history of this remarkable disease is clothed in considerable obscurity. Its original habitat is quite uncertain; but there seems no doubt that it has been prevalent in India from a remote period, and in China since at least 200 years before the

Christian era. It has been conjectured that it was one of the pestilences which occurred in Europe during the first and second centuries after that era; but the first accurate description of it is that of Rhazes, an Arabian physician, who flourished early in the 10th century. It appears to have reached England towards the close of the 9th century. After the Crusades it prevailed in most of the temperate countries of Europe, but did not reach the northern countries of Norway, Lapland, &c. for some time later. In 1517 it was carried from Europe to St Domingo; and three years later it reached Mexico, where it committed fearful devastations, and whence it spread with intense virulence throughout the New World. (According to Robertson, three millions and a half of people were destroyed in Mexico alone.) In 1707 it was introduced into Iceland, when more than a fourth part of the whole population fell victims to it; and it reached Greenland still later (1733), when it spread so fatally as almost to depopulate the country. These cases are striking illustrations of the law that seems universally true, that a contagious disease is always most virulent on its first introduction to a new scene of action. At the present day the interior of Africa, and especially the upper basin of the Nile, seems to be the region where smallpox is most destructive. In Europe it is constantly present in most of the large cities; but during the 19th century—i.e. since the introduction of vaccination—epidemics have been much less frequent and severe than before. The most intense and wide-spread was that of 1869–73 (see Report of Medical Officer of the Privy-council, 1874). Smallpox seems first to have been called by that name in the 15th century; *pockes* or *pox* (a contracted plural of pock) having come to be loosely used for several eruptive diseases, and especially for 'French pox' or syphilis. Till Sydenham's time measles and scarlet fever were frequently confounded with smallpox.

SMALLPOX IN SHEEP (*Variola ovina*), although resembling the smallpox of men, is a distinct disease, not communicable either by contagion or inoculation to men or children, or even to dogs or goats. It prevailed as an epizootic in England in 1277, was well known for more than 200 years previous to that date, but in more modern times it did not invade the country until 1847, when it broke out in a farm near Windsor, and quickly spread throughout Norfolk and the eastern counties, and in the summer of 1862 in Wiltshire, near Devizes. It is common on the continent of Europe. Variolous sheep or infected skins appear in both cases to have imported the disease from abroad. About ten days after exposure to contagion the infected sheep become feverish, have a muco-purulent nasal discharge, and a hot tender skin. The red pimples which first appear in about three days become white, and afterwards leave scabs or ulcers. The weakness is great, and the mortality varies from 25 to 90 per cent. Good food and nursing are the appropriate remedies. Promptly and carefully must the sick be separated from the sound; but if the spread of the disorder be not thus immediately checked the whole of the sound flock should be inoculated. The disease thus artificially produced appears in ten days, runs a mild course, occasions a loss of from two to five per cent., and in three weeks the disorder is got rid of and all risk of contagion over.

Smaragdite, a peculiar variety of Amphibole (q.v.), light grass-green in colour, with a foliated, lamellar, or fibrous structure. It occurs as a constituent of the rock called Eklogite.

Smart, CHRISTOPHER, a hapless English poet, was born at Shipbourne in Kent, April 11, 1722, and was educated at Maidstone, Durham, and Pembroke Hall, Cambridge, of which he was elected fellow in 1745. He won the Seatonian prize for an English poem on the attributes of the Supreme Being five times, and left college on his marriage to a step-daughter of John Newbery's in 1752. He now became a bookseller's hack, and made for some years a hard living betwixt improvidence, dissipation, and the expense of wife and children. His mind at last gave way, yet he lived on, with a few brief intervals of sanity, till his death in the rules of the King's Bench, 18th May 1770 or 1771. Smart was assisted by Samuel Johnson in his monthly publication, *The Universal Visitor*, and the moralist preserved a kindly feeling for him in his misfortunes. 'I did not think he ought to be shut up,' he said to Burney. 'His infirmities were not noxious to society. He insisted on people praying with him; and I'd as lief pray with Kit Smart as any one else. Another charge was that he did not love clean linen: and I have no passion for it.'

Smart's works include a number of feeble epigrams, birthday odes, and occasional poems; the *Hilliad*— a heavy satire in answer to a criticism of [Sir] John Hill's; a bald prose translation of Horace (1756), well known to schoolboys; a poor poetical translation of *Phædrus* (1765), and a still poorer metrical version of the *Psalms* (1765), of the *Parables* (1768). His poems were collected in 1791, but the editor was careful to exclude the only thing that now claims a notice, *A Song to David* (first printed in 1763), some of the stanzas of which are said to have been scratched with a key on the walls of his madhouse. The poem extends to a hundred stanzas, and is marred by repetitions, and grievous defects of rhythm and structure, but it shows a genuine spark of true poetic inspiration not common in its age, and it is not too much to say that the poor poet here for once 'had reached the zenith from his madhouse cell.' Rossetti called it 'the only great *accomplished* poem of the last century . . . A masterpiece of rich imagery, exhaustive resources, and reverberent sound;' but the praise is extravagant. Smart is one of the figures with whom Browning holds his *Parleyings*, and supplies a chapter to Mr Gosse in his *Gossip in a Library* (1892).

Smart, HENRY, composer (nephew of Sir G. T. Smart, 1776–1867, organist to the Chapel Royal), was born in 1813 and educated for the law. But in 1831 he became an organist, and as such was soon famous. As a composer he possessed a true vein of melody, and a symmetrical and elegant style, his church music (e.g. *Ave Maria*) and his part songs (e.g. *Lady, rise*) being his best-known works. An opera, *The Gnome of Hartzburg*; a secular cantata, *The Bride of Dunkerron* (1864); and a sacred cantata, *Jacob*, were his most ambitious compositions. He died 6th July 1879, not having survived to enjoy a civil list pension of £100 that had been granted to him. A Life by Dr Sparks was published in 1880.

Smartweed, a name given to some of the Milkworts (q.v.) on account of their acrid properties; especially the *Polygonum Hydropiper*, or Water-pepper.

Smeaton, JOHN, an eminent civil engineer, was born at Austhorp near Leeds, 8th June 1724, and early showed a bent towards mechanical pursuits. On leaving school, where he excelled in geometry and arithmetic, he entered his father's office as law clerk; but his heart was not in his work, and about 1750 he removed to London, to commence business as a mathematical instrument maker. In the following year his experiments in mechanical invention were resumed. His improvements on mill-work gained him the

Copley Medal of the Royal Society in 1759. In 1753 he was chosen a member of the Royal Society; and in the following year he visited the Netherlands, and inspected the engineering works of that country. In 1755 the second wooden lighthouse on Eddystone (q.v.) rock was destroyed by fire, and the re-erection of the work was entrusted to Smeaton. The new lighthouse was built of stone (1756-59), and this great work, the greatest of its kind hitherto undertaken, remained for 120 years a stable monument of Smeaton's engineering skill, till the erection of the new Eddystone close by (1879-82). Even after his great achievement Smeaton seems to have had little employment, as he applied for and obtained in 1764 the post of 'receiver of the Derwentwater estate;' and this situation he held till 1777, by which time he was in full professional employment. The chief of his other engineering works were Ramsgate harbour (1774); the Forth and Clyde Canal; several important bridges in Scotland (Perth, Banff, Coldstream), together with an immense amount of mill-machinery. He also improved Newcomen's steam-engine. He was in constant attendance in parliament during a large portion of his life. In 1783 his health began to decline, and he retired from active business, dying at Austhorp of paralysis, 28th October 1792. In 1781 Smeaton wrote a *Narrative of the Construction of the Eddystone Lighthouse.* The Society of Civil Engineers published posthumously his numerous professional Reports (3 vols. 1797), which were regarded by his successors 'as a mine of wealth for the sound principles which they unfold, and the able practice they exemplify.'

See a *Short Narrative of John Smeaton* (1793); and Smiles's *Lives of the Engineers* (vol. ii.; new ed. 1874).

Smectymnuus, a name compounded of the initials of the following five divines: Stephen Marshall, Edmund Calamy, Thomas Young, Matthew Newcomen, and William Spurstow, joint-authors of *An Answer* (1641) to Bishop Hall's *Humble Remonstrance to the High Court of Parliament* (1641), in defence of the liturgy and episcopal government. Of the five authors, the chief was Thomas Young, Milton's tutor.

Smedley, FRANCIS EDWARD, novelist, was born in 1818 at Marlowe. Always deformed, he took early to writing, his half-dozen works including *Frank Fairleigh* (1850), *Lewis Arundel* (1852), and *Harry Coverdale's Courtship* (1854). Bright cheery books, these appeared originally in *Sharpe's Magazine*, of which Smedley for a time was editor, and they were illustrated by Cruikshank and 'Phiz.' He died in London, 1st May 1864.

Smeinogorsk. See ZMEINOGORSK.

Smell. See NOSE, SENSATION.

Smelling Salts. See SALTS.

Smelt (*Osmerus*), a genus of the Salmon family (Salmonidæ), characterised by the strong fang-like teeth, especially on the tongue and on the tip of the vomer, and by the rather large scales, which readily fall off. The Common Smelt (*O. eperlanus*), called *Spirling* or *Sparling* in Scotland, and *Eperlan* in France, is a fish of 8 or 10 inches (rarely 12 inches) in length. The form is very trout-like, but rather more slender; the tail is larger in proportion, and more forked. The lower jaw is longer than the upper. The back is whitish, tinged with green; the upper part of the sides shows bluish tints, the lower part of the sides and the belly are of a bright silvery colour. The smelt has a peculiar, cucumber-like smell, and a delicious flavour, on account of which it is highly esteemed for the table. From the sea smelts often ascend estuaries and rivers, and they thrive well in lakes and ponds. The same is true of the common American species—*O. mordax*. A third species—*O. thaleichthys*—of smaller size occurs on the Pacific coasts of North America, and another—*O. dentex*—on the corresponding Asiatic coasts. The name smelt is sometimes extended to related genera—e.g. Argentina, Retropinna, and the Pacific surf-smelts (Hypomesus).

Smelting. See COPPER, IRON, &c.

Smeru, or SEMIRU, the highest mountain of Java near the eastern end of the island. It is 12,240 feet high, and is an active volcano.

Smerwick, a peninsula and bay in County Kerry, Ireland, where in July 1579 Sir James Fitzmaurice landed, by authority of the pope, with a number of Italian and Spanish soldiers. They entrenched themselves within a fort, but in November were overpowered and put to the sword, to the number of six hundred, by Lord-deputy Grey and young Walter Raleigh. This gruesome story is introduced into Kingsley's *Westward Ho!*

Smew (*Mergellus albellus*), a bird of the family Anatidæ, in the same genus as the goosander and mergansers. Young birds and females—known as Red-headed Smews—are not uncommon in winter on the eastern coasts of Britain, but the males are more rarely seen. The smew is at home and breeds in northern Russia and Siberia, but has a wide range of migration.

Smilaceæ, a tribe of the natural order Liliaceæ, formerly by Lindley and others regarded as a distinct order under that name, and ranked by Lindley in his class Dictyogens (q.v.), and consisting of herbaceous or half-shrubby plants, generally more or less climbing, with reticulated leaves, and bisexual or polygamous flowers, a six-parted perianth, six stamens, a free three-celled ovary, with cells one or many seeded, three stigmas, and a roundish berry. The typical genus (Smilax) is, from an economical point of view, the most important of the tribe. Over 200 species are included in the sub-order, about 180 being comprised in the genus Smilax. The Sarsaparilla (q.v.) of commerce is the product of the roots of several species of Smilax; and the large fleshy tubers of *S. China*, a native of China and Japan, are regarded as nutritious and are used for food. *S. pseudo-China*, an American species, has similar tubers, which are used for making beer and for fattening hogs in some parts of the southern United States.

Smiles, SAMUEL, author of *Self-Help*, was born at Haddington in 1812. His family owed much to the intelligence, shrewdness, and force of character of their mother, who, when left a widow with a family of eleven, continued successfully to conduct a small business. Samuel Smiles had artistic leanings, but studied medicine in Edinburgh, took his degree when he was twenty, and published at his own expense a work on *Physical Education* (1838). At first he practised in Haddington as a medical man with small success, lectured on chemistry, and wrote articles for an Edinburgh newspaper. He settled as a surgeon in Leeds, but abandoned this for the editorial chair of the *Leeds Times*. He became secretary of the Leeds and Thirsk Railway Company in 1845, and in 1854 secretary of the South-Eastern Railway, retiring in 1866. While at Leeds he came into contact with George Stephenson, and conceived the idea of writing his life, a work which he eventually accomplished (1857). *Self-Help* followed in 1859, and was soon an assured success, 20,000 copies being sold during the first year, and up till 1889 the sales had reached 150,000 copies, while the book had been translated into seventeen languages. Some young men in Leeds who met in the evening for self-education had asked Smiles 'to talk to them a bit;' though really written before, it was only after the success of Stephenson's life that *Self-Help* appeared. Henceforward his career was that of a popular author and compiler, varied by travel to the scenes of the labours of the characters he described. An attack of paralysis while he was engaged upon *Thrift* in 1871 yielded to complete rest and a change of employment. He received the degree of LL.D. from Edinburgh University in 1878.

To the *Self-Help* series of books he added *Character* (1871), *Thrift* (1875), *Duty* (1880), and *Life and Labour* (1887). Works which teach the same truths by example are *Lives of the Engineers* (1861); *Industrial Biography* (1863); *Lives of Boulton and Watt* (1865); *Thomas Edward* (1876); *George Moore* (1878); *Robert Dick* (1878); *James Nasmyth* (1883); *Men of Invention and Industry* (1884). Besides contributions to the *Quarterly Review*, he also published *The Huguenots in England* (1867), and *The Huguenots in France* (1873); *A Publisher and His Friends: John Murray* (1891); and *Jasmin, the Barber-poet* (1891). The main value of these books is their homely practical nature, and the enforcement of everyday precepts by example.

Smirke, SIR ROBERT, architect, was the son of Robert Smirke (1752-1845), a well-known painter and book-illustrator, and was born in London in 1780. He became R.A. in 1811, was architect to the Board of Works, and was knighted in 1831. He died at Cheltenham, 18th April 1867. Smirke's public buildings are usually classical, his domestic dwellings Gothic. London is full of his work. Covent Garden Theatre (1809) was his first great undertaking; the British Museum (1823-47) the greatest. Others of his buildings are the Mint, the Post-office, several of the clubs (including the Carlton), the College of Physicians, King's College, and courts of justice in various parts of the country. He was entrusted with the restoration of York Minster after the fire (1829). Lowther Castle is a specimen of his domestic architecture. His brother Sydney Smirke, R.A. (1799-1877), was associated with him in some of his labours.

Smith, one of the oldest and most wide-spread of English family names, not to be regarded as belonging to one but to very many distinct families. It is, of course, derived from the honourable trade of the smith; the smith being originally a worker in metal or wood, and so nearly equivalent (when not compounded as in goldsmith, locksmith, arrowsmith) to 'craftsman' or 'artificer.' At first the name was not hereditary, but was used as a description of the individual: in the 14th century we have John Smyth, son of Thomas Wright (John being a smith and Thomas a carpenter); John's son might be called William Smythson, and his daughter Mary Smythdoghter. But soon the name became purely hereditary; and it is obvious that there would be many founders of Smith families. Philip le Smethe, William le Smyt, Henry le Smeyt show ancient forms of the name; Smyth, Smythe, and Smijth (derived from a form with a dotted ẏ, Smẏth) are also old variants which still survive. Smithson, Smithman, Brownsmith, Redesmith, Nasmyth (= Nailsmith), &c. are derivative forms. Corresponding in meaning is the Latin *Faber;* French, *Le Fevre*, *Lefevre*, or *Lefebvre;* Italian, *Fabroni;* German, *Schmidt;* Dutch, *Smid* and *Smits*. The Celtic *Caird* and *Gow* are nearly equivalent. The English names Ferrier, Ferrers, Ferrars are from the Latin *Ferrarius*, 'farrier' or 'shoesmith.' See NAMES.

In the London directory the Smiths fill eight pages (averaging 200 entries) of the commercial section (as against four pages of Joneses, and four of Browns), and three in the Court directory—not all undistinguished. Sir Hugh Smithson, who married the heiress of the Percies (q.v.), was created Duke of Northumberland in 1776; the Viscounts Strangford were Smythes; and the widow of the Right Hon. William Henry Smith (q.v.) was in 1891 made Viscountess Hambleden. And there were in 1892 six baronets and twenty-four knights bearing the name of Smith (in its several spellings); and sixty entries in the index of Burke's *Peerage* testify to the aristocratic connections of the Smiths. There is a work by H. S. Grazebrook on *The Heraldry of Smith* (1870); and by F. M. Smith on *The Heraldry of Smith in Scotland* (1873). In English literature they constitute a mighty army: Allibone's *Dictionary of British and American Authors*, with its supplement (1891), enumerates no less than 1069 several and distinct authors of the name of Smith (seventy-five of them William Smith), without counting Smyths, &c. The editor of the *Dictionary of American Biography* has thought no less than 199 persons of the name worthy of notice in that work. To such exhaustiveness the present work cannot pretend; but besides the subjects of the 18 articles below, we add a list of 22 Smiths whose names are more or less familiar in philanthropy, literature, science, or art.

Anker Smith, engraver (1759-1819); Charles Roach Smith, antiquary (1805-90); Charlotte Smith, poet and novelist (1749-1806); Eli Smith, American missionary to Syria (1801-57); Sir Francis Pettit Smith, mechanical inventor (1808-74; see p. 404); George Smith, of Chichester, landscape-painter (1714-66); Gerrit Smith, American philanthropist (1797-1874); Henry Boynton Smith, D.D., American Presbyterian divine (1815-77); James Smith of Deanston, Scottish agriculturist (1789-1850); James Edward Smith, botanist (1759-1828); John Smith, mezzotint engraver (1652-1742); John Raphael Smith, painter and mezzotinter (1750-1812); John Pye Smith, D.D., LL.D., divine and geologist (1774-1851); John Stafford Smith, composer (1750-1836); Robert Angus Smith, Scottish chemist and hygienist, author of *Air and Rain*, &c. (1817-84); Robert Archibald Smith, composer of Scotch songs and psalm-tunes (1780-1829); Very Rev. Robert Payne Smith, Dean of Canterbury, orientalist and divine, Bampton Lecturer on Prophecy (born 1818); Sir Thomas Smith, Elizabethan statesman and scholar, author of *De Republica Anglorum* (1512-77); Thomas Smith, of Derby, painter (*c.* 1709-69); Thomas Southwood Smith, M.D., hygienist, author of *Philosophy of Health* and *Epidemics* (1790-1861); William Henry Smith, author of the philosophical novels *Thorndale* and *Gravenhurst* (1808-72); also Charles Piazzi Smyth, ex-astronomer-royal for Scotland (born 1819).

Smith, ADAM, the founder of political economy as a separate branch of human knowledge, was born in the town of Kirkcaldy, Fife, on 5th June 1723. His family belonged to the respectable middle class; his father was comptroller of the customs at the port of Kirkcaldy, and his mother, Margaret Douglas, was the daughter of a small Fifeshire laird. His father died a short time before his birth, and the boy was the object of the care and solicitude of a widowed mother, to whom he was closely attached, and who lived to be proud of his attainments. When he was no more than three years old the poor woman got a sad fright, from a calamity hardly known at the present day—the child was stolen by tinkers; but he was tracked and recovered by his uncle as they were seeking a hiding-place in the neighbouring wood of Leslie. This was the only adventure in his quiet life. After getting the usual burgh-school education in Kirkcaldy, he was sent, in 1737, to the university of Glasgow, where he seems to have devoted himself mainly to mathematics and natural philosophy, though Hutcheson was the professor of moral philosophy. He secured an exhibition on the Snell foundation, which took him to Balliol College, Oxford, where he studied for seven years, and left traditions as of a man of large acquirements and peculiar independence of thought. It is said that he was intended for the English Church, but if so his own convictions crossed the designs of his friends. He returned to Kirkcaldy, and lived for a while with his mother there in undisturbed seclusion and study. In 1748 he came to Edinburgh, where silently and unostentatiously he became one of the brilliant little circle of men of letters who were then rising to importance, amongst his friends being David Hume, John Home, Dr Hugh Blair, Lord Hailes, and Principal Robertson. In 1751 he got the chair of Logic in the university of Glasgow, and this was changed a year afterwards for that of Moral Philosophy. In 1759 appeared his *Theory of Moral Sentiments*, celebrated for its reference of the mental emotions to the one source of sympathy. The *Dissertation on the Origin of Languages* was published along with the later editions of this book. Both had a great reputation in their day, and, although they are now obscure books in comparison with that other by which the author's name is remembered, the position they held with respectable thinkers gave a hearing to his doctrines on political economy which they would hardly have otherwise obtained. In 1762 the university of Glasgow gave him the degree of Doctor of Laws. In the following year he undertook a task, which might at first seem very uncongenial to a mind like his, given to retired study and independent thought and action—he became 'governor' or travelling tutor to the young Duke of Buccleuch. He was then sedulously collecting materials for his great work, and no doubt the inducement to accept the office was the opportunity it gave him for travelling and seeing for himself. He had the opportunity of being nearly a year in Paris, and of mixing in the circle of renowned wits and philosophers of the reign of Louis XV., including Quesnay, Turgot, and Necker. In 1766 his engagement came to an end, and he returned to Kirkcaldy to live in the old house with his mother.

The year 1776 was an era in the history of the world as well as that of the Kirkcaldy recluse, by reason of the appearance of the *Inquiry into the Nature and Causes of the Wealth of Nations.* If there was any living man to whose works he was indebted for the leading principles of this book it was David Hume, and it was from him, as best understanding the fullness and completeness of the exposition, that it had its first emphatic welcome. He wrote immediately on receiving it: 'Euge! Belle! Dear Mr Smith, I am much pleased with your performance; and the perusal of it has taken me from a state of great anxiety. It was a work of so much expectation by yourself, by your friends, and by the public that I trembled for its appearance, but am now much relieved. Not but that the reading of it necessarily requires so much attention, and the public is disposed to give so little, that I shall still doubt, for some time, of its being at first very popular. But it has depth, and solidity, and acuteness, and is so much illustrated by curious facts that it must at last take the public attention.' This was not destined to be exactly the literary history of this great work. Its startling doctrines, fine clear style, and abundant illustration from curious facts took at first; but counteracting influences arose when people saw how far the new doctrines went in playing havoc with old prejudices. The French revolution set the mind of the country bigotedly against everything that breathed of innovation. It was known that the younger Pitt participated at first in Smith's free-trade notions, but he had afterwards, whether from permanent conviction or temporary policy, to put himself in the foremost ranks of the enemies of innovation. It was not until long after the terrors of that epoch and the nervous vicissitudes of the war had passed over that Smith's work had an opportunity of revolutionising the public mind on matters of trade and finance. It came up, as it were, the leader of a great literary host, for expounders long crowded in numbers round *The Wealth of Nations* as the text-book of sound economy. It has been made matter of reproach against this work that it is not systematic in its form and that its nomenclature is not exact. But its author was not arranging the results of established knowledge—he was rather pulling down existing structures, compounded of ignorance and prejudice. Nor, indeed, have those who have attempted to make an exact science out of political economy practically vindicated the reproach they have cast on him of being unmethodical. Whatever we may yet come to, very few portions indeed of political economy admit of being treated as exact science; it is too closely connected with human passions and energies, and consequently with special results and changes, to be so treated.

In 1776 he lost his friend David Hume. He watched by him on his death-bed, and wrote an account of his last illness and death in a memorable letter to Mr Strahan in London. Soon afterwards he established himself in London, and became a member of the club to which Reynolds, Garrick, and Johnson belonged, though with the last Smith's relations were not uniformly amicable. In 1778 he was made a Commissioner of Customs. The only effect of this was to bring him to Edinburgh, and increase his means for indulging in his favourite weakness, the collection of a fine library; for he was, as he called himself, a 'beau in his books.' He lost his worthy mother in 1784; in 1787 he was chosen Lord Rector of Glasgow University; and he died 17th July 1790.

Smith's position in the history of political economy, his relation to his predecessors the physiocratic school, and his influence on later economists have been considered in the article POLITICAL ECONOMY. It is a mistake to hold that the barren principle of *laissez-faire* was the teaching of Adam Smith. Smith held it to be the duty of the state to protect its citizens from infectious diseases, to endow by charter joint-stock companies with exclusive trading privileges, to enforce military training on all males, and to establish compulsory and cheap education; state intervention being, however, justified only where the work cannot be done by individuals, or not so well as by the state. Smith's works were edited in 5 vols. by Dugald Stewart in 1811–12, and contain, besides the *Theory of the Moral Sentiments* and the *Wealth of Nations*, essays on the first formation of languages, on the history of astronomy, ancient physics, and ancient logic, and on the imitative arts. There have been numerous editions of the *Wealth of Nations*, by M'Culloch (1850), Thorold Rogers (1880), and Professor Nicholson (1884). His system has been dealt with by all subsequent economists, and in all civilised languages. Dugald Stewart published a short memoir, read before the Royal Society of Edinburgh (1793; published 1811). There is a life by Farrer in the 'English Philosophers' series (1881), and by Haldane in the 'Great Writers' series (1887).

Smith, ALBERT, was born at Chertsey, Surrey, on 24th May 1816, and educated at Merchant Taylors' School. He entered the Middlesex Hospital, and, after in 1838 becoming an M.R.C.S., proceeded to Paris to complete his studies. He then commenced practice with his father, but soon relinquished it for lecturing and light literature, and published upwards of a score of books, some of which were illustrated by Leech. His novels include *The Adventures of Mr Ledbury* (1844), *Scattergood Family* (1845), *Marchioness of Brinvilliers* (1846), *Christopher Tadpole* (1848), and *The Pottleton Legacy* (1849); of his entertainments the most successful was 'The Ascent of Mont Blanc' (1852). He appeared in this at the Egyptian Hall only two days before his death, which took place at Fulham on 23d May 1860.

Smith, ALEXANDER, poet, was born 31st December 1830 at Kilmarnock, but was brought up at Paisley and Glasgow. He received the usual Scottish schooling, and then had to give up all thoughts of the ministry for his father's calling of pattern-designer in a Glasgow warehouse. Here he began to write verses, some of which gained admission to the *Glasgow Citizen*. Through George Gilfillan his *Life Drama* appeared in several issues of the London *Critic* (1851), and was reprinted the next year in a volume of which 10,000 copies sold in a very few months. A reaction, however, set in; and the author had scarcely found himself famous when he began to be fiercely assailed. The faults of his book were obvious enough; every page bore evidence of immaturity and its natural result, extravagance; while a somewhat narrow reading having made him passionately attached to a few modern poets, such as Keats and Tennyson, their turns of expression reappeared in his verse, and gave colour to the charge of plagiarism which was carried to an absurd length. Still, he has always a richness and originality of imagery that more than atone for all defects of taste and knowledge; and no poet since Shakespeare's day has written occasional lines with a more Shakespearian ring. In 1854 he was appointed secretary to the university of Edinburgh, and next year produced *Sonnets on the War* in conjunction with Sydney Dobell (q.v.), his brother-poet in the 'Spasmodic' school. He afterwards wrote *City Poems* (1857); the Northumbrian epic, *Edwin of Deira* (1861); and, in semi-poetic prose, *Dreamthorp: a Book of Essays* (1863); *A Summer in Skye* (1865); and *Alfred Hagart's Household* (1866), a simple and touching story of Scottish middle-class life. In 1857 he married Miss Flora Macdonald from Skye; and he died at Wardie, near Edinburgh, 8th January 1867.

See the Rev. T. Brisbane's *Early Years of Alexander Smith* (1869), and the Memoir by P. P. Alexander prefixed to his *Last Leaves* (1869).

Smith, GEORGE, Assyriologist, was born of humble parentage in London on 26th March 1840. Whilst pursuing his trade of bank-note engraver he found means to study the cuneiform inscriptions in the British Museum, and through the kindly notice and assistance of Sir Henry Rawlinson and Dr Birch was in 1867 appointed an assistant in the department of antiquities in that museum. He helped the former to prepare the third volume of *Cuneiform Inscriptions* (1870), and through his skill as an interpreter of the Assyrian monumental writing not only was able to fix the dates of important events in the history of the East, but discovered the *Chaldæan Account of the Deluge* (1872). He likewise furnished (1871) the key to the interpretation of the Cypriote character and script. In 1872 he was sent by the proprietors of the *Daily Telegraph* to Nineveh in quest of discoveries; the collections he brought home were presented to the nation. The British Museum commissioned him (1873) to return and complete the excavations he had begun amongst the ruin-mounds of ancient Assyria, an account of which expedition, entitled *Assyrian Discoveries*, was published in 1875 (7th ed. 1883). Whilst on a third visit to the same regions he suddenly died at Aleppo, in Syria, on 19th August 1876. Besides the books quoted, he wrote *Annals of Assurbanipal* (1871), perhaps his most important publication; *History of Assyria* (1875); *Eponym Canon* (1875), a work on oriental chronology; *History of Babylonia* (ed. Professor Sayce, 1877); *History of Sennacherib* (ed. Professor Sayce, 1878); and papers contributed to *Translations of Biblical Archæology* and the first series of *Records of the Past*.

Smith, GOLDWIN, son of a Berkshire physician, was born at Reading, 13th August 1823. He received his education at Eton and Oxford, where he had a brilliant career, completed by a first-class in classics in 1845. In 1847 he was elected Fellow of University College, and in the same year he was called to the bar at Lincoln's Inn. He was nominated assistant-secretary to the first, and secretary to the second Oxford University Commission, and served on the Popular Education Commission in 1858. He was regius professor of History at Oxford from 1858 till 1866. During the American civil war he was a strenuous upholder of the North, writing several pamphlets in support of the Federal cause, and in 1864 lectured in the United States. In 1868 he was elected to the chair of English and Constitutional History in the Cornell University at Ithaca, New York. In 1871 he settled in Canada, where he became a member of the senate of Toronto University. He edited the *Canadian Monthly*, 1872–74, and founded and for a time edited *The Week* and *The Bystander*. He regards the annexation of Canada to the United States as inevitable, and strongly advocates commercial union or complete reciprocity between the two. He has written much for periodicals, and has contributed to this Encyclopædia. Among his works are *Irish History and Irish Character* (1861); *Lectures on the Study of History* (1861); *Rational Religion* (1861); *Empire* (1863); *The Civil War in America* (1866); *Three English Statesmen* (Pym, Hampden, and Cromwell, 1867; new ed. 1882); *A Short History of England* (1869); *The Political Destiny of Canada* (1879); *Cowper* (in the 'Men of Letters' series, 1880); *Lectures and Essays* (1881); *Jane Austen* (1890).

Smith, HENRY JOHN STEPHEN, mathematician, was born in Dublin, November 2, 1826, and was educated at Rugby and Balliol College, Oxford, taking a double-first in 1849. In 1861 he became Savilian professor of Geometry. He died February 3, 1883. He was the greatest authority of his day on the theory of numbers (see his British Association *Reports* from 1859 to 1865), and also wrote on elliptic functions and modern geometry. In 1881 the French Academy offered their 'Grand Prix' for a demonstration of certain theorems, ignorant of the fact that they had already been demonstrated fourteen years before by Smith, to whom accordingly the prize of 3000 francs was awarded, but not till a month after his death. He was a man of great versatility, geniality, soundness of judgment, and delicacy of humour.

Smith, JAMES and HORACE, authors of *The Rejected Addresses*, were the sons of an eminent London solicitor, and were born, the former on 10th February 1775, the latter on 31st December 1779. Both were educated at Chigwell in Essex. James succeeded his father as solicitor to the Board of Ordnance; Horace adopted the profession of a stockbroker, and realised a handsome fortune, on which he retired with his family to Brighton. Both were popular and accomplished men—James remarkable for his gaiety and conversational powers, and Horace—the wealthier of the two—distinguished for true liberality and benevolence. Both had written for the *Pic-nic* (1802), the *Monthly Mirror* (1807–10), &c., when the committee of management advertised for an address to be spoken at the opening of the new Drury Lane Theatre in 1812, and the brothers adopted a suggestion made to them, that they should write a series of supposed 'Rejected Addresses.' They accomplished the task in six weeks—James furnishing imitations of Wordsworth, Southey, Coleridge, Crabbe, Cobbett, &c., and Horace those of Scott, Byron (all but the first stanza), 'Monk' Lewis, Moore, W. T. Fitzgerald, and others. In point of talent the authors were about equally matched; for though James had the greatest number of successful imitations, the most felicitous of the whole is Horace's 'Tale of Drury Lane, by W.S.' ('I must have done this myself,' said Walter Scott, 'although I forget on what occasion.') It is a curious fact in literary history that the *Rejected Addresses* should themselves have suffered rejection, and that the copyright, offered originally to Murray for £20 and refused, was purchased by him for £131 in 1819, after the book had run through sixteen editions, and had brought its authors over £1000. James was afterwards an occasional contributor to the periodical literature of the day, and received £1000 for writing Charles Mathews' 'entertainments.' Horace between 1807 and 1845 produced more than a score of three-volume novels—*Brambletye House*, *Tor Hill*, &c. These are forgotten, but a new edition of his *Tin Trumpet* (1836) appeared in 1869, in which year also an *édition de luxe* of the *Rejected Addresses* was published at New York. Of Horace's *Poems* (2 vols. 1846) the best known is the 'Ode to an Egyptian Mummy.' James died in London on 24th December 1839, and Horace at Tunbridge Wells on 12th July 1849.

See PARODY; also vol. i. of Hayward's *Biographical and Critical Essays* (1858), and Timbs's *Lives of the Wits and Humourists* (1862).

Smith, JOHN, one of the Cambridge Platonists, was born early in 1616, the son of a small farmer at Achurch, near Oundle, in Northamptonshire. At eighteen he entered Emmanuel College, Cambridge, as a sizar, had Whichcote for his tutor, graduated B.A. in 1640, but missed a fellowship in his own college, as another Northamptonshire man already held one. However, the Earl of Manchester's clearances at Queen's College opened up for him a fellowship there in June 1644. Here he laboured with diligence as Hebrew lecturer, Censor Philosophicus, Greek Prælector, and became in 1650 Dean of the college and Catechist. But his feeble health gave way, and he died, after a long illness borne with saintly patience, 7th August 1652, and was buried in the college chapel. His funeral sermon was preached by Simon Patrick, who wrote long after in his *Autobiography*, 'Blessed be God for the good I got by him while he lived.' His *Select Discourses* was published in 1660, again in 1673, in 1821, and at the Cambridge press in 1859. A selection was edited by Lord Hailes in 1756. The subjects of these Discourses are the True Way of attaining to Divine Knowledge, Superstition, the Immortality of the Soul, the Existence and Nature of God, Prophecy, Legal and Evangelical Righteousness, the Shortness of a Pharisaical Righteousness, the Christian's Conflicts with, and Conquests over, Satan, and the Excellency and Nobleness of True Religion—the last an especially admirable treatise, marked at once by strong thought and spiritual inwardness.

Smith, CAPTAIN JOHN, adventurer and explorer, was born at Willoughby, Lincolnshire, in 1580, and was educated at the schools of Alford and Louth. On his father's death in 1596 he made up his mind to go to sea, but instead his guardian bound him apprentice to a merchant of Lynn. Business not being to his mind, he accompanied the second son of Lord Willoughby to France, and at Havre saw some soldiering under Henry IV. Next we find him in the Low Countries, whence he crossed to Scotland, returned to Willoughby, lived in a wood and studied Machiavelli and Marcus Aurelius, and exercised himself on a good horse with lance and ring. As the Turks were at that time ravaging Hungary he made up his mind to join the Christian army, and was robbed by four adventurers in France on his way thither. He joined a half-merchant, half-pirate, and in coasting round Italy and the north of Africa they were enriched by the capture of a Venetian argosy. Next at Grätz, in Styria, he entered the service of Ferdinand, Duke of Austria, under whom he greatly distinguished himself, and had some astonishing adventures. He was sold as a slave and marched to Adrianople, but escaped and travelled through Germany, France, Spain, and Morocco. After a sea-fight with two Spanish men-of-war he returned to England in 1604 enriched with 1000 ducats. In 1605 he joined the expedition of a London company to colonise Virginia. In April 1607 Jamestown was founded on the James River. On the way out Smith had been accused of conspiracy and narrowly escaped hanging, but in June 1607 he had his full liberty, and was admitted to the governing council. There was a desperate scarcity of food, and in endeavouring to find supplies, he fell into the hands of Powhatan, an Indian chief, and was only saved from being clubbed to death by the intervention of the Princess Pocahontas (q.v.). Smith was elected President of the colony in 1608, but returned to England disabled by an accident with gunpowder towards the end of 1609. During 1610-17 he was again in North Virginia; and he died in London, 21st June 1631. His works include *A True Relation of Occurrences in Virginia* (1608), *A Description of New England* (1616), *New England's Trials* (1620), *General History of Virginia* (1624), and *True Travels of Captain John Smith* (1630). In Charles Deane's edition of *A True Relation* (Boston, 1866) doubts were first raised as to the veracity of the Pocahontas story. Professor Arber, who edited a careful reprint of Smith's works in 1884, believes in him implicitly; but doubts are again raised in Henry Adams' *Historical Essays* (1892). There are Lives by Scheibler (1782), Sparks (1834), Simms (1843), Warner (1881), and Ashton (1884).

Smith, JOSEPH. See MORMONS.

Smith, ROBERT, whose name lives in the Smith's Prizes at Cambridge, was born in 1689, and was cousin to the mathematician Roger Cotes, whom he succeeded as Plumian professor of Astronomy at Cambridge in 1716. He succeeded Bentley as master of Trinity College in 1742, published *Harmonia Mensurarum* (1722), *A Complete System of Optics* (1738), and *Harmonics, or the Philosophy of Musical Sounds* (1748), edited the *Lectures on Hydrostatics and Pneumatics* of Cotes in 1737, and died at Cambridge in 1768.—The two Smith Prizes, now amounting to about £23 each, are, by a Grace of October 1883, awarded annually for the essays of greatest merit on any subject in mathematics or natural philosophy by recent B.A.'s. Holders have been Henry Martyn, J. Herschel, Whewell, Airy, Colenso, Stokes, Cayley, J. C. Adams, Thomson, Tait, and Clerk-Maxwell.

Smith, SIR SIDNEY. See WILLIAM SIDNEY SMITH.

Smith, SYDNEY, wit and reformer, was born at Woodford, Essex, on 3d June 1771, the second in a family of four sons and one daughter. His father, Robert Smith (1739-1827), was a clever eccentric, who 'bought, altered, spoilt, and then sold about nineteen different places in England;' from his mother, Maria Olier (died 1802), the daughter of a French Huguenot, he derived all his finest qualities. After five years at Southampton, in 1782 he was sent to Winchester, where he rose to be captain of the school, and whence, having first spent six months at Mont Villiers in Normandy, in 1789 he proceeded to New College, Oxford. He duly obtained a fellowship, but of only £100 a year, and in 1794 was ordained to the Wiltshire curacy of

Netheravon, near Amesbury. 'Mr Hicks-Beach,' he tells us, 'the squire, took a fancy to me, and requested me to go with his son to reside at Weimar; but Germany became the seat of war, and in stress of politics we put into Edinburgh, where I remained five years' (1798-1803). During this time he officiated in an Episcopal chapel there, and published *Six Sermons* (1800); married in 1800 a Miss Pybus of Cheam in Surrey; and in 1802, with Jeffrey, Horner, and Brougham, started the *Edinburgh Review* (q.v.), writing eighteen of the articles in the first four numbers. He next lived six years in London, and soon made his mark as a preacher, a lecturer at the Royal Institution on moral philosophy (1804-6), and a brilliant talker; but in 1809 'was suddenly caught up by the Archbishop of York, and transported to the living of Foston in Yorkshire, where there had not been a resident clergyman for 150 years,' but where he continued for twenty as 'village parson, village doctor, village comforter, village magistrate, and *Edinburgh* reviewer.' He farmed his glebe and built a parsonage, but was pinched in his means till in 1820 he came into £400 a year. In 1828 Lord Lyndhurst, the Tory chancellor, presented him to a prebend of Bristol, and next year enabled him to exchange Foston for the more desirable rectory of Combe-Florey in Somerset. In 1831 Earl Grey appointed him a canon residentiary of St Paul's, and this completed his round of ecclesiastical preferment. Visions of a mitre had sometimes crossed his waking dreams, but those dreams were never to be realised. However, he managed to 'grow old merrily' at Combe-Florey, which, in his own phrase, 'bound up well with London.' In London he died at his house, 56 Green Street, Grosvenor Square, on 22d February 1845. He is buried at Kensal Green.

Sydney Smith's writings include sixty-five articles, collected in 1839 from the *Edinburgh Review*, where they had appeared during 1802-27; *Peter Plymley's Letters* (1807-8), in favour of Catholic emancipation; *Three Letters to Archdeacon Singleton on the Ecclesiastical Commission* (1837-39); and other letters and pamphlets on the ballot, American repudiation, the game-laws, prison abuses, &c. They deal mainly with dead abuses and forgotten controversies, and their very success has consigned them to oblivion: who nowadays cares to study the cleverest arguments against seven years' transportation for poaching? So that their author is chiefly remembered as the creator of 'Mrs Partington,' the kindly sensible humorist who stands immeasurably above Theodore Hook, if a good way below Charles Lamb.

His Life (1855) was written by his daughter Saba (1802-66), who in 1834 married Dr (Sir) Henry Holland (q.v.); vol. ii. consists of selections from his Letters, edited by Mrs Austin. See also vol. i. of Hayward's *Biographical and Critical Essays* (1858), and Stuart J. Reid's *Life and Times of Sydney Smith* (1884).

Smith, Walter Chalmers, Scottish poet, was born in Aberdeen in 1824, studied at Old Aberdeen and Edinburgh, and, after holding a Presbyterian charge in London for some years, laboured as a minister of the Free Church at Orwell (Kinross-shire), in Edinburgh, in Glasgow, and again in Edinburgh in the Free High Church. Widely popular as an amiable and accomplished man and an admirable preacher, he has won the favour of a yet larger public by a series of volumes of poetry marked by richness of thought, creative imagination, and lyrical charm, although unequal and not seldom careless in construction. These are *The Bishop's Walk*, by 'Orwell' (1861); *Olrig Grange*, by 'Hermann Kunst' (1872); *Hilda among the Broken Gods* (1878); *Raban, or Life Splinters* (1880); *North-Country Folk* (1883); *Kildrostan, a Dramatic Poem* (1884); *Thoughts and Fancies for Sunday Evenings* (1887); *A Heretic* (1890).

Smith, William, called the Father of English Geology, was born at Churchill in Oxfordshire, 23d March 1769. He became a land surveyor and engineer, and so was naturally drawn to geology; and in 1794, after his appointment as engineer to the Somerset Coal Canal, he began his study of the strata of England. His epoch-making Geological Map of England was published in 1815, and from 1819 to 1824 he published, with self-denying zeal, no fewer than twenty-one geologically coloured maps of English counties, assisted in the latter task by his nephew and pupil, John Phillips, afterwards professor at Oxford. Smith received the LL.D. degree from Trinity College, Dublin, in 1835, and a pension of £100 from the crown in 1831. He died at Northampton, 28th August 1839. He was buried here, and thus had his wish to be buried in the Oolite as he had been born on it. See his *Memoirs* by Professor Phillips (1844).

Smith, William, eminent for his vast contribution to classical learning, was born in London in 1813, distinguished himself highly in Greek and Latin in the examinations of the university of London, and went through the course of law at Gray's Inn. But he began the real work of his life in 1840 with the publication of editions of the *Apology*, *Phædo*, and *Crito* of Socrates, and the *Agricola*, *Germania*, and part of the *Annals* of Tacitus. His great *Dictionary of Greek and Roman Antiquities* appeared in 1840-42, and was only superseded by its own third edition in 1891 (2 vols.). The *Dictionary of Greek and Roman Biography and Mythology* (3 vols. 1843-49) followed, and this magnificent series of classical handbooks was concluded by the *Dictionary of Greek and Roman Geography* (2 vols. 1853-57). Their learned editor next turned, and with still more striking success, to the task of preparing a series of smaller classical dictionaries for schools; and some years later still achieved further successes with his well-known series, *Principia Latina* and *Initia Græca*, on a method extended also to German and Italian. Students' manuals of history formed the next series of books he edited, including *Greece*, *Rome*, *France*, *Hume*, and *Hallam*. His complete edition of Gibbon's *Decline and Fall* appeared in 1854 (8 vols.); his serviceable *Latin-English Dictionary* in 1855; the *Student's Latin Grammar* in 1863; the *Manual of English Literature* in 1864; and the *English-Latin Dictionary* in 1870.

Another monumental group of works is his series of theological dictionaries: the famous *Dictionary of the Bible* (3 vols. 1860-63), now somewhat antiquated; *A Dictionary of Christian Antiquities*, in conjunction with Archdeacon Cheetham (2 vols. 1875-80); and *A Dictionary of Christian Biography, Literature, Sects, and Doctrines during the first eight Centuries*, in conjunction with Dr Wace (4 vols. 1877-87). Smith became editor of the *Quarterly Review* in 1867, and received the D.C.L. degree from Oxford in 1870.

Smith, William Henry, first Lord of Treasury and head of the firm of booksellers and newsagents that bears his name, was born in London, June 24, 1825. He was educated at the grammar-school, Tavistock, and while a youth entered his father's business, and rose step by step to be head of the firm. This, the largest wholesale newspaper business of the kind in Britain, was founded by his father (born 1792), who saw that the London newspapers, sent off by the evening coaches only, were not delivered in Manchester and Liverpool until forty-eight hours after publication. He conceived the idea of forwarding the papers by express parcel, with private coaches leaving London in the morning, so that the night coaches were overtaken, and the delivery of news secured twenty-four hours in advance. As the business expanded, to this was added the right of selling books and newspapers at railway stations (Birmingham Railway, 1849). Mr W. H. Smith was as strong in organising faculty as his father had been, and business was extended. He represented Westminster, 1868–85; was returned for the Strand in 1885 and again in 1886. He held the posts of Financial Secretary of the Treasury (1874–77), first Lord of the Admiralty (1877–80), Secretary of State for War (1885); in Lord Salisbury's ministry he was first Lord of the Treasury and leader of the House of Commons till his death, October 6, 1891. His widow was raised to the peerage as Viscountess Hambleden. He was distinguished for conscientious discharge of duty, and in 1889 received a handsome memorial from members of the House of Commons, and was entertained to a banquet. He was honorary D.C.L. of Oxford, and received the honorary freedom of the Stationers' Company in 1880. He left a fortune of £1,776,000 in personalty, besides several estates.

Smith, WILLIAM ROBERTSON, theologian and orientalist, was born at Keig, Aberdeenshire, on 8th November 1846. He received all his early training from his father, the Rev. William Pirie Smith, D.D., minister of the Free Church at Keig. He entered the university of Aberdeen in 1861, and graduated after an exceptionally brilliant career in 1865. He afterwards studied theology at the Free Church College, Edinburgh, at Bonn, and at Gottingen; while in Edinburgh he was also assistant to the professor of Physics (Professor P. G. Tait) in the university there. Immediately on the conclusion of his theological studies he was elected by the Free Church Assembly of 1870 to the vacant chair of Hebrew and Old Testament Exegesis in the Free Church College, Aberdeen; his suggestive inaugural address being *What History teaches us to seek in the Bible* (1870). At an early stage in the preparation of the ninth edition of the *Encyclopædia Britannica* he was invited to contribute articles upon Biblical subjects. The first of these ('Angel') appeared in 1875. That on 'Bible' (1875), a brief objective account of the now well-known historical and scientific facts of the subject, was almost immediately assailed on the ground of its heterodoxy—especially for its acceptance of the non-Mosaic authorship of Deuteronomy. (The question of the date of the Priestly writing—see PENTATEUCH—with Nöldeke on one side and Graf and Kuenen on the other, was at that early stage of the discussion left open in the encyclopædia article.) In consequence of the excitement that had been aroused, the Assembly of 1876 referred all Mr Smith's articles then published to a committee, which reported in 1877 that there was no ground for a heresy prosecution, but added that a majority of the members of the committee had found cause for 'alarm' and 'anxiety' in the article 'Bible' on account of its 'dangerous and unsettling tendency.' In these circumstances a prosecution for heresy was instituted before the Free Presbytery of Aberdeen. A long process ensued, in the course of which Mr Smith displayed remarkable debating talents, and in the end, after many vicissitudes in the various courts of the church, the trial resulted in the acquittal of the accused at the Assembly of 1880 by a majority of 7 in a house of nearly 600 members. In consequence, however, of the article on 'Hebrew Language and Literature,' which appeared in the *Ency. Brit.* in June 1880, Mr Smith was not allowed to resume his teaching duties during the following winter; and although no new heresy was alleged to have been broached in that article, he was removed from his chair without a trial by a considerable majority at the Assembly of 1881. Mr Smith, who, besides contributing largely to successive volumes of the *Encyclopædia Britannica*, had written several important pamphlets in connection with his trial, delivered at the request of a number of laymen in Edinburgh and Glasgow in 1880–81–82 two series of lectures substantially republished in the two well-known volumes entitled *The Old Testament in the Jewish Church* (1881) and *The Prophets of Israel* (1882). In 1881 Mr Smith transferred his residence to Edinburgh, and became actively associated with Professor Baynes in the editorship of the *Ency. Brit.*; on the death of his colleague he had the undivided responsibility of editor-in-chief. In the beginning of 1883 he was appointed Lord Almoner's professor of Arabic in the university of Cambridge, where shortly afterwards he was elected to a fellowship at Christ's College. His work on *Kinship and Marriage in Early Arabia* was published in 1885. In 1886 he was elected by the Cambridge senate to the university librarianship, which office he exchanged for the Adams professorship of Arabic in 1889. As Burnett lecturer he delivered at Aberdeen in 1889–91 three courses of lectures on the religion of the Semites; the first series was published as the *Religion of the Semites. Fundamental Institutions* (1889). Mr Smith received in February 1890 the honorary degree of D.D. from the university of Strasburg; the published éloge, which is understood to have been from the pen of the late Professor Reuss, particularises with justice and discrimination his conspicuous acumen, unsurpassed learning, indefatigability and success as a historical investigator, and sedulous and pious promotion of untrammelled criticism.

Smith, SIR WILLIAM SIDNEY, the hero of Acre, was born at Westminster, 21st July 1764, entered the navy at eleven, and received a lieutenancy for his courage at Cape St Vincent in 1780. After further service under Graves and Rodney, he rose to the rank of captain in 1782; gave advice to the king of Sweden in the war with Russia (1790–92), being knighted as a reward; was next sent on a mission to Constantinople, and aided Hood in burning the ships and the arsenal at Toulon in December 1793. He next watched the Channel for French privateers, but was taken prisoner in Havre-de-Grâce harbour in April 1796. He succeeded in making his escape in 1798, and in October was sent as plenipotentiary to Constantinople, whence he hastened to St Jean d'Acre on hearing that Bonaparte was about to attack. On the 16th March 1799 he captured the enemy's vessels, and he held the town heroically until Napoleon raised the siege, leaving his artillery behind, on the 20th May. For this he received the thanks of parliament and a pension of £1000. Sir Sidney Smith next aided Abercromby in Egypt, became rear-admiral of the blue in 1805, and successively guarded Sicily and Naples, destroyed the Turkish fleet in Abydos (1807), blockaded the Tagus, became vice-admiral of the blue in 1810, K.C.B. in 1815, and admiral in 1821. He died at Paris, 26th May 1840. See the Life by Barrow (1848).

Smithfield, or SMOOTHFIELD, is an open space of 5¾ acres in London, used for centuries as a market for sheep, horses, cattle, and hay. Being a little north of Newgate and west of Aldersgate, it was outside the city walls, and available for jousts, tournaments, executions, and burnings. It was also a place of recreation for the people, and the celebrated Bartholomew Fair (q.v.) was held in Smithfield. Here the patriot Wallace was executed by Edward I.; here in the great agrarian revolt Wat Tyler, at the head of 30,000 peasants, encountered Richard II., and was stabbed by Walworth, the Mayor of London; and it was here that many of the long line of martyrs from 1401 to 1612 suffered in the flames or on the scaffold. With the growth of the city the cattle-market became an intolerable nuisance (described in *Oliver Twist*), and was finally closed in 1855 (see SLAUGHTER-HOUSE). The hay-market goes on, but the centre of the space is laid out as a garden with fountains. The Smithfield Club (1798) holds its annual cattle shows in the Agricultural Hall.

Smithfield, a village (pop. 800) of Virginia, on a navigable creek 24 miles WNW. of Norfolk, contains in St Luke's Episcopal Church (1632; built of imported brick) the oldest Protestant building in America, and after the adobe cathedral at Santa Fé the oldest surviving Christian edifice in the United States.

Smithsonian Institution, at Washington, D.C., was organised by act of congress in 1846 in accordance with the will of James Macie Smithson (1765–1829), who, in a fit of pique at the Royal Society's rejection of a paper which he had submitted in 1826, bequeathed the reversion of an estate of £105,000 to the United States of America to found 'at Washington an establishment for the increase and diffusion of knowledge among men.' He was an Englishman, a natural son of Sir Hugh Smithson, first Duke of Northumberland, and Mrs Elizabeth Macie, a niece of Charles, Duke of Somerset. He devoted his life to scientific pursuits, especially to chemistry and mineralogy, was a Fellow of the Royal Society from 1787, and for long a member of the French Institute, and died in Genoa. The institution is a body of which the presiding officer *ex officio* is the president of the United States, and the Chief-justice of the United States customarily the chancellor. It is governed by a board of regents appointed by the Federal government, its direction under them being confided to a chief officer styled the Secretary. It has a spacious and beautiful building, forming one of the chief architectural adornments of the capital, which is occupied by offices and workrooms, but mainly by the collections of the government, which also fill a separate adjoining edifice covering nearly 2½ acres. In these buildings under its ownership or direction are the results of the exploring, surveying, geological, ethnological, and other expeditions of the Smithsonian and the government, known as the United States National Museum. The work of the institution is to promote original research; to publish the results of investigations, and distribute them freely to libraries in every land; to facilitate the interchange of scientific thought and labour, by sending and receiving free of cost the publications of all learned societies. It has a library of 100,000 volumes. Its publications consist of a quarto series, *Smithsonian Contributions to Knowledge*, an octavo series, *Miscellaneous Collections*, both published at the expense of the fund, and an annual Report printed by congress. The Smithsonian fund now consists of $703,000, on which and on all sums not to exceed a million dollars congress pays 6 per cent. interest. This is entirely distinct from the sums annually appropriated by government for the following bureaus of the institution: (1) the National Museum, (2) the Bureau of Ethnology, (3) the Bureau of International Exchanges, (4) the National Zoological Park, (5) the Astro-physical Observatory. These sums amount to about $300,000, which are placed under the direction of the Smithsonian Institution by congress. See *Nature*, vol. xl. p. 346.

Smith's Sound, one of the northern channels which connect Baffin Bay with the Arctic Ocean. See POLAR EXPLORATION, and map there.

Smock-frock, an outer garment of coarse white linen worn by agricultural labourers over their other clothes, especially in the south of England. It is like the French blouse, but longer; and the shoulders are often somewhat elaborately ornamented with neatly sewn folds and puckers.

Smoke, a common term to signify the volatile products of the imperfect combustion of such organic substances as wood or coal. The smoke from burning wood is almost colourless, consisting principally of carbonic acid and water, whilst that produced by burning coal is generally laden with oily and tarry vapour and finely divided carbon (or soot). The different effects resulting from the use of these varieties of fuel is exemplified in the brightness of Paris as compared with the (too generally) gloomy atmosphere of London. In London the smoke nuisance is an old grievance; Evelyn the diarist wrote his *Fumifugium* in 1661; and in his diary explains the unpleasantness of the great fog of the winter of 1684 (when a fair was held on the Thames), and justly ascribes it to the 'fuliginous steam of the sea-coale.'

The smoke nuisance may justly claim pre-eminence for itself in Great Britain, where coal is generally cheap, and where its users either from ignorance or prejudice refuse to adopt means for its proper combustion. In bright warm windy weather the smoke so produced is carried away from towns and factories, and becomes lost to view by mixing with the air; but in cold calm weather with an atmosphere saturated with moisture (or what is a true white fog) the smoke is arrested, and mixing with it gradually accumulates, and forming as it were a vast aerial emulsion of water vapour, tarry matter, and soot, gives rise to the black or brown fogs now so common in the large cities. With a view to the prevention of such a disagreeable and dangerous condition of the atmosphere much has been attempted, more especially by the Society for the Abatement of the Smoke Nuisance (see its *Memoirs*), but so far without beneficial results.

In this article there falls to be explained, first, the causation of such dark-coloured fogs; secondly, what has been done and what may yet be effected in the direction of their prevention. (1) When a microscopic slide is passed quickly over a smoky flame, a thin, semi-transparent film is left on the glass, which when examined under a powerful microscope presents the appearance of numerous particles of amorphous carbon in a finely divided condition, each particle being surrounded by an areola or coating of oily or tarry matter. This explains why a black fog may be and will remain persistent, even while rain is falling, each particle of carbon being, so to speak, surrounded by a waterproof coating which repels moisture. Aitken has conclusively proved that the cause of the separation of liquid water from a moisture-laden atmosphere or white fog is due to particles of fine dust present in the air (see FOG, Vol. IV. p. 706). We should therefore expect that the introduction of solid particles of carbon into such an atmosphere would have the same effect, which doubtless would be the case did not each particle repel the vaporous particles of water in its immediate neighbourhood; at the same time their density is insufficient to cause them to fall through the turgid atmosphere as smuts.

In a smoky town when a breeze prevails the smoke in its horizontal passage through the air gradually parts with its greasy-coated carbon to anything which impedes its progress, such as buildings, trees, &c.; so much so that only a few miles away it loses its dolorous aspect and assumes the soft, dreamy haze so dear to the painter, but which after all is only an air emulsion of finely attenuated particles of grease.

The densest fog of this kind on being agitated will deposit all its carbon as smuts, and become changed into a white fog or mist; therefore changes of temperature causing convection currents, or electrical discharges, will disperse the densest fog with extraordinary rapidity. In like manner such a fog finding its way into a dwelling-house is exposed to currents of dry heated air, in which the condensed moisture reassumes its gaseous or invisible condition, while the other constituents are deposited as a grimy coating upon its walls, furniture, &c. Likewise in breathing such a fog-laden atmosphere the carbon and oily products are arrested by the air-passages, and become apparent in the expectorated secretion from the bronchial tubes. A comparatively small amount of solid carbon and oily vapour may thus bring about atmospheric conditions wholly at variance with all ideas of beauty, comfort, and cleanliness. Of course with perfect combustion only carbonic acid and water vapour are the products; both being colourless vapours. There are numerous mechanical stokers by which the green fuel is gradually carried from the furnace doors to the fire bridge, by which means the smoke and tarry vapours given off during the distillation stage are forced over the mass of incandescent fuel occupying the posterior position in the furnace. In some cases the fuel is also by mechanical means fed from the bottom of the grate bars, by which means the same end is gained. The only objection to the general use of such stokers is the expense of erection, and the cost of upkeep.

(2) *Smoke Abatement.*—It has been pointed out that wherever smoke is agitated—e.g. by atmospheric or electric currents—its carbon is quickly deposited by its particles agglomerating into masses too heavy to remain in suspension. This may be simply shown, as, when smoke is agitated by fanners or air-currents in a closed space, in a short time it loses its characteristic black colour, the carbon being deposited as smuts (see 'Condensed Carbon Particles in Smoke,' *Jour. Soc. of Chem. Ind.*, vol. ix.).

Other plans by which smoke from furnaces is passed through water and washed have been tried with more or less success, and may come to be compulsorily adopted in factories, as is now the case with iron blast-furnaces, where the products—viz. carbon, hydrocarbons, ammonia, and even the carbonic and sulphurous acids present in all coal-smoke—are profitably utilised. From each ton of coal used in iron-smelting are obtained, of oil used for lucigens for burning, 64 lb.; pitch, 84 lb.; sulphate of ammonia, 20 lb.; the gross value about 3s. 6d., less charges. The net saving on each ton of coal may be taken at 2s., which is about one-fourth of the cost of the coal. By means of such appliances there is now no difficulty in preventing the emission of coloured smoke from any factory-chimney (Elliott's, Mond's, and other processes). But the real difficulty which meets all attempts at smoke abatement lies in the sentimental desire for the cheerful though smoky blaze of English house-fires. This causes, it has been estimated, in London alone the production of thousands of tons of black smuts per annum, which descend either on the city itself or in its immediate vicinity.

Long ago it was pointed out that to obtain the full advantage of the use of coal it should be carbonised—i.e. heated in closed retorts, when the whole of the volatile products, consisting of oil, tar, and gas (which latter is the immediate cause of the production of smuts), would be properly utilised, leaving a coke which would not only burn with a smokeless flame, but give out, weight for weight, a much larger amount of available heat than the uncarbonised coal. At the same time the inflammable gas (one of the products of this process) would either alone or mixed with the coke yield, when properly burned, a smokeless fuel for use in kitchens or fireplaces, thus doing away with this serious evil, as well as effecting an annual saving estimated by Macaulay at 45,000,000 tons of coal (representing a sum equal to £15,750,000) in Great Britain alone.

Many attempts have been made to effect this by constructing house-grates and cooking-ranges so that the raw coal is introduced from the bottom—i.e. at the fire-bars or grids, so that all gaseous products have to pass through an incandescent mass of carbon before reaching the chimney. But such attempts in general have failed, owing to the mechanical difficulties which have to be overcome and which would necessitate the entire reconstruction of the present house-heating arrangements.

In addition to the extreme discomfort and interruption to traffic which such fogs cause, it has hitherto been supposed that they seriously affect health; but it is comforting to know that the death-rate in such circumstances is not increased (see Russell's papers, publications of the Society for the Abatement of the Smoke Nuisance). Doubtless this may in part be owing to the well-known disinfecting properties of carbon and sulphurous acids, which are so largely in excess in the atmosphere at such periods.

Smoking. See HAM, PRESERVED PROVISIONS. For smoking tobacco and for smoker's sore throat, see TOBACCO.

Smolensk, a town of Russia, and an important railway centre, is situated on steep declivities overlooking the river Dnieper, 244 miles by rail W. by S. of Moscow. It is one of the oldest towns in the empire, having been a place of note in the 9th century, is surrounded by massive walls (now falling into ruin), has a cathedral of the 17th and 18th centuries, and was from the 14th century a powerful fortress, and as such an object of contention between the princes of Lithuania and Poland on the one side and of Moscow on the other. Here the Russians, under Barclay de Tolly and Bagration, were repulsed by Napoleon, August 17, 1812, when on his march for Moscow. Pop. 34,348.—The *government* has an area of 21,632 sq. m. and a pop. of 1,278,117. Almost all the land is farmed by peasant communes.

Smollett, TOBIAS GEORGE, physician, poet, novelist, journalist, historian, was a Dumbartonshire gentleman, belonging to that upper class of Scottish society—the lawyers and landed gentry—to which Sir Walter Scott also belonged. He was educated for the medical profession, but failed to make a living by it. He drifted into literature, and by it he made a precarious living and a lasting name. For the failure of his life in material success he was himself largely to blame. Handsome, upright, generous, of genuine humour, a pleasant companion on occasions, he yielded from his youth to (among other mischievous propensities) the evil habit of epigrammatic sarcasm on one or other of the company he was in. Proud, vindictive, of hot temper and haughty manner, as sensitive as he was satirical, he was a foreordained failure as a doctor, and foredoomed to quarrels, lawsuits, fine and imprisonment, and money difficulties in general as a journalist. The little poetry he wrote was not of great merit. His history was, as David Hume estimated it, a clever superficial review of the subject. It was the novels that made his name, and three of them maintain it.

Smollett was grandson of Sir James Smollett of Bonhill, advocate, member of the Scottish parliament, commissioner of the treaty of Union, and judge in the consistorial court. The fourth son of Sir James and his first wife, daughter of Aulay Macaulay of Ardencaple, was Archibald, who, without his father's sanction and without means to support a wife, married Barbara, daughter of Robert Cunningham of Gilbertfield, a young lady of good family but portionless. Sir James assigned to the imprudent couple Dalquhurn, the second house on the estate, and the few fields around it, on which stand now the villages of Alexandria and Renton. The third child of Archibald and Barbara was Tobias George, born at Dalquhurn, birthday not recorded, baptised on Sunday, March 19, 1721. His father died shortly after, and his grandfather in 1731. Sir James and his successor would seem to have behaved with reasonable kindness to the widow, a clever managing woman, and her three orphan children. Smollett went to Dumbarton grammar-school, was taught Latin well by John Love, and distinguished himself by the luxuriance of his boyish satire. He went to Glasgow College, attended arts and medical classes, and while attending them served an apprenticeship to John Gordon, doctor, apothecary, and very worthy man. It was thus he qualified for medical practice. Subsequently, in June 1750, he obtained the degree of M.D. from Marischal College, Aberdeen. In 1739 he went to London and tried to get *The Regicide, a Tragedy*, put on the stage. He failed, quarrelled with everybody about it, and published it ten years later with a very foolish preface. He romances about the ill-usage he and it underwent in the story of Melopoyn in *Roderick Random.* Smollett was appointed surgeon's mate on board the *Cumberland*, which sailed in 1740 to join Admiral Vernon's fleet, and took part in the unfortunate expedition to Carthagena in 1741. He describes that expedition in *Roderick Random*, and also in a *Compendium of Voyages and Travels* he published in 1756. His temper could not brook the service; he quitted it in the West Indies and tarried a while in Jamaica, where he met Anne Lascelles, the expectant heiress of 'a comfortable, though moderate, estate in the island.' In 1744 he set up house in London, in Downing Street, afterwards in Mayfair, to look for medical practice. He wrote *The Tears of Scotland* in a coffee-house in 1746. The same year he published *Advice, a Satire*—his first publication. Next year he published *Reproof, a Satire*, and married Anne Lascelles. *The Adventures of Roderick Random*, written autobiographically, appeared anonymously in 1748, and was at once a great success; Lady Mary Wortley Montagu thought the novel was Fielding's. It was heartless to caricature his grandfather as the Old Judge and Mr Gordon as Potion. In 1750 Smollett visited Paris along with Mr Moore—afterwards Dr Moore, novelist, father of Sir John Moore—and met Mark Akenside there. In 1751 was published, written biographically, *The Adventures of Peregrine Pickle.* It too had an instant success. The doctor, who gives an entertainment after the manner of the ancients, is a misrepresentation of Dr Akenside, and the laughable account of the feast is a satire on his pedantic affectation of Athenian manners. Smollett was paid for inserting 'The Memoirs of a Lady of Quality, Frances Hawes, Lady Vane,' which are a blot on the novel. He now tried to set up in Bath as a medical man, publishing *An Essay on the External Use of Water;* it was his last attempt of the kind, and it failed. Returning to London to live by his pen, he fixed his abode in Chelsea, and published *The Adventures of Ferdinand, Count Fathom* in 1753. The robber scene in the Black Forest, from that story of a gambler and swindler, has been the prototype of many such, and is a literary masterpiece. About this time an action was raised in the Court of King's Bench against Smollett for caning a person named Gordon. The verdict was in his favour, but the law-costs embarrassed him. In 1755 his translation of *Don Quixote*, which is still read, was favourably received. He became in 1756 editor of *The Critical Review*, a High Church and Tory monthly. Countless troubles to the editor culminated in 1759, when Admiral Knowles brought an action against the *Review*, and Smollett was fined £100 and sent three months to the King's Bench Prison. In 1756 he also began a *Complete History of England* from the time of Julius Cæsar's invasion down to 1748. He wrote the four quarto volumes in fourteen months, finishing the work in December 1757. This effort brought on chest disease and a scorbutic affection; he never enjoyed good health again. After coming out of prison he wrote a continuation of the history down to 1764, which is better known than the *Complete History;* for in Hume and Smollett's *History of England* the narrative of events from 1689 to 1760 is Smollett's. From all this labour on history he is 'said to have cleared £2000.' In 1757 his farce, *Reprisals, or the Tars of Old England*, was put on the stage by Garrick. Smollett toiled at compiling a universal history and translating Voltaire. *The Adventures of Sir Launcelot Greaves*, an English Don Quixote, appeared as a serial, 1760-61, in the *British Magazine*, a sixpenny monthly, and was published separately in 1762. Like all the novels Smollett wrote, it is weak in construction, but lacks neither vivacity nor wit. He edited *The Briton*, 1762–63, a weekly paper in support of Lord Bute's administration, received no reward, and was routed from the newspaper field by the *North Briton*, the organ of his former friend, John Wilkes. In April 1763 Elizabeth, his only child, died of consumption. He left England in June, sojourned on the Continent more than two years, and published in 1766 the still readable *Travels through France and Italy.* The same year he, broken in health, visited Scotland—his second visit since he left as a lad—and while in Edinburgh stayed with his mother and widowed sister. His health benefited by this journey, but on his return south it broke down again. He left England in 1768 to seek recovery in a warmer climate. He had the year before solicited a consulship at Nice or Leghorn—the only favour he ever asked from government—was refused it, and went to live in Italy, relying on his wife's small and always uncertain income and on his pen. He wrote the *Ode to Independence* about this time. *The History of the Adventures of an Atom*, a prose satire, in which political leaders are broadly caricatured under fictitious names, was published in 1769. In a village, called Monte Novo, near Leghorn, Smollett wrote, in weakness and much pain, the last and best of his novels, *The Expedition of Humphrey Clinker*, written in epistolary form. The 'Ode to Leven Water' occurs in it. It was published in 1771; and Smollett just lived to hear the first rumours of its success. He died, September 17, 1771, aged fifty-one, and was buried in the English cemetery, Leghorn. If he had lived four years longer he would have inherited the family estates; as it happened, he left his widow quite unprovided for. Her small income from the West Indies by and by failed entirely, and there was a benefit performance in the Theatre Royal of Edinburgh in her behalf when she was destitute twelve years after his death. The novels which have become classics are the three in which Smollett himself is adumbrated as, respectively, the Scottish Roderick Random, the English Peregrine Pickle, and the Welsh Matthew Bramble.

Plays and Poems, with Memoir (1 vol. 12mo. 1784). *Miscellaneous Works*, first collected by David Ramsay of the *Edinburgh Evening Courant;* humorous frontispieces by Rowlandson; meagre life (6 vols. 8vo. Edin. 1790; does not contain *Adventures of an Atom*).

Miscellaneous Works, with Memoir, by Robert Anderson, M.D., carefully edited (6 vols. 8vo. Glasgow, 1796); *Expedition to Carthagena* added to 2d edition (6th ed. 1820). *Works, with Memoir*, by John Moore, M.D. (8 vols. 8vo. Lond. 1797), carelessly edited; memoir valuable owing to personal intimacy. *Miscellaneous Works, with Memoir*, by Thos. Roscoe (1 vol. large 8vo. Lond. 1840; many editions—latest, 1878; New York, 1857, 6 vols. 12mo.). Sir W. Scott's Biographical Prefaces, published separately (2 vols. 12mo. Paris, 1825). *Life and Selections*, by Robert Chambers, LL.D. (1867). *Life*, by D. Hannay ('Great Writers' series, 1887). *Works*, carefully selected—the three classical novels, the plays, the poems—with Life and Notes by the present writer; Notes fill up blanks left by Smollett (1877). See also Hazlitt's *Comic Writers*, Thackeray's *Humourists*, and Masson's *British Novelists*.

Smolt, a name given to young river salmon when they are bluish along the upper half of the body and silvery along the sides.

Smuggling, originally and strictly a crime of commerce, a violation of customs laws, to be distinguished from such a crime of manufacture as illicit distillation, which violates excise laws. But the term is commonly applied also to the evasive manufacture and disposal of commodities liable to excise as well as to the clandestine importation of articles on which customs duties have been imposed (see CUSTOMS DUTIES, EXCISE). Defrauding the government of revenue by the evasion of customs duties or excise taxes may therefore serve as a definition. The evasion of customs duties is the prevailing sense of the term in the popular mind, a sense in which there are in all nations stirring stories of smuggling rich in romantic incident. But, in the accepted use of language, the other sense is quite common. A case reported (June 1891) in the leading newspapers, as 'Smuggling in London,' was that of two men brought before a police-court on the charge of defrauding the revenue by illicit distillation in a warehouse in Holborn. A great deal of smuggling of the manufacturing kind is constantly carried on all over Great Britain and Ireland. The government is regularly defrauded of revenue in this way to a far greater amount, it is believed, than it is now by the commercial smuggling reported annually by the commissioners of customs. We read frequently of raids by revenue officers on smuggling bothies in the Highlands of Scotland. In July 1891 an important seizure was reported to have been made in one of the haunts of a smuggling fraternity on the Gairloch, between whom and the people of the Outer Hebrides, where no distilleries exist, a brisk trade in spirits is carried on. But men well qualified to form a correct opinion believe that the revenue is defrauded by illicit distillation all over the country a great deal more than it is in the wild districts of the north. In the manufacturing centres skilful mechanics make their own utensils and tools for the purpose, and repair and alter them easily. The Highlanders are obviously at a disadvantage in this respect. Since the duty was taken off malt by Mr Gladstone in 1880 there have been facilities for this kind of smuggling which, there is good reason to believe, have been taken advantage of in the cities and manufacturing towns, and an occasional find of the kind is reported. But the revenue of the country is buoyant, and it is not desirable to make too frequent exposure of crimes so obviously created by act of parliament; the chiefs of the excise branch of the inland revenue department do not, accordingly, encourage too curious enquiry on the part of local revenue officers. In these circumstances exact information on the subject is not available.

Smuggling, in the sense of evading customs duties by dealing in contraband goods, has ceased to deserve the name of a trade in the United Kingdom. From about the close of the 17th century to nearly the middle of the 19th century the suppression of that kind of free trade by vigorous methods of prevention engaged the close attention of the inland revenue department. Free trade as a national policy has put down the smuggling trade. Only a very small number of persons comparatively deal in contraband goods now. But when the duties on spirits were higher in England than in Scotland, Northumberland and Cumberland were haunted with smugglers. Haddington and Berwick and the Scottish counties on the Solway were long demoralised by unwise tariffs on articles of import from abroad. Readers of Scott's novels know the effective use he makes of smuggling for the purposes of his art in *Guy Mannering* and *Redgauntlet*. Robert Burns was an exciseman, and it was also one of his duties to prevent the smuggling of contraband goods. It is well known how in 1792 he placed himself on one occasion at the head of the revenue officers and a guard of dragoons, waded the Solway sword in hand, was the first to board a smuggling brig, captured the crew, and had the brig sold at Dumfries. It was on that occasion that Burns wrote 'The Deil's awa' wi' the Exciseman.' The exploits of smugglers and coastguardsmen in the frequent and bloody encounters that took place constitute the main interest of many an exciting tale.

The contrabandista used to be one of the most popular characters in Spain. The exports from England to Gibraltar, to refer only to one of his lines of activity, used to be large, and were introduced by smugglers to the interior of Spain. It was remarked fifty years ago or more that it would be nearly impossible to prevent the smuggling of British goods into the United States on the Canadian frontier if the duties on importation were excessive. These duties are now very excessive, and inferences are allowable; but the United States government does not compile statistics of smuggling either by the frontier or by the ports. The injudicious tariffs which used to be imposed by both England and France encouraged smuggling to an enormous extent on both sides of the English Channel; spirits, especially brandy, tea, tobacco, silk goods from France; from England the most important article of illicit trade was cotton-twist. English goods were introduced into France chiefly by the Belgian frontier, and dogs were trained to convey them; a dog would convey goods worth from £20 to £50. There used to be cruel slaughter of these dogs, a reward of three francs being given by the customs authorities for every one seized. A great historical outburst of smuggling was the answer which commercial enterprise gave to Napoleon's Berlin and Milan decrees. Silk from Italy reached England by Smyrna after being a year on passage, by Archangel after being two years. Cotton-twist, coffee, sugar, tobacco were shipped from England to Salonica, conveyed thence by mules and horses through Servia and Hungary to Vienna, and distributed over the Continent from that capital. Coffee from London would reach Calais by Vienna. The risks and expense raised the price of sugar on the Continent to 6s. a pound.

In 1831 an official report estimated the loss by smuggling to the British revenue as exceeding £800,000 a year (in French brandy to the extent of £500,000). Three-fourths of the tobacco consumed in Ireland was smuggled; the total annual cost of protecting the revenue was then from £700,000 to £800,000. In 1840 it was believed that 48 per cent. of French silks paid no duty. The south coast of England, especially Kent and Sussex, was largely addicted to the smuggling trade with France, by which it was stated that goods to the value of £2,000,000 were conveyed into France from England by the Belgian frontier alone. Till a comparatively recent date the Isle of Man (q.v.) was a great emporium for smuggling into England, Scotland, and Ireland.

In the *Cornhill Magazine* for June 1891 there is an article on smuggling still carried on across the Swiss French frontier. Tobacco, sugar, and coffee are smuggled from Switzerland into France; cattle, gunpowder, and household goods from France to Switzerland. 'The smugglers usually pass the frontier,' says the writer, 'by a dangerous passage across the river Doubs and the rocks of its vicinity, called the Saut du Doubs. The perils of this romantically beautiful passage are increased by the darkness, the fear of custom-house officers, and by heavy packages of contraband goods which impede the free use of the limbs. Each man is armed with an alpenstock and a pistol; he carries his burden fastened to his back by a heavy strap which can be detached and the bundle rolled down the adjacent precipice at the first signal of danger and pursuit.' Such is the serious business of men who make smuggling a trade on that frontier. But, in a less risky way, 'wagoners, dogs, travellers, railway officials, and even the custom-house officers themselves are all more or less engaged in smuggling. . . . Ladies, ever alive to the delights of a bargain, are inveterate smugglers.' The writer tells us that the smugglers who make a business of it are admired and aided by the peasants on both sides of the frontier. Morality is popularly regarded as immutable, and tariffs are very mutable. The people never did associate ideas of right and wrong with smuggling in any country. The smuggler was everywhere regarded as a benefactor, because the people believed that he supplied better articles at a cheaper rate than those on which customs or excise duties were paid. Adam Smith put this strongly when he said that to pretend to have any scruple about buying smuggled goods would in most countries be regarded as a pedantic piece of hypocrisy.

The principal articles liable to duty at present in the United Kingdom are cocoa, coffee, currants, raisins, rum, brandy, wine, tea, tobacco. The following statement concerning smuggling during each of the years specified was issued towards the close of the year 1890 by the commissioners of Her Majesty's customs:

Year ended 31st March	Total Number of Seizures of Smuggled Goods of all kinds	Number of Seizures of Tobacco, Cigars, and Foreign Spirits.	Quantities seized		Number of Persons convicted.			Penalties recovered	
			Tobacco and Cigars	Foreign Spirits.	In Summary Cases	In Non-Summary Cases	Total	Number.	Amount
			Lbs	Gals					£
1881	1391	1265	21,473	197	1146	67	1213		
1882	1698	1540	25,653	432	1124	92	1216	1395	3529
1883	1709	1601	20,454	194	1128	30	1158	1352	3956
1884	2238	2110	24,536	514	1708	99	1807	1663	7302
1885	2608	2445	17,485	141	1849	101	1950	1793	4589
1886	2641	2426	18,072	162	1893	98	1991	1876	4122
1887	2677	2344	23,657	479	1695	108	1803	1606	1041
1888	2860	2477	20,185	467	1667	83	1750	1666	3508
1889	4354	4200	16,246	535	3224	70	3294	3294	5909
1890	5518	5206	18,081	187	4141	56	4197	4432	8088

Summary cases are disposed of by the magistrates, and are those in which the quantity of tobacco and cigars seized does not exceed 20 lb., of spirits not above five gallons. Larger quantities are dealt with by information and summons as non-summary cases. Of the £7302 of penalties recovered in 1884 £3142 were paid by two parties. It will be seen that the total number of seizures in the year ended 31st March 1890 exceeds those of the previous year by 1164. About 1000 of these were seizures of tobacco in various forms or of spirits. The quantity of tobacco again exceeds that seized in the previous year by 1838 lb.; while of spirits seized there were only 187 gallons as against 535 gallons—a remarkable decrease. The total increase of seizures in the year 1890, therefore, may be taken, so the commissioners say, to consist of small quantities of tobacco or cigars, averaging from 1 lb to 2 lb in weight. It will be seen again that while there was an increase of 1203 in the total number of persons prosecuted, there were only 70 non-summary cases in 1889, 56 in 1890, a decrease of 14; and the penalties show an average of £2 a head. The figures, as thus compared, show a large number of attempts to smuggle tobacco in small quantities. This is confirmed by the following curious item of information supplied by the commissioners: 'The larger seizures dealt with by summons and prosecution comprise several instances of the seizure of tobacco stalks landed from vessels belonging to the royal navy. Tobacco is issued to the crews of H.M. ships of the navy in the form of unmanufactured leaf, and, in preparing it for use, the men remove the mid-rib of the leaf, which they are enjoined by regulations to destroy; the landing of the stalk, formed by the mid rib when separated from the leaf, being prohibited by law. Under the existing law . . . drawback can be claimed upon snuff produced by grinding up stalks and other tobacco refuse, and a considerable trade has existed in consequence in certain localities, with the intervention of the receivers, between seamen and others employed on board H.M. ships and persons who purchase stalks for the purpose of obtaining drawback upon the snuff produced from them. In several cases prosecutions have been successfully instituted, and it is hoped that a check has been put to this illegal traffic.' The figures show also that tobacco and spirits are now practically the only articles smuggled, and that the quantity of these so dealt with is comparatively infinitesimal.

See W. D. Chester, *Chronicles of the Customs Department* (1885); Lieut. H. N. Shore, *Smuggling Days and Smuggling Ways* (1892); also the articles COASTGUARD, TAXATION.

Smut, or BUNT (sometimes also called Dustbrand), is the popular name of certain small fungi which infest flowering land-plants, especially the grasses. This name is derived from the appearance of the spores, which are nearly black and very numerous. At the present time the group is called the Ustilagineæ. Some of them live in the intercellular spaces only, others penetrate the walls of the cells, especially of the parenchyma (simple) cells, and live within the living matter of the plant. Some species attack a part only of their host—e.g. Entyloma forms pustules on the leaves of certain species of Ranunculus, others spread throughout the tissues, forming spores in special places. Thus the mycelium of *Tilletia caries*, which causes the disease specially known as Bunt, may spread through the whole of a wheat-plant, but the spores are found only in the ovary. *U. Carbo* fructifies in the inflorescences of various grasses, and causes the disease known as Smut. The part of the plant where the fructification is being formed is generally enlarged, and becomes filled with the black resting spores. This swelling is especially noticeable in maize-plants attacked by *U. Maidis*. The mycelial hyphæ are not very densely spread within the tissues of a host, but the hyphæ that will bear spores branch repeatedly, and thus form a mass of compact tissue within that part of the host selected for the fructification, this compact mass taking the form of that part of the host, or covering with a flat layer a part of the surface, or eating a cavity out of the tissues of the plant and taking the form of that cavity. Generally the spore bearing hyphæ become transformed into spores, so that nothing but spores remain, but some species form definite envelopes for the spores—e.g. Doassansia. The germination of the spores occurs when they have been well saturated with water. Typically, a germ tube is emitted which is called the promycelium. This, in most cases, gives forth from the far end a number (4 to 10) of smaller tubes, called sporidia. These sporidia, either before or after their separation from the promycelium, conjugate in pairs. From these conjugated cells there may arise a tube which takes all the protoplasm of the two cells; this tube, called an incipient mycelium, may enter into the tissues of a host and develop a true mycelium. Sometimes in a species which usually develops in this way any or all of these steps may be omitted—e.g the spore may give rise to an incipient mycelium direct, or the sporidia though formed may not conjugate, but produce incipient mycelia direct. Species also occur in which these peculiarities are the general rule. In some species the sporidia, or what correspond to them, are occasionally formed direct from the hyphæ within the plant, the formation of a true resting spore being omitted; the parts so formed project from the host and are called gonidia.

See FUNGI; also De Bary's *Comparative Morphology of Fungi, Mycetozoa, and Bacteria*, or Goebel's *Outlines of Classification and Morphology*.

Smyrna, the most important seaport of Asia Minor, stands at the head of the Gulf of Smyrna, which penetrates 46 miles inland from the Ægean Sea, and in a little mountain-girdled valley on the west coast of Asia Minor. The city climbs up the slopes and nestles at the foot of a steep hill (at the south-east corner of the Gulf), which is crowned by the ruins of the ancient Greek Acropolis. Viewed from the waters of the Gulf it presents a very fine appearance; but the interior, especially in the higher parts where the Turks dwell, consists chiefly of narrow and dark streets with mean houses. The Frankish quarter, to which the Europeans are confined, and which faces the quays (2 miles long) and harbour, is in most respects decidedly better than the native districts. Gas is used for lighting the streets, and the electric light in private establishments. The drainage is bad; the climate uncertain, but intensely hot in summer; and earthquakes are by no means unknown, those of 178 A.D., 1688, 1768, and 1880 having been particularly severe. Traces of the ancient walls, the stadium, theatre, and some temples can still be discerned. There are a great number of modern mosques, churches, baths, and bazaars, but no buildings with any architectural pretensions. The city is the seat of archbishops of the Roman Catholic, Greek, and Armenian Churches, and of the Turkish governor-general of the province (*vilayet*) of Aidin. Carpets are manufactured, as well as pottery, cottons, and woollens. Smyrna is the starting-point of two lines of railway that run eastwards into the interior of Asia Minor—one (300 miles long) up the Mæander valley, the other (170 miles long) up the Hermus valley; and in connection with these iron-foundries and machine-shops have been established at Smyrna. But it is as a commercial seaport that the place is specially celebrated. Seven hundred years before Christ it was one of the principal trading centres for Asia Minor (Anatolia); and at the present day it has unquestionably the lion's share of the Asia Minor trade with Europe. The harbour is large, safe, and easily accessible, but is in imminent danger of silting up like that of Salonica. The exports from Smyrna average about £4,000,000 in annual value, and the imports close upon £3,000,000. The principal commodities amongst the exports are raisins (£1,100,000), valonia (£700,000), figs (£343,000), and opium (£196,000), to which must be added barley, carpets, sponges, liquorice, wool, olive-oil, tobacco, emery, sesame-seed, hides, fruits, antimony, beans, cotton seed, walnut-wood, poppy seed, bones, and a multitude of other articles. The imports of greatest value are textiles (£713,000), timber (£275,000), and iron and hardware (£102,000), besides groceries, railway plant, leather, butter, glass, petroleum, coal, cheese, matches, paper, &c. Britain takes of these exports to the value of £2,000,000 annually, and sends from £678,000 (1885) to £1,255,000 (1889) of the imports. The harbour is entered annually by some 1620 vessels of 1,486,000 tons burden. Pop. estimated (1890) at 210,000, of whom 107,000 are Greeks (just the population of Athens), 23,000 Jews, 12,000 Armenians, 12,700 Europeans, and the rest Turks.

Smyrna was originally a city of the Greek Æolic immigrants into Asia Minor, but some time before 688 B.C. it had become Ionian. During that century it enjoyed wonderful prosperity as the principal intermediary in trade between Europe (Greece) and Lydia; but in 630 B.C. it was captured and destroyed by Alyattes, king of Lydia. For more than three hundred years it maintained merely a struggling existence; but it was at length rebuilt on a different site by Antigonus, and further enlarged and fortified by Lysimachus, both inheritors of the conquests of Alexander the Great. Under the Romans its commercial fame was revived, though it had rivals in Ephesus and Pergamum, and at a later date a still more formidable rival in Byzantium, to the emperors of which it belonged. It was frequently sacked by the Turks and suffered many reverses, being destroyed by Tamerlane (1402) and finally captured by the Turks under Murad II. in 1424. See Rougon, *Smyrne. Situation Commerciale et Economique* (1892).

Snail, a term employed to designate the species of terrestrial Gasteropoda (*q.v.*) which have well-formed spiral shells. The more typical snails belong to the genus Helix, of the family Helicidæ, and have the shell of many whorls, globose, depressed, or conical. The aperture or mouth of the shell is more or less encroached upon by the last

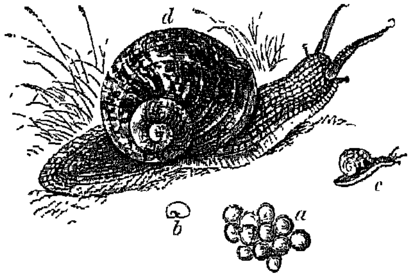

Fig. 1.—Common Snail (*Helix aspersa*): *a*, eggs; *b*, appearance when newly hatched; *c*, slightly advanced stage; *d*, mature snail.

whorl but one, it is often strengthened by an internal thickened rib, its edges are usually more or less reflexed, and there are sometimes calcareous tooth-like prominences known as the denticles or apertural *lamellæ*. The animal progresses upon a foot or sole, which is flattened beneath, and fringed at the edge. There are four retractile tentacles, the two upper ones the largest, and bearing the eyes. There is a crescent-shaped jaw, which is usually strongly ribbed. The tongue or lingual membrane bears very many teeth arranged in transverse rows. Thus, the Common Garden Snail has 135 rows of 105 teeth = 14.175 in all. Snails are hermaphrodite, but mutual impregnation takes place. They are provided with calcareous styles or darts, which are secreted within a sac, the dart-sac, from which they are protruded during copulation. The forms of these darts are very various, and sometimes offer excellent characters for the separation of allied species. The eggs of snails are round or oval, and are deposited in damp places or in the earth. Those of the Edible Snail are nearly as large as a pea. At the approach of winter, or in very dry weather, snails close the mouth of the shell with a membrane (*epiphragm*) formed by the drying of the mucous substance which they secrete, and become inactive and torpid. Some, as the Edible Snail, make a succession of such membranes, the outer one of which is also strengthened by a quantity of calcareous matter, the secretion being at first a white viscid fluid, but quickly hardening like plaster of Paris. When this is to be removed a fresh secretion of fluid mucus softens it at the edges. The Common Garden Snail is to some extent gregarious when in the torpid state: many individuals may frequently be found closely packed together in cracks in walls, under logs or stones, and in other sheltered places. Snails delight in warm moist weather, and are active chiefly at night and during or after rain. They are also more abundant on limestone soils than elsewhere; the kinds found in districts where there is little or no lime have frequently very thin shells, owing to the deficiency of calcareous matter to strengthen them. Snails feed chiefly on vegetable substances, although they are very indiscriminate in their appetite, and even devour the dead of their own kind. The mischief which they do to garden crops is too well known; and gardeners are constantly on the alert to destroy them. Thrushes and blackbirds devour great quantities of snails; they select a suitable stone against which they break the shells. These 'breaking-stones' may often be found in fields and by road-sides surrounded by fragments of shells. Snails possess in a very high degree the power of repairing injuries, and specimens may not rarely be found in which part of the shell has been broken and repaired again. Snails are found in nearly every part of the globe, some thousands of species having been described by authors. Seventy species are found in the British Islands, of which twenty-two belong to the genus Helix. The Edible Snail (*H. pomatia*) is sometimes called the Roman Snail, and is much esteemed as an article of food on the Continent. In Great Britain it is not much eaten, but there is at least one shop in London where it is sold for this purpose. It is a large tawny species, not rare in parts of the south of England, especially on the chalk downs of Kent and Surrey. The Common Garden Snail (*H. aspersa*) is the most destructive species in Britain. It is exceedingly abundant in most places, but rare in parts of Scotland and north-west England. It is also used for culinary purposes, notably in the Newcastle, Bristol, and Swindon districts. The Striped Snail (*H. nemoralis*) is smaller than the Garden Snail, and of various colours, usually red or yellow, ornamented with one to five spiral dark-brown bands. The rim or lip of the aperture in this species is dark brown, but in a closely allied species, *H. hortensis*, it is white. Both these species are very common, and it is a favourite custom for collectors to obtain large series showing the variation, their beauty and interest being very great. Taking variations in the banding alone, already eighty-nine of *H. nemoralis* and fifty of *H. hortensis* have been found within the British Islands, while very many others are known from abroad. *H. nemoralis*, when introduced into Virginia, produced many band-variations which are not known in Europe. *H. arbustorum* is a species about the same size as *H. nemoralis*, but brown, mottled with pale yellowish, and usually encircled by a single dark band. The Kentish Snail (*H. cantiana*) is smaller, whitish, more or less tinged with rufous. The Hairy Snail (*H. hispida*) is a small horn-coloured or brown species found in hedges, among moss, &c.; its shell is clothed with minute hairs or bristles. *H. virgata* is a species rather over ½-inch in diameter, found very abundantly in chalky places, on downs, and by the sea. It is usually white with one or more dark-brown bands, though some of the varieties are blackish or yellowish. On the South Downs this and an allied but smaller species (*H. caperata*) are so abundant that the sheep, when feeding upon the short grass, can scarcely avoid devouring them; and the excellency of the South Down and Dartmoor mutton has in part been attributed to the nutritive qualities of the snails. *H. ericetorum* is another species allied to *H. virgata*, and found in similar places, but it is larger and has the shell much flattened above. *H. pulchella* is a minute but very beautiful species, found abundantly both in Europe and North America. Hyalinia (often called Zonites) is a genus of small snails in which the jaw is without ribs, and the shell smooth and shiny. There are eleven British species. Some of them emit a garlic odour, especially *H. alliaria*. *H. crystallina* is a small species of a clear white colour. The genus Pupa consists of brown cylindrical shells, resembling small seeds. Some of them, which are placed in the sub-genus Vertigo, are exceedingly minute. *P. antivertigo* has the aperture of the shell so barred by long calcareous processes (*denticles*) that it is a wonder how the animal can emerge from it. Clausilia is somewhat similar to Pupa, but longer both actually and in proportion to the width; the aperture is turned to the left (*sinistral*) instead of to the right (as is the case with the majority of snails), and is provided with a very curious spiral, shelly plate (*clausium*). A south European snail (*Stenogyra decollata*) is of a cylindrical shape, and sheds its upper whorls when it becomes adult, the aperture so formed being covered by a shelly plate. Adult specimens thus appear truncate, presenting a very singular appearance. See Rimmer's *Land and Fresh-water Shells of the British Islands* (1880).

'Darts' of Snails:
a, Helix aspersa; b, Helix arbustorum.

Snake Bird. See Darter, Wry-neck.

Snake River, the largest affluent of the Columbia River, rises among the Rocky Mountains near the western border of Wyoming, sweeps in a rough semicircle through southern Idaho, forming here the famous Shoshone Falls (q.v.), and, turning north, divides Idaho from Oregon and partly from Washington. At Lewiston it turns westward, and in southern Washington, under the name of the Lewis River or Fork, joins the Columbia, after a course of some 1050 miles. It traverses a very mountainous country, flowing through deep, lava-walled cañons, and is navigable for steamboats only to Lewiston (160 miles). In Idaho its waters are of value to the herds on the winter range. Its chief affluents are the Boisé, Owyhee, Malheur, Salmon, Clearwater, and Palouse.

Snake-root. See BISTORT, POLYGALA, ARISTOLOCHIA, and SENEGA.

Snakes (*Ophidia*) form one of the classes of reptiles, and are readily known by their shape, being limbless and much elongated. To some extent the shape may be an adaptation to the habit of creeping through crevices and among dense herbage; for, apart from snakes, it is seen in other animals which crawl through obstacles or underground, in limbless lizards (e.g. Amphisbæna and Anguis), in the amphibian Cæcilians, in various eel-like fishes, and in worms.

General Habit and Structure.—As regards habitat we distinguish tree-snakes, usually green in colour, of slender body, and of active habits; the water-snakes, including the non-poisonous freshwater forms, such as the British Grass Snake and the tropical Anaconda, and the very venomous sea-snakes (Hydrophidæ), whose flattened tail, apical nostrils, &c. are adaptations to their mode of life; the burrowing snakes (Typhlopidæ), with rigid cylindrical bodies, narrow mouths, and no specialised ventral shields; and the majority, which may be called ground-snakes.

The scales covering the body are formed from folds of skin. In each species of snake they have a definite arrangement, which is greatly relied on in the more detailed classification. This is especially true of the shields on the head, which are usually named after the underlying bones—parietals, frontals, nasals, &c.; thus between the nasal scale (on which the nostril opens) and the pre-orbital (in front of the eye) there is in harmless snakes a loreal scale, which is one of their characteristics. Most important in the life of the animal are the strong ventral scales or shields, for each of these is attached to a pair of ribs and helps to grip the ground. As they correspond in number to the vertebræ, they are also diagnostic of species. The number of vertebræ in snakes is often great, in some pythons amounting to more than four hundred. They form a uniform series, distinguishable only into pre-caudals and caudals, and all the pre-caudals except the first bear ribs. The bodies of the vertebræ are concave in front and have well-developed articular processes.

The skull is highly specialised. The bones which form the brain-case proper are firmly united, but most of the others are movable. Thus, 'when the snake opens its mouth for the purpose of striking its prey, the digastric muscle, pulling up the angle of the mandible, at the same time thrusts the distal end of the quadrate bone forward. This necessitates the pushing forward of the pterygoid, the result of which is twofold: firstly, the bending of the pterygo-palatine joint; secondly, the partial rotation of the maxillary upon its lachrymal joint, the hinder end of the maxillary being thrust downward and forward. In virtue of this rotation of the maxillary, through about a quarter of a circle, the dentigerous face of the maxilla looks downward, and even a little forward, instead of backward, and the fangs are erected in a vertical position' (Huxley). The halves of the lower jaw are connected in front by an elastic ligament, and this, combined with the mobility of the quadrates and squamosals, makes it possible for the snake to swallow its relatively large prey.

The teeth of snakes are short, conical, and sharp, and are fused to the bones which bear them. The upper teeth may occur on the maxillæ, palatines, pterygoids, and rarely on the pre-maxillæ; the lower teeth are borne as usual by the dentaries. In the most venomous snakes, such as vipers and rattlesnakes, the maxillary teeth are few, and each is folded so as to form a tubular or grooved fang. The specialised fang is connected by a gradual series of forms with the ordinary teeth.

As to the appendicular skeleton, no snake has any trace of anterior limbs or girdle, and only a few—the pythons, boas, Typhlopidæ, and Tortrices—have any rudiment of a pelvis. The pythons and Tortrices have short rudiments of hind-limbs terminated by claws.

While the nervous system of snakes differs from that of other reptiles only in small details, such as the absence of a differentiated spinal accessory or eleventh cranial nerve, the sense-organs are in many respects peculiar. The eyelids, apparently absent, are in reality fused as a transparent screen in front of the eye, as is the case in Geckos and some other lizards. The eyes are often very small, and the sense of sight seems often to be dim. As the common simile 'as deaf as an adder' suggests, the sense of hearing is also dull; there is no external ear and no tympanic cavity. The nostrils lie at the apex of the snout; the sense of smell seems sufficiently acute to guide the snakes to their prey and to their mates. In finding the latter they are aided by the peculiar, sometimes musk-like odour characteristic of snakes. Of a sense of taste they have little need, for they swallow their prey whole, nor are the usual gustatory organs present. It is not too much to say that the most developed sense-organ is the tactile tongue, with which snakes feel their way and test everything which they touch.

The internal structure of snakes presents several peculiarities in adaptation to the elongated shape of the body. Thus, the stomach is long but not broad, the lobes of the liver are also elongated, there is in most cases only one lung, the kidneys are not opposite one another, and so on. The elasticity of the food-canal is an adaptation to the swallowing of relatively large booty, and during this often slow process the larynx is shunted forward into the mouth so that respiration is not seriously impeded. Although boas, rattlesnakes, and some others have paired lungs, most snakes have only one, usually with a rudiment of the other. There are often auxiliary air-sacs on the windpipe, and the posterior part of the lung is rather a reservoir for air than an actual breathing organ. Apart from the characteristic hiss, produced by the forcible expulsion of air, most snakes are dumb, but some boas are said to whine, and a few others make peculiar sounds, of which the rattling of the rattlesnakes is best known. In having a three-chambered heart and a circulation of mixed blood in the greater part of the body snakes resemble lizards and tortoises. No urinary bladder is developed.

The Poison-apparatus.—The poison-gland characteristic of the venomous snakes is not a new structure, but merely a specialised salivary gland, and it is interesting to notice that a similar modification occurs in the poisonous Mexican lizard Heloderma. From the gland, which lies on each side behind the eye, and is about the size of an almond in the cobra, a duct extends to the base of the fang, down which the venomous juice flows when the snake bites its victim. The fangs are folded teeth, each an open groove, as in the sea-snakes, or a closed tube, as in the vipers. It is of course clearly to be understood that the 'sting of the serpent' is a poisonous bite. Stretching over the poison-gland is the membranous origin of the masseter muscle which works the lower jaw, and by means of this and other somewhat complex arrangements the poison-gland is automatically compressed when the snake opens its mouth to strike. But the opening of the mouth also brings about the erection of the fangs, which are recumbent and ensheathed when not in use. Behind each functional fang is a series of reserve fangs, and if a fang be broken the foremost of the reserves is shunted forward, and becoming fixed to the maxilla replaces the one which has been lost.

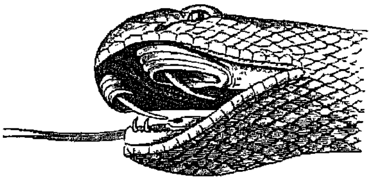

Fig. 1.

Open mouth of a venomous snake, showing the fangs half-hidden in their sheaths. (After Nuhn.)

The juice formed in the specialised glands and forced out along the fangs is a clear viscid fluid with an acid reaction, and with poisonous properties which vary according to the species and also with the vigour of the snake. It may be kept for months or even years without losing its virulence. Injected through the fangs into the blood of a victim, it tends to paralyse the nerve-centres. It has most effect on birds and mammals, less on cold-blooded animals, such as fishes. An injection of the blood of a venomous snake may also prove fatal. Several venomous snakes are unaffected by their own venom, and Fayrer states that Cobras and Daboias may bite one another with impunity. He also notices that the 'sweepers and Dhomes' who attended his elaborate experiments in India were wont to eat the animals which had been fatally bitten. In 1843 Lucien Bonaparte discovered in the poison of the adder (*Pelias berus*) a substance which he called 'viperine,' but this seems practically identical with the ptyaline of ordinary saliva, and we are still far from understanding why the juice of the poison-gland should have its peculiar properties.

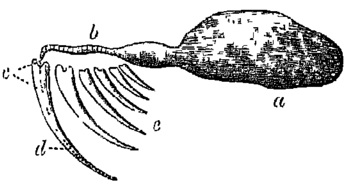

Fig. 2.

Dissection showing the poison-gland, *a*; its duct, *b*; the tubular fang, *c*, *d*; the reserve fangs, *e*. (After Nuhn.)

Food.—Snakes are almost always carnivorous; and, as is suggested by the nature of their teeth, which are not adapted for mastication, they swallow their booty intact. Mammals, birds, reptiles, amphibians, fishes, molluscs, and insects are all eaten by snakes, and there are many forms with strange preferences—e.g. for milk and eggs. In the egg-eating African snake—Rachiodon—the teeth are rudimentary, but the inferior spines of the anterior vertebræ project on the dorsal wall of the gullet and break the egg-shells. In many cases the prey is relatively large—larger indeed than the normal size of the mouth and gullet—and the process of swallowing is tedious. In the python, for instance, there is a slow continuous action of jaws and teeth; the victim is firmly held by one side of the mouth while the other side is protruded and its teeth implanted further forward, and so on alternately on each side. Meanwhile the mobile bones of the skull are being stretched to the utmost, and the victim is covered with saliva which makes the passage down the elastic gullet somewhat easier. After a heavy meal the snake often lies dormant for a time, after which it may cast its slough.

Movements.—Owen has said of snakes that they can 'outclimb the monkey, outswim the fish, outleap the zebra, outwrestle the athlete, and crush the tiger;' yet all without limbs. The muscular system is very strongly developed, and the long ribs associated with most of the vertebræ serve instead of legs. The serpent 'literally rows on the earth, with every scale for an oar; it bites the dust with the ridges of its body.' On a very smooth surface—on glass, for instance—it can make no headway, but in normal conditions the edges of the anterior ventral scales are fixed against the roughnesses of the ground, the ribs are drawn together first on one side then on the other, the body is thus wriggled forward to the place of attachment, the hind part fixes itself, the front part shoots out, an anterior attachment is again effected, and thus the snake glides onwards. But this scarcely suggests the swiftness or the beauty of what Ruskin calls 'one soundless, causeless march of sequent rings, and spectral procession of spotted dust, with dissolution in its fangs, dislocation in its coils. Startle it; the winding stream will become a twisted arrow; the wave of poisoned life will lash through the grass like a cast lance.' Were it not for many fanciful pictures it would scarcely be necessary to say that without any support snakes are not able to raise the anterior part of their body more than a short distance from the ground.

Sloughing.—It is well known that a snake periodically 'casts its skin,' leaving behind it a continuous 'slough.' The same process occurs in lizards, and to a less extent in some other animals. What is cast is the external layer of the epidermis, and its continuity depends on the fact that the scales are simply folds of skin. As to the physiology of the process, although a complete explanation has not yet been given, it is evident that the outer layer of the skin tends to die away, and that the continued growth of the animal makes sloughing necessary. The number of sloughings in a year varies with the species of snake and also with the age and health of the individual. Cobras have been observed to slough as often as once a month, but this seems to be unusually often. Before sloughing snakes are often almost blinded by the change in the skin over the eyes, and at this time they are said to be very irritable. In getting rid of its slough the snake gets its head free first, and the outer layer is turned inside out from before backwards.

Reproduction.—The sexes are almost always quite like one another externally, save that the females are always larger. The internal organs of reproduction are paired, but those of the right side are often the larger and lie in front of those on the left. The male has a double copulatory organ, sometimes covered with spines or hooks. The eggs, fertilised within the oviducts, are more or less oblong in shape, and are surrounded by a leathery envelope, 'for the rupture of which the embryos are provided with an egg-tooth, a special development like that of the chick.' Most snakes are oviparous, but, as among lizards, viviparous forms occur, such as the British Adder (*Pelias* or *Vipera berus*). It is said that Geoffroy Saint-Hilaire and Florent Prévost 'succeeded in making the (normally oviparous) Common Grass Snake viviparous by depriving it of water and maintaining a suitable surrounding temperature;' and it may be that some viperine snakes and the *Boa Constrictor*, which have borne their young alive in captivity, are oviparous in natural conditions of life. Of the python it is recorded that the mother coils herself around the laid eggs and broods over them, the temperature within the coils rising as high as 96° F.

Classification.—Snakes may be thus classified :

SUB-ORDER I.—Opoterodontia (=Typhlopidæ): the simplest and smallest snakes, sometimes smaller than earthworms, occurring in most warm countries as burrowers in the soil. The mouth is narrow and not distensible; the eyes are small and half-hidden; and the skull, besides being much less mobile in its parts than is usual in snakes, is unique in having transverse palatine bones which meet or nearly meet in the base, in the absence of a 'transverse bone,' and in the freedom of the pterygoids from the quadrate; only one jaw, either the upper or the lower, bears teeth. They are not venomous. Most of the forms belong to the genus Typhlops—represented in America, Africa, India, Australia, and by one species in south-eastern Europe.

SUB-ORDER II.—Colubriformia: mostly harmless snakes without any fangs (Aglyphodontia), or with some of the posterior maxillary teeth grooved and fang-like (Opisthoglyphia). Examples: the Pythons (Pythonidæ), the Boas (Boidæ), the Grass or Ringed Snake (*Tropidonotus natrix*), the Smooth Snake (*Coronella lævis*), the Tree-snakes (Dendrophidæ and Dryophidæ).

SUB-ORDER III.—Colubriformia venenosi: poisonous snakes with permanently erect fangs, succeeded by solid teeth (Proteroglyphia). Examples: Cobras (Naja), *Hamadryas* (*Ophiophagus*), Coral-snakes (Elaps), Sea-snakes (Hydrophidæ).

SUB-ORDER IV.—Viperiformes: poisonous snakes with a few erectile maxillary teeth specialised as fangs (Solenoglyphia). Examples: Vipers (Viperidæ), and Rattlesnakes (Crotalidæ).

Distribution.—The number of species is certainly above 1000 and is sometimes estimated at about 1800. They are represented in most parts of the world, abundantly in the tropics, commonly in temperate countries, dwindling towards the poles. They are absent from New Zealand and most Oceanic islands, and it is a proverbial saying that 'there are no snakes in Iceland.' In Ireland also they are unrepresented, except by casual importations.

The Grass or Ringed Snake (*Tropidonotus natrix*) and the poisonous Viper or Adder (*Pelias* or *Vipera berus*) are the two common kinds of snake found in Britain. There is indeed only one other species, the Smooth Snake (*Coronella lævis*), and this is of rare occurrence. The smooth snake and the ringed snake are non-poisonous Colubrine snakes; the viper is a small representative of a very venomous family. As the viper is discussed in a separate article, and as the smooth snake is restricted to a few parts of the south of England, we need only describe the ringed snake. It sometimes attains a length of 3 or 4 feet, is very fond of water, and feeds chiefly on frogs, small fish, young birds, mice, and other small animals. Its colours are beautiful—usually brownish gray with a green tinge above, dull pale bluish beneath. In summer it is fond of basking among the long grass; in winter it hibernates in some sheltered nook in company with several of its fellows. Unlike the adder, the ringed snake is oviparous, laying 16–20 eggs in some well-sunned spot. It is common in some parts of Britain. These three species also form the Ophidian fauna of Scandinavia, Denmark, Holland, and Belgium; but there are over a dozen other European species, of which one of the commonest is the Asp (*Vipera aspis*).

The North American Ophidia include a large number of Colubrine snakes and about a score of pit-vipers or rattlesnakes. Among the Colubrine forms are the water-snakes (Tropidonotus), the black snakes and coachwhip snakes of the genus Coluber, the pine-snakes (Pityophis), species of Elaphis, the king-snakes (Ophibolus), the ring-necked snakes (Diadophis), and so on. Besides the rattlesnakes proper (Crotalus) there are related genera, such as Ancistrodon, the copperheads and mocassins. And outside the two families of Colubridæ and Crotalidæ there are representatives of the burrowing Typhlopidæ, of the boa-like Erycidæ, and of the venomous coral-snakes (Elapidæ)—the harlequin snake (*Elaps fulvius*) being a well-known representative of the last.

The Colubridæ form the largest and most cosmopolitan of Ophidian families, being abundantly represented in all the great regions except Australia, where the venomous Elapidæ predominate. 'The tree snakes proper (Dendrophidæ) are found in all the tropical regions; the nocturnal tree-snakes (Dipsadidæ) and the arboreal whip-snakes (Dryophidæ) are also essentially tropical, but they are either wholly, or almost wholly, wanting in Australia' (Heilprin).

The Pythons and Boas are distinctively tropical snakes: the Pythons in Africa, India, Malaya, Australia; the Boas in tropical America. Among the most important venomous snakes of India are the following: the Cobra (*Naja tripudians*), the Hamadryas or Sunkerchor (*Ophiophagus elaps*), the Krait (*Bungarus cœruleus*), and the Sankni (*B. fasciatus*), various species of Callophis, the Chain Viper or 'Bora Siah Chunder' (*Daboia russellii*), *Echis carinata*, various species of Trimeresurus, and the sea-snakes (Hydrophis, &c.).

Zoological Position.—It may be granted that snakes are more nearly allied to lizards than to other living reptiles, but the affinities are not close, nor does palæontology help us much, for fossil remains of Ophidia are scarce. 'Only one species, the *Simoliophis rochebruni*, from the Upper Cretaceous deposits of the Charente, France, is known to antedate the Tertiary period.' 'Whether or not the snakes are in part the modified descendants of the extinct lacertilian Pythonomorphs, to which they seem to approximate in certain points of structure, still remains to be determined.'

Superstitions about Snakes.—As snakes fill most men with fear, which is the prolific mother of fiction, hundreds of strange superstitions surround these animals. Born from the soil, they lick the dust for their food; powerful indeed, they are killed by spiders, and cannot stand before crabs; venomous many of them, they are poisoned by human saliva, and flee from the shadow of the ash or the odour of rosemary; their maximum size has been stated at a mile. It is not surprising that many peoples should have found in the serpent 'a divine hieroglyph of the demoniac power of the earth—of the entire earthly nature,' or even a symbol of the principle of evil. 'As the bird,' Ruskin says, 'is the clothed power of the air, so this is the clothed power of the dust; as the bird is the symbol of the spirit of life, so this of the grasp and sting of death.' For serpent worship, see SERPENTS.

We cannot wonder that the ingenuity of despair should have sought out many strange antidotes to the poison of serpents. Various kinds of herbs, portions of the snake's own body, a diet of 'antipathetic' animals, spells, charms, and amulets have been often resorted to, often of course with successful results, for the bite is not always fatal, and confidence is the best of tonics; often of course uselessly when the Fates were cruel. Among the most famous, and for the most part quite useless, 'cures' for snake-bite is the application of a 'snake-stone.' Although the nature of this so-called 'stone' is sometimes kept secret by the native quacks who prepare it, the substance is often a piece of charred bone, and its only possible efficacy lies in its power of absorbing the poisoned blood from the wound to which it is applied. But the results of actual experiments with snake-stones are entirely against any belief in their virtue. The same name is sometimes given to an Ammonite (q.v.), on the idea that it is a petrified snake. Another kind of snake-stone or *adder-stone*, also called *ovum anguinum*, *adder-gem*, and *druidical bead*, was carried about as a miscellaneous charm in Britain, and was believed to have been produced by a number of adders laying their heads together and hissing till the foam produced was turned into stone. Such charms when examined have often been found to be simply ancient—possibly prehistoric—spindle-whorls. See also BEZOAR.

As a superstition we must also regard the widespread belief that snakes 'fascinate' their prey. Although many observers are convinced of this, the use of the word 'fascinate' has not been justified. No doubt snakes, having no movable eyelids, have an unusual power of steady staring; no doubt birds whose nestlings are threatened will flit anxiously about regardless of danger. In countries where venomous snakes are common, it is possible that the animals on which they prey have an inherited dread of them. It is certain that both men and animals when brought suddenly face to face with something terrible are often panic-stricken and incapable of motion; but there is no evidence that snakes have a power of fascination.

Scarcely a superstition, but rather an insufficiently confirmed opinion, is expressed in the common belief that snakes swallow their young ones when danger threatens. Were not errors of observation exceedingly common, we should be inclined to accept this strange fact, for the shelter afforded by the mouth is a convenient if somewhat hazardous one, and the young snakes might live there for some time. It is known that a few fishes and amphibians carry their young in their mouths. But the possibilities of mistake are many; thus, some snakes eat other snakes, and their bodies have often been found in the food-canals of their larger neighbours. Moreover, some snakes are viviparous, and unpractised observers might mistake the oviducts for the alimentary canal.

Serpent-charming.—This art has been practised from very ancient times in Africa and the East, and often remains from generation to generation the profession of a family. Pliny and older writers frequently describe it, and there are several allusions to it in the Old Testament Scriptures; see Exod. vii. 11, 12; Psalm lviii. 4, 5; Eccles. x. 11; Jer. viii. 17. It is sometimes practised for alleged useful purposes, since the 'charmers' are often employed to clear a house of its unwelcome snake visitors, though common report says that they are yet more successful in removing inanimate objects. For the most part, however, it is, like conjuring, a form of popular amusement. In India it is practised by several distinct classes of men, who vary in the methods and success of their art. The subject has not as yet been studied with adequate scientific precision, so that it is difficult to separate what is due to trickery and to dexterity from any residual facts which cannot be thus explained. There is no reason to believe that the charmers possess the constitutional immunity from snake-bite which they often claim, for a tragic end to their exhibitions sometimes belies their pretensions, and they usually take good care to play with snakes whose fangs or even poison-glands have been carefully removed, or even to use those which are not venomous at all. Nor can we, without further evidence, believe that the professional snake-finders have, beyond the cleverness of long experience (including an educated sense of smell), any peculiar power of discovering concealed snakes, especially since it is well known that they often use simple sleight of hand, producing snakes from within the folds of their robes, or merely discover what they themselves have previously hidden. The frequent use of a musical pipe, and the way in which the snakes seem to respond to the sounds, are facts interesting to naturalists, who believe that at least many snakes are very deaf. Experiments should be made to determine how far the rhythmical motions which often accompany the music may have any influence on the snakes. That the charmers govern their snakes by their eye is another of the vague assertions of common report; but more interesting is the ancient habit of spitting down the snake's throat, closing its mouth, laying it flat on the ground, and sending it into a cataleptic—perhaps hypnotic—state, or 'turning it into a stick.' The charmers sometimes manifest a fearlessly confident dexterity in handling intact venomous snakes, and they sometimes suffer for it.

Snake-bites.—The extent of the mortality from snake-bite among inhabitants of warm countries is rarely appreciated by those who live in conditions of relative immunity. Official statistics show that in the decade 1880–89 the deaths of persons reported from snake-bite in British India varied from 18,670 (1881) to 22,480 (1889), without taking account of 2000 or 3000 cattle annually killed by snakes. Even if we doubt whether all deaths referred to snake-bite are really due to this, whether the Cobra and its allies are not blamed for more than they are really responsible for, it is certain that the mortality from snake-bite is relatively great when compared with that which any other animals cause. We cannot, however, regard it as absolutely great, for, as British India had in 1891 a population of over 22 millions, the mortality of human beings from this cause in a maximum year does not much exceed 1 in 10,000. In the decade referred to rewards were paid for snakes destroyed to the number of from 212,776 (1880) to 578,415 (1889); but the result is less satisfactory when it is known that in some places snakes are bred in order to be killed for the premium.

The effect of a snake-bite depends, on the one hand, on the species of snake, on its vigour at the time, on the extent to which the teeth closed on the flesh of the victim, and so on; on the other hand, on the species and vigour of the organism bitten. In connection with the effects of different snake-poisons Dr A. H. Hilson divides venomous snakes into two classes: in the first, including the Cobra, Krait, Daboia, and other Indian snakes, the poisoning causes paralysis of the lower extremities and the muscles of articulation, is associated with a regular or intermitting action of the heart, with paralysis of the respiratory muscles, with persistent consciousness, with little effect on the sensory ganglia, and is unaffected by injection of ammonia into the veins; in the second class, including the common Australian poisonous snakes, the Rattlesnake, and the Indian genus Trimeresurus, the poisoning causes no paralysis or only as an adventitious symptom, is associated with failure of the heart's action, but with no impeding of respiration, with rapid obliteration of consciousness, with disordered sensory functions, and is curable by injection of ammonia into the veins and by the use of stimulants. Snake-poison is usually regarded as (*a*) a neurotic paralysing the nerve-centres, (*b*) an irritant producing inflammation, and (*c*) to some extent a septic. It acts through the circulation on the nerve-centres, and also affects the blood itself.

Fayrer summarises the treatment of snake-bite as follows: 'Apply at once a ligature, or ligatures at intervals of a few inches, as tight as you can possibly tie them; and tighten the one nearest to the wound by twisting it with a stick or other such agent. Scarify the wound, and let it bleed freely. Apply either a hot iron or live coal, or explode some gunpowder on the part; or apply either carbolic or some mineral acid, or caustic. Let the patient suck the wound whilst you are getting the cautery ready; or if any one else will run the risk, let him do it.

'If the bite be on a toe or finger, especially if the snake has been recognised as a deadly one, either completely excise, or immediately amputate at the next joint. If the bite be on another part, where a ligature cannot be applied, or, indeed, if it be on the limbs above the toes or fingers, cut the part out at once completely.

'Let the patient be quiet. Do not fatigue him by exertion. When, or even before, symptoms of poisoning make their appearance, give the ammoniacal preparation called eau-de-luce, or liquor ammoniæ, or carbonate of ammonia, or even better than these, hot spirits and water. There is no occasion to intoxicate the person, but give it freely, and at frequent intervals. If he become low apply sinapisms and hot bottles, galvanism or electro-magnetism over the heart and diaphragm. Cold douches may also be useful. If the respiration be failing, artificial Respiration (q.v.), by the Marshall Hall or Sylvester method, may be employed.

'The antidotes, in addition, may be used by those who have faith in them; but, as I have said, I fear there is no reason to believe that they are of any use. Encourage and cheer the patient as much as possible. As to local effects, if there be great pain, anodynes may be applied or administered, and antiseptic poultices to remove sloughs; collections of matter must be opened. Other symptoms are to be treated on general surgical principles. This, I believe, is the sum and substance of what we can do in snake bite. If the person be not thoroughly poisoned we may help him to recover. If he be badly bitten by one of the more deadly snakes we can do no more.'

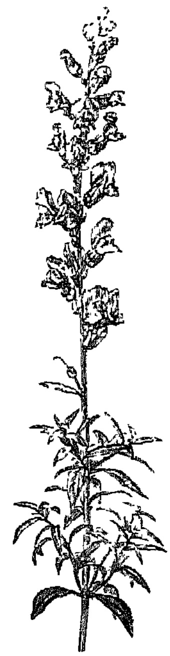
Into the debated question of the value of antidotes we cannot enter here. Nearly every drug in or out of the Pharmacopœia has been recommended; most reliance has been placed on ammonia, permanganate of potash, arsenic, iodine, bromine, the poison and bile of other snakes, the guaco plant. ipecacuanha, aristolochia, senega; but that an experienced authority like Sir Joseph Fayrer has no faith in them is comment enough. Of course it is quite possible, or indeed likely, that some toxic directly antagonistic to snake-poison will in the course of time be discovered.

Uses of Snakes.—Some snakes—e.g. Ophiophagus—eat one another; many help to keep down the numbers of small animals, such as rats and mice, whose increase is disadvantageous. Several are used for food; the poison is sometimes used by native physicians as a medicine—'a promoter of the virtue of other drugs, an anti-spasmodic, a digestive, a stimulant,' &c.; it is also used to increase the deadliness of weapons. The oil extracted from the abundant fat of many snakes is said to be very useful for external application, and there is hardly a part of the body from which it has not been employed in superstitious therapeutics.

See Anaconda, Boa, Cobra, Python, Rattlesnake, Viper, &c.; Hoffmann's 'Reptilia' in Bronn's *Thierreich* (Leip. and Heidelberg, 1859 *et seq.*); Duméril and Bibron, *Erpétologie Générale* (9 vols. A popular book with much interesting information is C. C. Hopley's *Snakes* (New York, 1882).

Snakewood. See Bread-nut.

Snapdragon (*Antirrhinum*), a genus of plants of the natural order Scrophulariaceæ, consisting of annual and perennial herbaceous plants, chiefly natives of the temperate parts of the northern hemisphere. They have the calyx five-parted; the corolla swollen at the base, but without a spur, and *personate* (Lat. *persona*, 'a mask')—i.e. its mouth closed by the pressure of the lower against the upper lip; and the fruit is a two-celled oblique capsule, opening by three pores at the apex. The English name refers to a peculiarity of the corolla, the lower lip of which, if forcibly parted from the upper so as to open the mouth, shuts with an elastic spring or snap. Some of the species have very pretty flowers. *A. majus* has long been a favourite in British gardens, in which there are many fine varieties of it. The whole plant is bitter. An oil is extracted in Persia from the very abundant seeds, by heating and then submitting them to pressure.—*Snapdragon* is also the name for a Christmas pastime in which raisins are snatched out of a dish in which brandy is burning, in a room otherwise dark.



Snapdragon (*Antirrhinum majus*).

Snaphaunce, a term originally applied to the spring-lock of a gun or pistol, but afterwards applied to the gun itself, a Dutch firelock of the 17th century. See Fire-arms.

Sneck, a town in the Netherlands, province Friesland, 13 miles SW. of Leeuwarden, with an active trade in agricultural produce, especially in butter and cheese. Pop. 11,465.

Sneezing consists in a sudden violent expiration, preceded by one or more inspirations. During the expiration the fauces are generally closed so as to direct the current of air through the nose. Sneezing is most frequently produced by the presence of irritating substances in the nose, and indeed its purpose seems to be mainly to expel these from the nasal cavities. Irritants stimulate the terminal branches of the fifth nerve which are distributed over the nasal mucous membrane, and the stimulus conveyed to the 'respiratory centre' in the medulla leads to the respiratory efforts described. Sneezing is therefore a 'reflex act,' and as such is beyond the control of the will. It may, however, sometimes be prevented by the application of a strong stimulus to the nasal nerve, such as by compressing it at its exit from the nose, and it may also be prevented sometimes if a bet be made that it will take place. Sneezing may also be induced by irritation of other nerves than the nasal: thus, by gazing at a very bright light the strong stimulation of the optic nerves will sometimes bring on a sneeze. Sneezing not only rids the nasal cavity of foreign substances, but acts in a special way upon the general and especially the cerebral circulation. For the respiratory centre in the medulla is in close proximity to the vaso-motor centre, and the stimulus which leads to the sneeze produces at the same time increased activity of the vaso-motor centre, whereby the pulse is quickened, the blood-pressure rises, and the blood-vessels of the brain are dilated. Hence sneezing exerts a stimulant effect on the brain. Substances employed to induce sneezing are termed 'sternutatories' or 'errhines,' the principal ones being snuff, ipecacuanha, and euphorbium.

Paroxysmal sneezing is an expression of a special idiosyncrasy, and occurs most frequently, if not always, in persons of nervous habit. The attacks are often periodic, recurring like '*morning-sneezing*' with great regularity at certain times or under certain conditions. In others the attacks are provoked by the inhalation of dust or by particular odours. All these forms of morbid sneezing are due either to an increased irritability of the nerves in, or to chronic congestion of, the nasal mucous membrane, or to an increased excitability of the central nervous system, or to both, and they are largely maintained by *habit*. The disease is not infrequent in persons of gouty or asthmatical tendencies. The treatment consists in the choice of a climate most suitable to the individual, but no rule can be laid down for any one case; in some cases change of air appears to exert little influence, in others a change even to the opposite side of a street will effect a cure. Diversion of the attention will often prevent the appearance of a paroxysm at its wonted time. The drugs employed most successfully in combating the affection are opium, morphine, the combined bromides or iodides of sodium, potassium, and ammonium, *Lobelia inflata*, and nervine tonics. Locally, snuffs composed of iodol and gum acacia, or containing morphine, cocaine, or bismuth are useful. See also HAY-FEVER.—The custom of formally invoking a divine blessing on one who has just sneezed is of venerable antiquity, and is very widely spread, but its real significance is by no means so easy to determine. Rabbinical legends connect it with Jacob, but it is not possible to give any fuller answer to Pliny's question, 'Cur sternumentis salutamus?' than to say that it expresses respect to a divine intimation or to a natural sign of mortality. The most famous historical sneeze is that which was hailed as a good omen by Xenophon's ten thousand at a moment of despair.

Sneeze-wood (*Pteroxylon utile;* nat. order Sapindaceæ), one of the largest and most valuable trees in Cape Colony, sometimes yielding logs 80 feet long by 4 feet in diameter. The wood is of a yellowish colour, and has a handsome appearance somewhat resembling satinwood in the grain. It is difficult to work owing to its great hardness, but is believed to be very durable. It is employed for cabinet-making, for carpentry work, and for engineering purposes. Neither the white ant nor the teredo, it is said, will penetrate it. Its native name is *Umtati*, and it derives its English name (a translation of the Dutch *Nies-hout*) from the irritating nature of the dust which results from sawing or otherwise working it, and which causes sneezing.

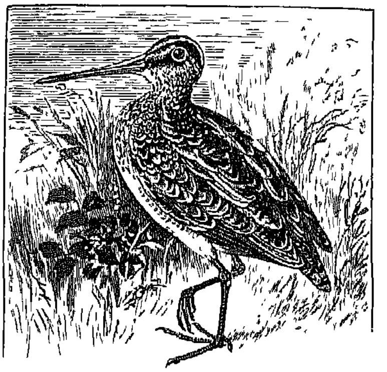
Snehætten, a mountain of the Dovrefjeld (q.v.) in Norway, 7566 feet high.

Snell Exhibitions. See GLASGOW (UNIVERSITY), Vol. V. p. 236.

Sniatyn, a town of Austrian Galicia, on the Pruth, 25 miles NW. of Carlowitz. Pop. 10,832.

Snider, JACOB, the inventor of a method for converting Enfield muzzle-loading rifles into breechloaders (see BREECH-LOADING, and RIFLES). Originally a Philadelphia wine-merchant, he busied himself in inventions connected with dyeing, brewing, coach-wheels, the sheathing of ships, &c., and crossed to England in 1859 to induce the British government to adopt his system of breech-loading or converting. In this he succeeded, but for one reason or another found himself unable to obtain the expected remuneration. He died 25th October 1866, without having received the reward of his labours, worn out by delays, lawsuits, poverty, and debts.

Snipe, the name of a genus (Gallinago) and of a family (Scolopacidæ, q.v.) of birds, order Grallæ. The birds of this genus, which has been separated from the genus Scolopax of Linnæus, have a very long, straight, flexible bill, slightly elevated towards the tip of the upper mandible, which expands a little, is decurved at the point, and projects over the lower. The whole bill is smooth, soft, and extremely sensitive. The head is compressed; the eyes are large and are placed far back. The wings are moderate in size; the legs are rather long; the three toes in front are long, slender, and divided to the base; the hind-toe is slender. The Common Snipe (*G. cœlestis, media,* or *scolopacina*) is about 11 inches in entire length, the bill almost 3 inches.



Common Snipe (*Gallinago cœlestis*).

The sexes are alike in plumage, but the female is rather larger than the male. The general colour of the upper parts is blackish brown, finely mixed with pale brown and with a rich buff colour; three pale brown streaks along the head; the neck and breast pale rust colour mottled with black; the belly white. The tail consists of fourteen feathers. The snipe when flushed changes its course several times in a zigzag manner in the air, and then darts off very swiftly, so that young sportsmen find it a very difficult bird to shoot. The snipe makes a very inartificial nest of a little dry herbage in a depression of the ground, or sometimes in a tuft of grass or rushes. The eggs are four in number, large for the size of the bird, pale yellowish or greenish white, the larger end spotted with brown. This species of snipe is plentiful in all the moory and marshy parts of Britain, and generally throughout Europe and as far as Iceland, also extensively in Asia, and it is found in the north of Africa, its representative in South Africa being a distinct species (*G. æquatorialis*). It breeds in Britain, even in the south of England, and migrates in autumn, to return in the following spring, while the winter birds are migrants from Scandinavia, arriving in the end of summer and departing in spring. The note of the snipe is a *scape, scape;* but during the breeding season the bird emits a peculiar drumming or bleating sound (hence the name 'heather-bleater' given to the snipe in Scotland) when executing its extraordinary aerial evolutions. The origin of this sound has been much disputed. The snipe is capable of being tamed, and becomes very familiar, but is difficult to keep, from the prodigious quantity of worms and other such food which it requires. A tame snipe has been known to eat nearly twice its own weight of worms in twelve hours. The snipe is in high esteem for the table, and is included amongst game in Britain. The habits of all the other species of snipe correspond very nearly with those of the common snipe. The Great Snipe, or Solitary Snipe (*G. major*), an annual visitor in small numbers to eastern and southern parts of England, very rare in Scotland and Ireland, but abounding in the extensive marshes of continental Europe, is found also in Asia and in many parts of Africa. Its entire length is about 12½ inches, the bill not quite so long in proportion as that of the common snipe. There are sixteen feathers in the tail. The Jack Snipe, or Judcock (*G. gallinula*), the smallest and most beautifully coloured of the group, is like the common snipe in plumage. It is common in Britain, but mostly as a winter visitant, and is found also during summer and winter in most parts of Europe and of the north of Asia and in North Africa. North America has a number of species. The Common American Snipe (*S.* or *G. wilsoni*) is about equal in size to the common snipe of Europe, and much resembles it also in plumage, but has sixteen feathers in its tail. The name snipe is extended in popular usage to include the genus Macrorhamphus, in which the outer toes are connected at the base by a membrane. In other characters, as well as in plumage and habits, the similarity to the true snipes is very great. The Red-breasted Snipe, or Brown Snipe (*M. griseus*), of North America has been occasionally seen in Britain and in Picardy and Normandy. In size it is nearly equal to the common snipe.

Snipe-fish. See TRUMPET-FISH.

Snizort, LOCH, a large and picturesque inlet of the sea in the north-west of Skye, between Trotternish and Vaternish Points. It narrows from 9 to 3¾ miles, and is 8½ miles long.

Snoring, an abnormal and noisy mode of respiration produced by deep inspirations and expirations through the nose and open mouth, the noise being caused by the vibrations of the soft palate and uvula. Sometimes the noise arises in the glottis, the vocal chords vibrating loosely. Keeping the mouth shut will usually make snoring impracticable.

Snorri Sturlason, an Icelandic historian and politician, was the son of a chief of the western fjords, and was born in 1179. The grandson of Sæmund Sigfusson, the compiler of the Elder or Poetic Edda, instructed him in the history, mythology, and poetry of the North, as well as in classical literature. By a wealthy marriage Snorri early sprang into a position of influence, and was elected (1215) supreme judge as well as president of the legislative assembly of the island. But his ambition, avarice, and love of intrigue led him to take part not only in private quarrels, but in the intestine troubles of Norway, and thus drew upon him the ill will of the Norwegian king, Hakon, who sent secret instructions to Iceland for his arrest, or, if need be, his assassination. The king's commands were carried out by one of Snorri's bitter enemies, who attacked him in his own house, and murdered him in the year 1241. Snorri was a poet of no mean order; and besides numerous laudatory poems on contemporary kings and jarls, he composed the Younger or Prose *Edda* (q.v.) and the *Heimskringla*; this last is a series of sagas or biographies of the Norwegian kings down to 1177, based on trustworthy sources and critically sifted evidence, and is written in a lively and interesting style. It has been translated by S. Laing (1844; new ed. by Rasmus B. Anderson in 4 vols. 1889).

Snow is the crystalline form into which the excess of vapour in the atmosphere is condensed when the temperature is below freezing. It is not, like hail or sleet, frozen rain, but is formed directly by the invisible aqueous vapour condensing in minute spicules of ice round the dust-particles that float in the air. More than 1000 different forms of crystals have been observed, and many of the chief or typical forms sketched by Scoresby, Glaisher, Kaemtz, and others; but in all of them the filaments of ice are arranged at angles of 60° or 120°, and they may be grouped into five classes. (1) Thin plates or stars of six rays (figs. 1 to 5), the forms getting more complex the lower the temperature. (2) A solid nucleus or a flat plate, with needle-like crystals projecting in all directions: fig. 7 is a section through one of these. (3) Fine hexagonal or three-sided prisms about ⅓th of an inch long. (4) Prisms having thin plates perpendicular to their length: this form is rare (fig. 6). (5) Pyramids with six faces (fig. 8): this form also is rare, and is often associated with electrical disturbances. Each shower generally consists of flakes of one class only. Their form is best seen in calm weather; if there is much wind the crystals are broken and irregular, and during gales tend to agglomerate in spherical masses. The size of flakes varies from about an inch down to $\frac{1}{10}$th of an inch in diameter, the size being smaller the lower the temperature, but isolated crystals occasionally fall in calm cold weather. The snow-fall of the British Isles is rarely so great as to cause serious inconvenience, except when accompanied by wind and consequent drifting; it then accumulates in railway cuttings and other sheltered places very rapidly, and to an extent limited only by the depth of the sheltered place. In the New England states the average annual fall ranges from 4 to 7 feet. In the Arctic regions and Siberia, though the fall is not greater than this, the snow lies unmelted much longer. To the south of lat. 40° snow is rare, except on hills; but it has been known to fall and lie for several days in Algeria and Morocco; and at Canton, within the torrid zone, it has fallen to

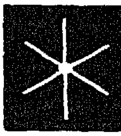


Fig. 1.

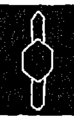

Fig. 7.

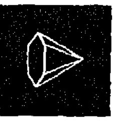

Fig. 8.

a depth of 4 inches. Fresh-fallen snow is very light, owing to its looseness of structure—a foot of such snow gives only about an inch of water when melted; but it increases in density when lying, partly by compression due to its own weight, partly by the filling of the interstices with condensed and frozen moisture from the air, and greatly by partial thawing and refreezing. In this way the snow on mountains that rise to a height sufficient to have a temperature mostly below freezing gets hardened into *névé*, and ultimately into the ice of the glacier, by which it is transferred to lower regions; but if the depth on a steep slope gets too great before it has time to harden it is liable to sweep down suddenly as an avalanche of dry snow. On the other hand, the sudden melting of snow may cause dangerous floods, such as occur when the warm wind, called the Föhn, blows over the Alps; but the more gradual melting of the snow-mantle of hills feeds the deep-seated springs of rivers. The flooding of the Nile, the source of the fertility of Egypt, is due to snow melting on the mountains of Central Africa. The snow of the Arctic regions, where solar radiation is weak, does not compact together, but remains dry and powdery; in eastern Siberia the prevalent wind is north-west, and all winter there is a continual drift of dry snow along the surface towards the south-east. The white colour of snow is due to reflection of the light from the innumerable surfaces of the crystals, each of which is composed of clear ice, just as glass loses its transparency when pulverised. Snow is feebly phosphorescent, absorbing light during the day and giving it out at night. The loose texture of freshly fallen snow makes it an admirable non-conductor of heat, and in the temperate zone it often preserves the ground from the chilling action of short spells of intense cold. The latent heat set free when vapour condenses into snow also sometimes mitigates the severity of a frost.

Snow is sometimes, in polar and alpine regions, where it lies unmelted from year to year, and the annual fall is small, coloured red by the presence of innumerable small red plants. In its native state the plant consists of brilliant red globules seated on a gelatinous mass. It is an Alga, and is now known as *Protococcus nivalis*; it is probably near akin to the not uncommon *Hæmatococcus pluvialis*. Red snow seems to have been observed by the ancients, as a passage in Aristotle apparently refers to it; but it attracted no attention in modern times till 1760, when Saussure observed it in the Alps, and from chemical experiments concluded that the red colour was owing to the presence of some vegetable substance, which he supposed might be the pollen of a plant. The next observations on red snow were made in the Arctic expedition under Captain Ross, when it was found extending over a range of cliffs on the shore of Baffin Bay for 8 miles, and the red colour penetrating the snow in some places to a depth of 12 feet. Less frequent is a green growth on snow. See also BACTERIA, BLIZZARD, ICE.

SNOW-LINE.—This is the usual term employed to signify the height below which all the snow that falls during the year is melted in the course of the summer, or, in other words, the limit above which snow perpetually lies. It is no hard and fast line, but varies greatly in different localities, and in most localities varies more or less from year to year. Hence it would be more appropriate to speak of a zone, having superior (upper) and inferior (lower) limits, within which the snow-line moves up and down. The altitude at which this line (or zone) falls depends upon several conditions —viz. the volume or quantity of snow precipitated during the winter, the amount of the rainfall and the position of the mountain-slope with reference to the principal rain-bringing winds, the latitude or distance from the equator, the degree of exposure to the sun's rays, the angle of the slope or the relative steepness of the mountain-side, and the general humidity or dryness of the atmosphere. Other things being equal, the following rules hold good: the snow-line is higher in north latitudes on the south than on the north side of mountains; higher on the east than on the west, owing to the greater prevalence of westerly winds in regions where snow accumulates; and higher in the interior of continents than near the sea, because in the former situations the precipitation is less and the heat of summer greater. In each separate locality the snow-line must be determined by a proper series of observations. To the general rules quoted above must be superadded those that depend upon the latitude: between 20° N. and 20° S. of the equator the altitude is pretty uniform; from 20° to 70° on both sides of the same central girdle it falls as the latitude increases in a pretty regular manner; but beyond 70° N. and S. and up to 78° in both directions it sinks very rapidly.

To these general rules there are of course in actual fact some important exceptions. In the Himalaya the snow-line runs 4000 feet higher on the north than it does on the south side; this is caused by the greater depth of snow that falls on the south side, by the greater dryness of the climate of Tibet, which increases the evaporation and consequently the heating power of the sun's rays, and by the comparatively treeless rocks and barren soil on the northern side absorbing more heat and attracting less precipitation than the well-wooded southern slopes. In the Andes the snow-line rises very rapidly between the equator and 18° S. lat., and more rapidly in proportion on the west than on the east side, owing to the comparatively small quantity of snow that falls on the Pacific side of the mountains. The subjoined table gives the snow-line on some of the most important mountain-ranges and peaks on the globe.

Mountains.	Latitude.	Snow-line in feet.

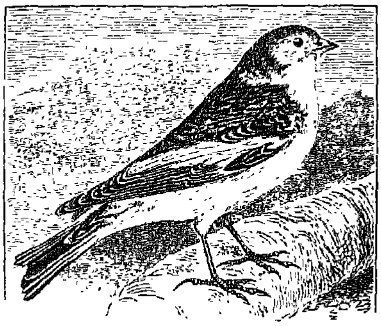
Snowball Tree. See GUELDER ROSE.

Snowberry (*Symphoricarpos* or *Symphoria racemosa*), a bushy deciduous shrub of the natural order Caprifoliaceæ, a native of the northern parts of North America, and now very common in British shrubberies. It has simple leaves, small flowers, and white uneatable berries about the size of black currants, remaining on the bush after the leaves. The name is also given to *Gaultheria serpyllifolia*, a native of North American bogs.

Snow-bird (*Fringilla hyemalis* or *hudsonia*), a North American bird of the Finch family (Fringillidæ), common from the Gulf of Mexico to the Arctic Circle, in all the eastern parts of North America. The wings are rather short, the tail slightly notched. The whole length is about six inches; the upper parts are lead-colour, the lower parts white, the two outer tail-feathers white, the next white margined with black. This bird migrates northwards early in spring, and southwards late in autumn. They are first found in small flocks; their favourite haunts are roadsides, but they always take to trees when disturbed. In cold weather they visit farmhouses and villages; and before a snowstorm they assemble in large flocks, visiting barn-yards, and hopping about with the domestic poultry and small birds. The song of the male in the breeding season consists of a few very low, sweet warbling notes. From its frequent familiar approach to human habitations, the snowbird is regarded with favour throughout great part of North America, as the Redbreast is in Britain. The name is also given to all the species of the fringilline genus Junco, including *J. hiemalis*, found both in the United States and in Canada.

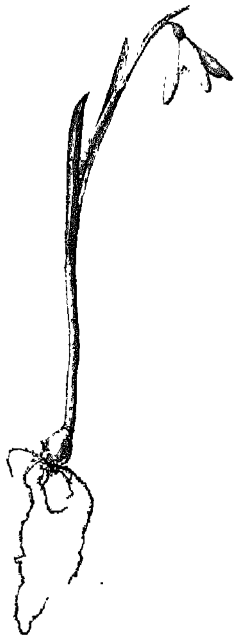
Snow-bunting, or SNOWFLECK (*Plectrophenax nivalis*), a bird of the Finch family (Fringillidæ), Bunting sub-family (Emberizinæ), abundant in summer in the Arctic regions generally, where it has been found nesting nearly as far north as man has reached; in winter migrating southwards to Georgia in North America, to Japan, northern China, Turkestan, southern Russia, the northern shores of the Mediterranean, and Morocco. In Iceland it abounds all the year round; in the Faroes it is common in winter, and many remain to breed; in the British Isles it occurs in large flocks in winter, and it has also been found nesting on high mountains in Sutherland and in the Shetlands. It is a bird about 6¼ inches long; plumage black and white; bill, legs, and feet black; but in autumn the feathers of the upper parts are broadly edged with dull chestnut, the bill is yellow with a black tip, and the bird is then known as the Tawny Bunting. In habits it differs in several respects from the true buntings: it runs rapidly on the ground, it also hops, and not infrequently perches on trees; and the song of the male while the female is on the nest is a low, melodious warble. The food in summer consists of insects, in winter of seeds. The nest, made of dry grass and moss, and lined with hair and feathers, is in northern breeding haunts placed on the ground not far above the sea-level; but in more southern latitudes it is generally built in rocks on the rugged sides of mountains. The snow-bunting is generally very fat, and is highly esteemed for the table. The Greenlanders kill great numbers, and dry them for winter use. See the article BUNTING.



Snow-bunting (*Plectrophenax nivalis*).

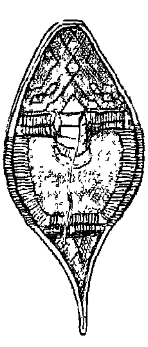
Snowdon, a mountain-range in Carnarvonshire, North Wales, stretches in a north-east-by-north direction from a point 5 miles N. of Criccieth, near the head of Cardigan Bay, to near Conway, but is broken up by valleys and river-courses into five distinct summits, the chief of which, Moel-y-Wyddfa ('conspicuous peak'), the highest mountain in south Britain, was shown by the new Ordnance map of 1889 to rise only 3560 (not 3571) feet above sea-level, and is crowned by two huts, the 'Hotel.' Seen from the top, Moel-y-Wyddfa, the 'King of Snowdonia,' appears to send out three ridges, which gradually divide and subdivide, giving birth to numerous valleys and corries. Its ascent is effected from Llanberis (on the north), Beddgelert (on the south), Snowdon Ranges station (on the west), and Capel Curig (on the east). The first is short (5 miles) and the easiest; the last the longest (9 miles) and most difficult, but at the same time by far the grandest. The district of 'Snowdonia' was made a royal forest by Edward I. of England, but was disafforested in 1649. In July 1889 Snowdon was purchased for £5750 by Sir Watkin Wynn, Bart., the 'King of Wales.'—Snowdon was also an old name for Stirling.

Snowdrop (*Galanthus*), a genus of plants of the natural order Amaryllideæ, of the same tribe with Amaryllis, Snowflake, Crinum, &c. The three outer segments of the perianth spread, so as to make a bell-shaped flower; the three inner are shorter, erect, and notched at the summit. The flowers arise from a spathe. The root is bulbous, and produces two leaves and one single-flowered leafless stem (*scape*). The Common Snowdrop (*G. nivalis*), a plant too well known to need description, is a native chiefly of the south of Europe, growing in woods and pastures. It is found apparently wild in some places both in England and Scotland, but is probably rather naturalised than native, having long been much cultivated in gardens. This welcome harbinger of spring flowers usually in Britain in February and March. Another species of snowdrop (*G. plicatus*), with much broader leaves, is found in the south of Russia and in Asiatic Turkey.



Common Snowdrop (*Galanthus nivalis*).

Snow-shoes, a species of shoe whose broad surface prevents the foot from sinking in the snow. The Canadian snow-shoe (3 to 5 feet long and 1 to 2 feet wide) presents somewhat the shape of a tennis racquet with a short handle behind and long oval body contracted in front. It consists of a light frame of tough wood supporting a web of raw hide, to which, on the widest part, the foot is fastened by thongs, which leave the heel free. The Norwegian *ski* is simply a long, narrow wooden runner (5 to 10, but usually 8 feet long, by some 4 inches wide), about 1 inch thick at the middle, but thinner towards the ends, and turned up in a curve at the front (sometimes slightly at the back also).



Snow-shoe.

Snuff. See Tobacco.

Snyders, Francis, a Flemish painter, born at Antwerp in 1579, studied under Van Breughel and Van Balen. Originally he confined himself to painting fruits, game, vegetables, and other typical models of still-life; but under the influence of Rubens, for whom, as well as for Jordaens, he frequently painted animals and still-life subjects to go in their larger pictures, he cultivated more especially the painting of animals. His bear, wolf, and boar fights have hardly ever been surpassed. He painted a stag-hunt and similar hunting subjects for Philip III. of Spain. Snyders died at Antwerp in August 1657.

Soane, Sir John, an English architect, born of humble parentage at Reading on 10th September 1753. He managed to get trained as an architect, and, having gained the travelling scholarship of the Royal Academy, spent three years (1777–80) in Italy. After his return home he secured several official appointments—e.g. architect to the Bank of England, St James's Palace, Office of Woods and Forests—and was elected professor of Architecture at the Royal Academy (1806). He designed numerous country-houses in the eastern counties and parts of public buildings (Bank of England) in London, showing in his plans considerable ingenuity, but an uncertain taste, and frequently a lack of harmony in his completed plans. At his death, in London on 20th January 1837, he bequeathed his own house in Lincoln's Inn Fields, and the valuable art and antiquarian museum it contained, including pictures by Hogarth, Reynolds, Turner, models by Flaxman, the MS. of Tasso's *Gerusalemme Liberata*, &c., to the nation. He published amongst other books a set of folio plates of *Public and Private Buildings* (1828), and a *Description* (1832) of his own house and museum.

See the Memoir by J. Britton (1834), and the *Art Journal* (1882).

Soap is the term applied to that class of compounds formed when alkalies act upon fats or fatty acids. Chemically it includes also the insoluble compounds formed from metallic oxides, as lime, litharge, &c.; but industrially it is confined to the compounds of soda and potash. Soap is first mentioned by Pliny, who states that it was prepared from goat's tallow and beech-tree ashes, and was employed for giving brilliance to the hair. The excavations at Pompeii brought to light a complete soap-making establishment, containing some well-preserved soap. The industry, however, advanced very slowly, and it is only within comparatively recent years that it has really flourished. The most important discoveries which have assisted its development and led to its present enormous proportions are Chevreul's researches on the constitution of fats and Leblanc's process for the manufacture of soda on a large scale. It has also been stimulated in Britain by the repeal in 1853 of the duty (amounting to from 1d. to 3d. per lb.), first imposed in 1711. Chevreul showed that the neutral fats are mixtures of 'glycerides,' consisting of glycerine combined with the elements of certain fatty acids. In the process of saponification the fat is decomposed, the fatty acids combining with the alkali to form soap, while the glycerine is set free.

Soaps are distinguished as 'hard' (soda-soaps) and 'soft' (potash-soaps). They have a characteristic taste, and are soluble in water and in alcohol. When agitated with water a 'lather' is produced, and when their hot aqueous solutions are allowed to cool jellies are formed. Salt precipitates them from their solutions, but in the case of a potash-soap the bulk is converted into a soda-soap by double decomposition. The cleansing power of soap has not been satisfactorily explained; it is generally supposed to be due to the 'hydrolysis,' or partial decomposition into free alkali and insoluble acid-soap which takes place when the soap is dissolved in water. Dittmar considers that the cleansing power of soap may be attributed to 'the inherent property of its solution to emulsionise fats,' which seems a more plausible theory.

The principal fats and oils employed in the manufacture of soap are tallow, greases, palm-oil, lard, cocoa-nut oil, and olive-oil for 'hard' soaps; distilled fatty acids are also used, and rosin in conjunction with tallow, &c. For 'soft' soaps linseed-oil, castor-oil, and fish-oils are used, as well as some of those already mentioned. The caustic alkalies, potash and soda, were formerly prepared from the carbonates by the soap-maker himself, but are now almost entirely procured from the soda-manufacturer.

The following processes, arranged in order of simplicity, are those used in the manufacture.

(1) The direct union of free fatty or resinous acids and alkalies.—This process is seldom used. The fatty acid (e.g. oleic) is run into a steam-jacketed pan, provided with a mechanical agitator, and raised to about 300° F. by super-heated steam. A strong solution of the necessary quantity of alkali is then added, and the whole well stirred. The mixture is allowed to stand for some time, some water added, again stirred, and removed to cooling-frames.

(2) Treatment of fats with definite quantities of alkali, the glycerine remaining with the soap; known as the 'cold process.'—Given weights of fat are melted at the lowest possible temperature, and mechanically mixed in a pan with a definite quantity of caustic lye of known strength, just sufficient to effect complete saponification. After standing for from one to four days, according to the quantity, the soap is hard enough for use. This process possesses the advantages of economy and retention of the glycerine. Soaps made in this way, however, are liable to contain free alkali, and of necessity contain also the impurities of the soda.

(3) Treatment of fats by boiling with indefinite quantities of alkaline lye.—This process is the most important of the three, and will now be described as it is carried out for 'hard soaps.'

Hard Soaps constitute the great bulk of the soaps used, and may be divided into three varieties—curd, mottled, and yellow. The general method is the same for the three. The vessel used (called the 'copper') is made of wrought-iron plates riveted together, and is provided with coils for supplying open and close steam. These 'coppers' are generally of circular form, and capable of turning out from 20 to 30 tons of soap at one operation, although some of them are much larger. In the first stage (called 'killing the goods') a quantity of the fat is melted in the 'copper,' weak caustic lye added, and the steam turned on. The mass becomes pasty after some time, and the boiling is continued, and fat and lye added, until a sample appears somewhat firm, and has very little or no caustic taste. In the second stage ('cutting the soap' or 'salting') the water is separated from the soap (the boiling being continued) by the cautious addition of common salt, or strong brine, until clear liquor runs from a small sample taken out. After standing for a few hours the 'spent lye' (containing the bulk of the glycerine of the fat, common salt, and the impurities of the caustic soda) is removed. In the third operation ('clear boiling') the granulated soap is boiled for two to three hours with fresh lye, in order to cause more complete saponification, and to remove the brine retained by the soap. After settling, the lye is removed, and may be used for the treatment of more fresh fat. The contents of the 'copper' are again boiled with open steam and lye for several hours, to complete the saponification of the last traces of fat, and 'make' the soap.

The method of finishing the soap varies with the kind of soap required, and will now be explained under the names of the three varieties.

Curd Soaps.—The finest quality is made from tallow, but other fats may be used. When the soap has been 'made,' as just explained, the lye is concentrated by means of close steam, until a sample of the soap appears hard. The *boiling* is then stopped, and the soap removed, after settling.

Mottled Soaps, as far as composition is concerned, are practically 'curd' soaps; darker fats, however, are used in their manufacture, and after the soaps have been 'made' the lye is not concentrated so far as with 'curd' soaps. Many precautions require to be observed in order to obtain the *natural* '*mottling*' which characterises them. It is due to the presence of small quantities of lime, magnesia, &c., from the materials used, and to oxide of iron, from the 'copper.' These oxides form insoluble soaps, and when the soap, retaining a little lye, is transferred to the cooling frames, they collect together, producing the well-known appearance.

Natural 'mottling' may be accepted as a guarantee of the absence of an undue amount of water in a soap. Artificial 'mottling' of inferior qualities of soap with ultramarine, oxide of iron, &c. is largely practised, sometimes with fraudulent intentions. 'Mottled' soaps are much used for laundry work and such purposes.

Yellow Soaps contain rosin as an essential constituent. The finest qualities are made from the best tallow and light-coloured rosin; inferior qualities from darker tallow, bleached palm-oil, &c., and darker rosin. The rosin is usually introduced after the second stage of the general process. The finishing operation, or 'fitting' of yellow soaps, requires much experience. After the soap has been 'made' the 'copper' is allowed to stand for about twelve hours, the lye removed, and the soap well boiled until homogeneous, with some fresh lye if necessary. When a sample has been found to be in the proper state, the 'copper' is covered up, and allowed to stand for some days, when a separation into three layers takes place—the scum or 'fob' on the top, the 'nigre' (or dark alkaline soap-lye) underneath, and the finished or 'neat' soap in the centre, which is then removed to frames. The 'nigres' are utilised in the making of darker soaps. The principal soap-manufacturers now recover the glycerine from their 'spent lyes.'

Cocoa-nut or Marine Soap.—Cocoa-nut oil is saponified in the heat, with *strong* lye, without salting out, &c. A hard soap is formed, although much water may be present, and is serviceable on board ship, when condensed water is not available, on account of its solubility in salt water.

The operations subsequent to the soap leaving the 'copper' require little explanation. When no 'filling' substances are to be added the melted soap is run, or ladled, into large oblong boxes of wood or iron, called '*cooling frames*.' After standing for several days to allow the soap to harden, the sides of the frames are removed, and the blocks of soap cut, first into slabs, by means of a thin steel wire, and then into 'bars' by a special machine, consisting generally of a strong frame or lever, carrying a number of wires stretched across it. The 'bars,' after having been stamped with the name of the maker, and the brand of the soap, are ready for being sent out.

The demand of the public for cheap soap has led to what is known as 'filling.' This consists in mechanically mixing with or 'crutching into' the soap, after it leaves the 'copper,' certain substances, added either with the view of increasing the detergent power of the soap, or simply to lessen the cost. *Silicate of soda belongs to the first class*, and is used with advantage in certain soaps. Such substances, however, as water, talc, clay, chalk, sulphate of baryta, &c. must be looked upon merely as adulterants.

Soft Soaps are really impure solutions of potash-soaps, with glycerine, in caustic lye. They form transparent jellies, and often exhibit, in cold weather, a white *graining*, or '*figging*,' *due to* alkaline stearates. The oil (e.g. linseed, or any other of those named above) is run into the 'copper,' potash lye added, and the steam turned on. The boiling is continued, latterly by close steam or fire heat, and lye added, until a small sample appears clear on cooling, and no liquid separates from it. When finished the soap is run into barrels or tins.

Toilet Soaps.—The basis or 'stock' of the better qualities is generally good curd or yellow soap, special precautions being taken to ensure absence of free alkali. The finest toilet soaps are now 'milled.' For this purpose the soap is cut into shavings, dried partially, the colouring material and perfumes added, and passed several times between granite rollers, to make it perfectly homogeneous. It is then subjected to great pressure, or 'plotted,' to form it into bars, which are afterwards cut, and stamped into tablets. The lower qualities of toilet soaps are generally made by the 'cold process.'

'Transparent' soaps are prepared by dissolving good dry soap in alcohol, pouring off the clear solution, and removing the bulk of the spirit by distillation. The remaining soap is transferred to moulds, allowed to cool, and preserved in warm chambers for several months, until it becomes quite transparent. Many transparent soaps, however, are made by the 'cold process,' their transparency being obtained by the addition of sugar. Glycerine is often added to both opaque and transparent soaps, imparting to them its characteristic emollient properties, while such substances as carbolic acid, coal-tar, eucalyptus-oil, &c. are added to soaps *intended for disinfecting* purposes.

The following table gives the average composition of some genuine soaps of English make:

	Fatty Anhydr.	Alkali (Na_2O).	Water.	Salts	Glycerine and Salts.
Curd. ...	63·21	8·44	26·76	1·59	..
Mottled ...	64·17	7 80	25·66	2·37	..
Yellow (best).....	61·95	7 07	30 45	0·53	..
Cocoa-nut .	52·65	8·55	30·03	..	8·77
Toilet ('milled')	80·06	9·56	9·11	1·27	..
Soft. . . .	40·36	(K_2O). 9·18	44·78	..	5·68

The commercial value of a soap depends upon its percentage of *fatty anhydride*. *Soap is used otherwise* than as a detergent—as a handy ointment for skin irritated by friction, as a laxative medicine, in *making* pills, liniments, and plasters, and as a test for the hardness of Water (q.v.).

See R. S. Cristiani, *Technical Treatise on Soap and Candles* (1881); W. L. Carpenter, *Soap, Candles, Lubricants, and Glycerine* (1885); A. Watt, *The Art of Soap-making* (1885; 4th ed. 1890); J. Cameron, *Soap and Candles* (Churchill's 'Technological' series, 1888); and C. F. Cross's 'Health Exhibition Lecture on Soap' (1884).

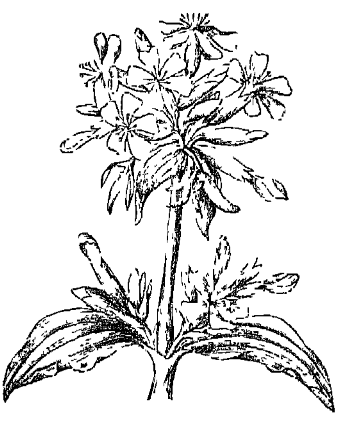
Soapberry. The fruits of several species of trees belonging to the genus Sapindus (natural order Sapindaceæ) contain a pulp which is useful as a substitute for soap in cleaning linen and other textile fabrics. In the West Indies the fruit of *Sapindus Saponaria*, and in the East Indies those of *S. emarginatus* and *S. attenuatus* are much used for this purpose. The frothy mixture which these fruits make with hot water is said to be very serviceable for cleaning dyed fabrics which soap would injure. In France silk stuffs are cleaned with the seed vessels of *S. emarginatus*. The seeds of *S. Saponaria* are made up into rosaries, and were formerly worn in England tipped with gold, silver, &c. as buttons.

Soap-bubbles. As a form of amusement for children the blowing of soap-bubbles is of great antiquity, and is to be seen depicted on an Etruscan vase in the Louvre. In their scientific aspect soap-bubbles and soap-films have been studied specially by Plateau, who, by adding glycerine in a certain proportion to the soap solution, obtained remarkably durable films and bubbles. The beautiful play of colours familiar to all is due to the excessive but variable thinness of the soap-film. It is in fact an illustration of the interference phenomenon known as Newton's Rings (see INTERFERENCE, NEWTON). If at any part the film becomes thin enough the black spot appears. If this black portion is touched the film is shattered at once, although it may in its thicker portions be pierced by a needle without losing continuity. The spherical form of the ordinary soap-bubble is a direct result of the action of Surface-tension (q.v.), the geometrical condition being that with given volume the surface must have minimum area. With soap-films formed on frames of wire the same principle holds—for given boundary and given internal volume the area must be a minimum. Thus, by a skilful arrangement of soap-films, we may make visible many highly interesting problems in pure mathematics. See *Soap-bubbles*, by Professor Boys (S.P.C.K., 1890).

Soap-stone. See STEATITE.

Soap-tree. See SOAPBERRY.

Soapwort (*Saponaria*), a genus of plants of the natural order Caryophyllaceæ, having a cylindrical or ventricose five-toothed calyx, without any outer calyx or attendant bracteæ, five undivided petals with long claws, ten stamens, two stigmas, and a capsule opening at the top by four valves. Some of the species have very beautiful flowers. *S. calabrica* is one of the most favourite annuals of British flower-gardens. Common Soapwort (*S. officinalis*) is found on waysides, in thickets, and on the banks of streams in most parts of Europe, although it is a somewhat doubtful native of Britain. Both the root and the leaves contain Saponin (q.v.), in consequence of which they are sometimes employed for washing. The brownish-red colour of the bark of the root, however, is apt to tinge white articles. The root of this plant has also medicinal properties, being aperient, resolvent, and alterative. It is sometimes sold as Red Soap-root.



Soapwort (*Saponaria officinalis*).

Nearly allied to the genus Saponaria is the genus Gypsophila, some species of which are called Soap-root, and contain much saponin. Thus, the Egyptian Soap-root (*G. struthium*), and the Spanish Soap-root (*G. hispanica*), called *Jabonera* in Spain, have been employed for washing from time immemorial, and the roots, not having a dark rind, can be used for washing white articles, and are to some extent an article of commerce, being used for silken and other stuffs, the colours of which will not bear the application of soap. The roots of *Lychnis dioica*, one of the most common British plants, possess the same properties in an inferior degree. The bark of *Quillaja saponaria*, a Chilian tree of the natural order Rosaceæ, contains much saponin, is generally used for washing in Chili and Peru, and there forms a considerable article of commerce. It is said to give a remarkable lustre to wool, and to be an invigorating wash for the hair. Some of the tropical South Sea Islands produce a species of vine (*Vitis saponaria*), the stem of which, especially the thicker part, cut into pieces, and softened by cooking on hot stones, produces in water a rich lather almost equal to that of soap. See also SOLANUM.

Sobat, a tributary of the Nile (q.v.).

Sobbing is merely a modification of the ordinary movements of respiration excited by mental emotions. It is the consequence of a series of short convulsive contractions of the diaphragm, and is usually accompanied by a closure of the glottis, preventing the entrance of air into the lungs.

Sobieski, the surname of JOHN III., king of Poland, one of the greatest soldiers of the 17th century, was born at Olesko in Galicia on 2d June 1624, his father being castellan of Cracow. He early distinguished himself in the wars in which Poland was at that period almost constantly engaged, against the Russians, the Tartars, and the Turks. Upon the last he inflicted crushing defeats at Buczacz (in Galicia) in 1669, and at Choczim (Khotin) on 11th November 1673, capturing the green standard of Hussein Pasha, commander of the Turks, and slaying more than 20,000 of his soldiers. In the next year he was chosen king of Poland. A high-minded, brave, and disinterested man, and a shrewd statesman, he conceived it to be his special mission to contend with all his energy and power against the enemy of Christendom that threatened from the shores of the Bosporus. He again routed the Turks at Lemberg in August 1675, and in 1676 successfully defied their utmost efforts to storm his entrenched camp near the Dniester. After a truce of five years—a breathing-time employed by the sultan to gather fresh armies and war material—the Turks once more overran Hungary, and even laid siege to Vienna. Sobieski, always swift in his marches, and vigorous and determined in his attacks, hastened to its relief at the head of 18,000 Poles. With these, and 50,000 German troops, who joined him on the way, he smote the 100,000 men of the Turkish commander so terribly, on 12th September 1683, that the siege was at once raised and the Turks hastened to retire. Sobieski died at his castle of Willamow on 17th June 1696. This prince was a lover of books and of knowledge, and himself a clever linguist.

See his Letters to his wife (French trans. 1826); Salvandy, *Histoire du Roi Jean Sobieski* (Paris, 1876); and an article by Lady Verney in the *Contemporary* (1876).

Sobral, a town of Brazil, in the province of Ceara, on the Aracaty, 78 miles by rail SSW. of the seaport Camossin. Pop. 10,500.

Sobraon, a village of the Punjab, on the west bank of the Sutlej, opposite which, on the east bank, was fought on 10th February 1846 a most obstinate battle between the British under Sir Hugh Gough and the Sikhs (q.v.), which put an end to the first Sikh war. Pop. 4000.

Socialism. As opinion is still so much divided regarding the significance and tendency of socialism, it would not be advisable to attempt a preliminary definition of the word. According to Mr Holyoake (in his *History of Co-operation*), the word originated in 1835 in connection with the Association of all Classes of all Nations, founded in that year by the socialist Robert Owen. The name laid special emphasis on the necessity for social reconstruction and renovation, as contrasted with the political reforms which were then so much agitated, and was therefore soon adopted as suitable and distinctive. It was borrowed by Reybaud, an eminent French writer, in his *Reformateurs Modernes* (1839), and gained a wide currency on the European continent; and it is now the recognised name for a movement which has affected almost every country of the civilised world.

In this article our chief aim obviously is to expound socialism as a historical phenomenon or set of phenomena. But even in this sphere the task is not without its difficulties, as there is little agreement even with regard to the historical application of the word. The application of words is determined by use and wont, and it cannot be said that we yet have anything like a settled use and wont to guide us in this matter. And the difficulty is greatly aggravated by the fact that socialism is a historical movement which is not complete. Indeed, it is probably only in its earliest stage, and what now strikes many observers as its most important features may prove to be merely passing phases of a great world-historic development.

The first difficulty that meets us lies in the question whether socialism is an ancient or purely modern phenomenon. If socialism be essentially a form of communism, as is sometimes maintained both by friends and opponents of the movement, then it is simply a revival of one of the oldest phenomena in history, the only novelties in it being the modern facts by which it is alleged to be justified or to which revolutionists seek to adapt it. If so, the problem would be greatly simplified, for the arguments against the practicability of communism, grounded in human nature and repeatedly brought out in history, are so strong that the identification of the socialistic movement with it would be sufficient almost to remove it from the region of serious discussion. Again, if we regard socialism as a social and economic system by which the individual is unduly subordinated to society, we must still pronounce it to be an old phenomenon, because in many primitive societies and in many ancient states, both of Greece and Italy, the subordination of the individual to the community in which he lived was excessive. Or again, if we define socialism as a systematic discontent and revolt against prevailing economic conditions, the wide range of the phenomenon at the present day may give it a unique place in history; but it cannot reasonably be considered a new thing, as social discontent was often strong even in old societies, and in a more or less conscious form may be said to have existed in every community from the beginning. The great historic instances of such discontent are found at the declining period of the Greek and Roman republics and during the economic changes which attended the fall of feudalism and of the Catholic Church in so many countries of Europe. The same periods were marked by far-reaching schemes of reform, and by books like the *Republic* of Plato and the *Utopia* of Sir Thomas More, which embodied the ideals of eminent thinkers. Thus we see that dissatisfaction with the present state of things and the longing for the ideal are very old phenomena in the history of the world. The same features are observable in the Hebrew prophets who wrote during the declining period of Jewish history. Lastly, should we grant that socialism is simply a modern phase of the revolutionary spirit, we should still require to know the grounds and motives of it, as a revolution is only the form assumed by the activity of a new force which is powerful enough so to express itself. The violent change called a revolution is one of the oldest things in history; and it really throws little light on a movement when we describe it as revolutionary.

The claim of socialism to be distinctly a new movement may be regarded as resting on two great facts—the industrial revolution and the development of the modern democracy. As England led the way in the industrial revolution, the course of it can be best followed by reference to the history of that country. On the downfall of feudalism towards the close of the 15th century the retainers of the barons were dispersed. Whereas it had been the interest of the feudal noble to support the largest possible number of fighting men, the prestige of the new court aristocracy depended mainly on the rents they could raise. Thus the commercial spirit became a prominent feature of landowning; the small holdings were transformed into large sheep-runs, because the latter paid better; and the old tenants were forced from the land, either to sink into hopeless vagrancy or to drift into the towns. All those tendencies were greatly aggravated through the confiscation of the church-lands on the downfall of the Roman Church and the suppression of monasteries. In this way began the divorce of the worker from the land, which is at once the material of labour and the source of subsistence and of culture. At the same time great changes of enormous magnitude were proceeding abroad. The discovery of America and of the sea-route to India opened up vast countries to European enterprise and colonisation, resulting in the establishment of a world-market, which again gave fresh impetus to the economic change at home. The demand for goods created by the world-market particularly stimulated invention, till during the course of the 18th century a series of new mechanical appliances brought the industrial revolution into full activity. This revolution is still going forward. It is spreading over all countries of the world; and the new motive-power electricity is already beginning to supersede steam. The results of the industrial revolution in so far as they have a bearing on the present subject may be thus summed up. Production is no longer carried on by individual or family labour for local or family use. The labourer has no control of the instruments of labour. Instead of working on his own account with his own small capital, he toils in large factories and other undertakings under employers who own and control the capital embarked in them. Industry is carried on by the united efforts of thousands of men, and is therefore no longer an individual function, but a social and collective one. On these grounds socialists maintain that the energetic individualism which originated and established the industrial revolution has been superseded by the results of that revolution. Individual industry is no longer the normal or prevalent form of industry.

It has been shown (see DEMOCRACY) that the modern democracy is the solid, enduring, and inevitable result of far-reaching causes. The most famous historic expression of it was the French Revolution; and though the ideals of that revolution, liberty, equality, and fraternity, were sadly discredited by the extravagant and sanguinary proceedings in France, it will generally be admitted that a great moral and political gain to the world has been achieved through the growth of democracy. At least no one will deny that its influence has been vast, and as yet is far from exhausted. One of the first effects of the democratic movement was to bring the middle-class into prominence. More recently the working-class has received the chief share of attention. While the middle-class in most civilised countries do more than any other in controlling industry and politics, the working-class is everywhere struggling into action.

The general result of the industrial revolution, therefore, has been the growing concentration of industry and of the capital with which it is carried on; and the development of democracy has tended to inspire working-men with a desire for a larger share of political power and for a fairer distribution of the means of culture and happiness. The rise of socialism as a modern phenomenon was conditioned by the two revolutions. It was the industrial revolution, which had made the working people the victims of machinery and the factory, that Robert Owen had chiefly in view; the great aim of his socialism was to render mechanical invention subservient to human well-being. Saint-Simon (q.v.) was a Frenchman who had lived through the troubles and excesses of the Revolution; and his theories were moulded by that great event. After the destructive liberalism of the Revolution he believed that the time had come for a positive reconstruction of society. His views were more thoroughly elaborated by his disciples. In history they recognised two kinds of epochs, the negative or destructive, and the organic or constructive. The former was marked by the spirit of criticism, anarchy, and war; during the latter religion, love, and the spirit of association were dominant. But the spirit of association will more and more prevail till it embrace the entire world. The keynote of the history of the world during the past has been the exploitation of man by man in its three stages, slavery, serfdom, and wage-labour. The keynote of the future will be the 'exploitation of the globe by man associated to man.' But according to the Saint-Simon school a better society is possible only through the abolition of the hereditary principle, by which ruling classes are from generation to generation secured in the possession of the good things of the world, while the other classes are handed over to perpetual misery. There is only one way to break the fatal chain of continuity, and that is to vest the instruments of production in the state, which will administer them for the benefit of all its members. The state would delegate to associations the practical industrial work, and each man would be rewarded according to his services. Saint-Simon and his school would therefore answer the problems raised at the Revolution not by the restoration of the old feudal and priestly régime, not by following out the negations of liberalism, but by a new positive order, in which the spiritual direction would be given to the men of science and the practical control of production to chiefs of industry. His system was not reactionary; nor was it democratic or revolutionary.

The system of Fourier (q.v.) is in several respects an entire contrast to that of Saint-Simon. Whereas Saint-Simon insisted on the principle of authority, Fourier carried to its extreme development that liberty which had been the chief watchword of the French Revolution. While the school of Saint-Simon gave the state the ownership and control of the instruments of production, Fourier left the capital in private possession, thus securing a fresh guarantee for freedom, but providing against the abuses of private capital by placing it under social control. And Fourier devised another guarantee for freedom by making the commune, or local association, which he called the *phalange*, the cardinal and decisive factor in social reconstruction. In the Saint-Simon school the state is the point of departure and the controlling power, to which the associated bodies are subordinate. With Fourier the commune is substantive, self-sufficing, and independent. The federal organisation into which his communes may enter is entirely voluntary. In short, Saint-Simon's is a centralised socialism, Fourier's is a communal socialism. In this respect Owen agrees with Fourier.

The three systems of Saint-Simon, Fourier, and Robert Owen had been produced during the reaction which set in after Waterloo. Though they had been elaborated in full consciousness of the great events which had marked the closing period of the 18th century, they were intended rather as a corrective of the democratic movement than as a continuation of it. They had little faith in the ordinary democratic ideals. In one important respect, however, they fully participated in the illusions of the early period of the French Revolution. They shared in the comfortable and confident optimism which believed it to be a simple thing to reconstruct society. They thought that they had found a short and easy way to regenerate society. They knew little or nothing of the principles which determine social development, and this perhaps more than anything else lends an air of utopianism and unreality to all their speculations. Their theories never really took root in the practical life of the time.

The French socialism of 1848 had a solid basis in the real life of the time, inasmuch as it entirely and enthusiastically accepted the democratic principles. The first condition of the socialistic proposals of Louis Blanc (q.v.) was the thoroughly democratic organisation of the state; the first duty of such a state was to place its resources at the service of the poor. The state, he maintained, was the banker of the poor. In the social workshops, which he advocated, membership was to be voluntary, and they were to be self-governing, as became the institutions of a democratic state. It has now been fully proved that Louis Blanc's schemes never had a fair trial under the republican governments of 1848. The *national workshops* were only a travesty of his *social workshops*, expressly intended to discredit them. Louis Blanc had not robustness of character or enduring political influence enough to enforce attention to his plans.

While Louis Blanc may thus be regarded as the first historic advocate of the social-democracy, another man who was prominent during the troubles of 1848 must be considered as the founder of a form of socialism still more revolutionary. Proudhon (q.v.) first associated socialism with *anarchism*, which holds that the goal of society is freedom without government. Proudhon was one of the storm-birds of the revolutionary period of 1848; but, with all the violence and extravagance of his utterances in the press and in the chambers, he was too shrewd and kindly a man to have any concern in the rising of June of that year. That was an outbreak of the proletariat, for which the socialist leaders were not responsible.

After the revolution of 1848 France ceased to be the pioneer in socialistic speculation and agitation. Germany and Russia have since produced the foremost men in both departments of activity. The German thinkers, Rodbertus, Lassalle, and Karl Marx, undoubtedly take the first place in the history of socialism as the scientific exponents of the subject, and controversy still thickens chiefly around these three names. To them, and above all to Karl Marx, we are indebted for the prevailing forms of contemporary socialism. While the French socialism that preceded them may be regarded for the most part as ingenious speculation very inadequately grounded in facts, Rodbertus, Lassalle, and Marx seek to justify their theories by a vast and elaborate learning, especially historical learning. They were men of philosophic training, and had a knowledge of economic literature and of the historic economic forces which has seldom been equalled.

The earliest writings both of Rodbertus and Marx were prior to 1848. The manifesto of the Communist party, perhaps the most violent revolutionary document of the 19th century, was drawn up by Marx and Fr. Engels in 1847–48. But their work did not really become historic till a later period. Lassalle, the youngest of the three, was the first to run a very remarkable career as the founder of the social-democracy of Germany. His proposals for the founding of productive associations were substantially the same as those of Louis Blanc, and were even to some degree enforced by the same arguments. The two agitators also resembled each other in the fiery and persuasive eloquence with which they captivated the workingmen of their respective countries. But Lassalle as far surpassed Louis Blanc in philosophic and historical erudition as he was inferior to him in simple integrity and straightforwardness.

While Lassalle therefore was greatly indebted to Louis Blanc for his practical schemes, he derived his theoretical principles to a large degree from Rodbertus and Karl Marx. It would be unjust, however, to regard him as an ordinary borrower. All his activity both as thinker and agitator bore the stamp of his own temperament, which was one of remarkable originality; and indeed the main burden of his teaching is not traceable to any theorist, but had already become the common possession of all socialists who were tolerably well versed in the literature of their subject. The same remark applies to the controversy, whether to Rodbertus or Marx belongs the priority of having established what are considered the fundamental principles of scientific socialism. These principles have already been briefly sketched in the articles LASSALLE and MARX, and need not be repeated here; but we may point out that, while Lassalle dwells chiefly on the small share of the result of production which goes to the labourer as a subsistence wage, Marx finds the keynote of the evolution of capitalism in the large share which falls to the capitalist under the name of surplus value. Both start from the open contradiction in the Ricardian economics, according to which labour is the source of value, but of this value the labourer only gets enough for subsistence according to the usual standard of living, surrendering the remainder to the possessors of land and capital. These deductions from Ricardo formed also the basis of the system of Rodbertus. In other respects, however, he differed greatly from Lassalle, and particularly from Marx. Rodbertus was a Prussian lawyer and landholder, and from temperament and social standing was entirely opposed to agitation and revolution. His general position was social, monarchical, and national. He accepted the monarchic institution in his own country and hoped that the German emperor might undertake the rôle of a social emperor. The socialism which he advocated was a thorough-going national socialism, but he did not expect its full realisation, except as the goal of five centuries of moral and political effort. He proposed that the two classes of landholders and capitalists should continue to enjoy their present share of the national income, but that the results of an increasing production should go entirely to the workers. The state would establish a normal working day, a normal day's work, and a normal wage, which would be periodically revised, and increased according to the increase of production. In this way the practicability and superiority of a national socialism would be shown, the characteristic note of which would be that all income should be dependent on *service*, as contrasted with the ancient income derived from property in slaves, and the incomes of the existing era, drawn from private property in land and capital.

The International was the outcome chiefly of the activity of Karl Marx. The social-democratic movement in Germany originated with Lassalle. At his death in 1864 his union counted only 4610 members, and its history was for some time chequered by petty jealousies and mean intrigues. It succeeded better under the leadership of Schweitzer (1867–71). In the meantime, Bebel, a Saxon workman, and Liebknecht, a disciple of Marx, who naturally were opposed to the Prussian national socialism favoured for purposes of propaganda by Lassalle, had led a strong combination of workmen's societies over to the International. The two parties quarrelled violently for some years, till in 1875 their common interests, and especially the severe treatment of both by the Prussian police, drew them into a union, which was settled at Gotha (1875). They called themselves the Socialistic Working-men's Party of Germany, and drew up a programme, which is still the creed of the German social-democrats. The progress of German social-democracy both before and since the union at Gotha has been marvellous. Five members were elected to the North German Reichstag of 1867. At the elections to the first German Reichstag in 1871 they only polled 120,000 votes; but the number had increased to 339,000 in 1874, and to nearly half a million in 1877. The rapid growth of the party, and the excitement occasioned by two attempts on the emperor's life, led to the passing of exceptional laws against socialists in 1878; but in spite of such legislation their voting strength continued to increase, till in 1887 they counted 763,000 votes, and in 1890 1,427,000, or about 20 per cent. of the total poll. It was also a notable feature of the election of 1890 that, whereas in rural and Catholic districts the socialistic propaganda had hitherto shown little or no symptoms of success, it had at that date made very material progress. The discontinuance of the severe anti-socialist laws, and the more sympathetic attitude of the young emperor on social questions, have also made an important change in the tactics of the party. While their methods and their language, in the press and on the platform, had previously been bitter, violent, and aggressive, there is now a marked tendency to moderation among their leaders. They see the hopelessness of overt opposition to the government, and they are content to await the development of the economic forces, which, following their teacher Marx, they believe will inevitably establish socialism in the fullness of time. But this change of tactics has not received the unanimous approval of German socialists, and a small party has already seceded from the main body.

Next to the Marx socialism the most prominent form of socialism is anarchism. As we have seen, the originator of anarchism was Proudhon; and its most notable expounder was the Russian Bakunin (q.v.). The characteristic feature of anarchism is really a political theory, the denial of government, and may be held with or without the economic principles which constitute the essence of socialism. The anarchic socialism of Bakunin was atheistic, materialistic, and revolutionary. He condemned all forms of government, whether based on the will of a single ruler or on universal suffrage, as necessarily leading to tyranny. The one great aim of every reasonable creature is scientifically to know the laws of nature and to put himself in harmony with them. Thus the goal of social progress is an enlightened freedom, in which external control is superfluous and despotic, and every man is a law to himself. For attaining this end Bakunin advocated a policy of unsparing destruction of the existing society. The future organisation would proceed from the free initiative of the people, who will group themselves in associations, all the arrangements of which, including the institution of marriage, will depend on the free consent of the members. And these free associations will group themselves into a federation, formed and maintained on the same principle of freedom. In economics the school of Bakunin advocate a collectivism which is essentially the same as that of Marx. The International (q.v.), however, was broken up through the differences between the Marx party and that of Bakunin. The theories of anarchism have had a very considerable influence in France, Spain, Italy, and Russia. The risings in southern Spain in 1873 were stimulated by anarchist teaching. In 1883 the great trial of anarchists at Lyons made an interesting revelation of the theories and methods recognised by that school of socialists. It is not clear how far the revolutionary party in Russia has been affected by anarchist doctrines. Kropotkine, the eminent Russian exile, and the distinguished French geographer Reclus may be regarded as the chief living exponents of anarchism. The Russian revolutionary party has no doubt been greatly influenced by men like Bakunin and Kropotkine, but it has also owed much to Lassalle, Marx, J. S. Mill, Herbert Spencer, and other thinkers who have no sympathy with anarchism as a special form of political and economic thought.

During the last generation socialism has undoubtedly made great progress throughout the civilised world. Yet, except in Germany, and perhaps Denmark, the number of the avowed and active adherents of the movement is still comparatively small. The growth of the socialist voting power in Germany has been already noted. In Denmark the numbers of the socialist party are numerous enough to organise great demonstrations and to support a daily newspaper with a large circulation. French socialism is influential only in Paris and the industrial centres, and has returned a few representatives to the Chambers. In Italy and Spain there is a considerable socialist feeling, but it is mostly latent, and therefore cannot easily be measured. The movement is spreading in Austria and Belgium; whilst as regards Holland, Sweden, and Norway we can only say that the party, though increasing, fills as yet but a small portion of the national life. The revolutionary party in Russia has been exceptionally active, but its numbers have been small. In England, after having died out almost for a generation, the movement took a fresh start about 1883. For some years after that date it attracted great attention, and gained a number of able and active adherents; but it has again entered upon a quiescent stage. Socialism has also spread to America and the Australian colonies; yet, while the labour movement has most powerfully affected both continents, it cannot be said that organised and avowed socialism has made very marked progress.

The general result is that outside of Germany and Denmark the number of avowed and active socialists is comparatively small. On the other hand, few will doubt that the direct and indirect influence of socialism on social economic and political thought has been very great.

Looking to the main drift of speculation on this subject both in the past and present, we may briefly define the fundamental principles of socialism as follows. Socialism holds that the present system of industry, which is carried on by private competing capitalists, served by competitive wage-labour, must be superseded by a system of free associated workers utilising a collective capital with a view to an equitable system of distribution. On this theory private capital will be abolished, and rent and interest will cease. The method of distributing the fruits of labour advocated by many socialists cannot be distinguished from communism. But this is not an implicate of the historic socialism. Several methods of remuneration professing to be equitable have been put forward, and each member of an association of workers would be free to use his special income as he pleased. In fact, all such moderate wealth as would be devoted, not to production, but to consumption, might be regarded as at the free disposition of the owner. And a method of distribution which fixed the remuneration of each in proportion to his services might admit of a very considerable variety in the amount of incomes. But the individual ownership of capital and the free disposal of it and the individual appropriation and possession of the advantages derivable from private capital in the form of rent and interest would terminate. A conspicuous exception to such an arrangement is found in Fourier, who made the continuance of private capital a substantial feature of his system. It remains, however, that the historic socialism in general as well as the active and organised contemporary forms of socialism demand the absorption of private in an absolutely collective capital. In the definition above given socialists of the Marx and of the anarchist schools would agree.

Probability is the guide of life, and it is extremely improbable that any system of industry involving the abolition of private capital should ever become prevalent. And if it were practicable it would greatly limit the legitimate and reasonable interests of human freedom. The materialism of the Marx and anarchist schools is also a grave objection to their theories as historically presented to us. Both schools too have laid most excessive stress on the virtues and possibilities of the revolutionary method of action. The evils of the existing society are not due merely to bad social-economic and political mechanism; they are rooted in human nature itself. No revolution can produce a magical change in human nature. A revolution can indeed remove abuses; but they always return in a modified form, or the old abuses are replaced by new ones. Human society and human nature can be radically improved only by a long and gradual organic change, economic, political, and ethical. It is particularly utopian of the Marx school to believe that the struggle of classes can be terminated by a great revolutionary act. In short, the socialism of Marx is altogether too absolute, abstract, and remote from the facts of history and existing human nature. His theory of surplus value is the most striking example of this abstractness; instead of being the key to the development of capitalism, it is really the vitiating element in a great and elaborate historical production.

Must we then regard socialism as a passing and errant phase in human development, which, after exciting wide-spread attention, like the forms of communism that have emerged at certain periods, is, like them, doomed to disappear? The answer to this question can really be given only in the history of the future. For socialism is not an abstract and completed system identifiable with the theories of Marx or Bakunin; it is a thing in movement and subject to incessant change. But so far as the movement has proceeded we may justly say that it has had the following permanent results: (1) It has greatly helped to give prevalence to the historical conception of political economy. The idea of change has been natural to socialists; their subject has led them to study the rise, growth, decline, and fall of economic institutions. The great principle of evolution, as taught by Hegel and Darwin (see below), has been a commonplace in socialistic speculation. (2) Socialism has greatly deepened and widened the ethical conception of political economy. It has in season and out of season taught that the entire technical and economic mechanism should be made subordinate to human well-being, and that moral interests should be supreme over the whole field of industrial and commercial activity. The charge sometimes brought against socialism that it appeals only to the lower instincts of man is very wide of the mark. It would be a juster criticism to say that it inculcates an altruism unattainable by any probable development of human nature. (3) Socialism has brought the cause of the poor most powerfully before the civilised world. As the cause of the poor represents the social and economic side of the vast and inevitable movement of modern democracy, it is not likely again to pass out of the attention of the world, but will be the burning question in every civilised country for a long time to come. (4) Socialism has given an exhaustive criticism of the existing society and of the prevalent economic theories. In many things the criticism has been exaggerated, but it has been also in many things most valuable. Almost every economic treatise now appearing bears the marks of socialistic criticism of the present society.

Under all the above heads socialism has made a deep and abiding impression on the thought and activity of the world. Here, again, Germany leads the way in the recognition of the influence of socialistic theories, and this is particularly observable in the *Socialism of the Chair* and in the *State Socialism* which have played so great a rôle in recent German discussion and legislation. The socialists of the chair are an influential group of professorial and other economists, whose position may be best described as illustrating the influence of the socialist movement in the above directions. They recognise the historical and ethical character of economics; labour in all its aspects—in other words, the cause of the poor—is the subject of the most serious and exhaustive investigation; and all of them make important concessions to the socialistic criticism of the existing society. Bismarck was the redoubtable antagonist of the social democracy, regarding it as subversive of church and monarchy and fatherland; but he had considerable respect for socialistic principles, and he was prepared to hold the state as so far responsible for its suffering members. The state socialism of Bismarck was an outcome of this sense of responsibility, and the same feeling has been emphatically expressed by the Emperor William II.

The above considerations point to large and important changes in the existing society; yet they are perfectly consistent with the continuance of the present system of industry, the characteristic feature of which is, as we have seen, that it is carried on by private capitalists served by wage-labour. In spite of all such changes the worker would remain divorced from land and capital; he would have no control of the sources of subsistence and culture; and he might still have to be content with little better than a subsistence wage. Socialism, however, desires not a modification, but a renovation of the existing industry, and through it of the existing society. While, therefore, we may admit that it has exercised a very considerable influence on social-economic thought and practice, the probability is that it will fail in making the revolution in society which it proposes to accomplish.

But it may also be maintained that, though the historic and contemporary socialism has been so much disfigured by extravagance, and has taken too little account of the fundamental principles of human nature, the main aim of the movement may be perfectly sound. The extravagances of socialism are obvious and confute themselves. Like other systems making great claims on mankind, it must be tried by its fundamental principles, which should be distinguished from the accidentals that have been associated with it in history. It may be said that we have only to liberate the historic socialism from its too abstract, absolute, and ultra-revolutionary forms and we have a new type of industrial organisation which has a reasonable claim to supremacy in the future. We can conceive industry as under the entire and efficient control of associated workers, making an equitable distribution of the produce, while private capital could be maintained in so far as it is necessary to freedom and individual development. In like manner the hereditary principle with all the implicates so important to society would be preserved, and by social control protected from existing abuses. As the co-operative workers would have effective control of the instruments of labour, that divorce of the labourer from the means of subsistence and culture which was one of the most lamentable results of the industrial revolution would terminate. The present differences between capital and labour would cease, inasmuch as labour would be united with capital under one and the same social management. The hours of labour and the remuneration of labour would be mainly and normally regulated not by competition, but by reference to reasonable human needs. For the realisation of such a condition of things much would depend on the growth of habits of free self-government and self-control. It could be brought about, not by a political catastrophe, but by a long and gradual process of organic change, especially in the minds and morals of the masses of the industrial population.

In short, socialism is the extension to industry and economics of the free self-governing principle recognised in democracy. It is industry of the people, by the people, for the people. When we remember that this type of organisation has from the time of Simon de Montfort taken more than six centuries to attain to imperfect realisation in the English parliament, it will be clear that it cannot succeed in the industrial sphere in a day. It may be maintained, however, that we can see the substantial beginnings of such an economic change in the extension of social control through (1) the state and (2) the municipality or commune, and (3) in the growth of the co-operative system. The company is at present the growing power in industry; but even as regards the great companies (4) the control of the state and of social opinion is continually extending. In the application of the profit-sharing principle we may discern a possible change towards a system in which the workers may have an interest in and control of the large industry. And in the continual development and concentration of business of all kinds in these great industries we may see the mechanism by which they might be brought under social management. The great companies are no longer conducted by the owners of the capital as such, but by a paid staff of officials under a manager; and the whole organisation could without shock be transferred to the direct service of the community.

It will be clear that socialism is a question for the future. Only the future can disclose how far and how soon any system of free associated workers can supersede the prevalent system of competitive industry served by wage-labour. And, as we indicated at the outset, the drift of opinion about socialism will largely depend simply on the meaning which prevalent use and wont give to the word.

Relation of Socialism to Darwinism.—Many students of socialism find a difficulty in understanding its relation to the Darwinian theory, according to which development depends on the struggle for existence, resulting in the survival of the fittest. Reasonable socialists must admit that such a struggle is a prime fact in the history of human society, and that it is a cardinal principle of human progress that the competitive system is only a modern form of the struggle for existence, and is therefore a necessary stage in the progress of mankind. On the other hand, it is enough to point out that the struggle for existence is only one side of human evolution. Another side not less important is seen in the development of the principle of association or community, in the continual effort to moralise the struggle, to place it under the regulation of rational, ethical, and artistic ends and ideals. In short, the moral and social progress of the world has largely consisted in mitigating, limiting, and regulating the struggle for existence. The struggle for existence, however, is not thereby abolished. It is only carried forward to a higher plane. The development of the social principle or principle of association is itself a potent element in the struggle; for the struggle is not one between individuals merely; it is waged also between communities, which on the whole are continually progressing, and an improvement in social organisation may be decisive of the result. In the great struggle for existence which is always proceeding between the nations of Europe a large advance, for example, in the education and social condition of the people of one nation may more than any other factor turn the scales in its favour. The family virtues—good faith, justice, and humanity—have always been powerful elements in the development of society. They are all phases of the moral and social progress of the world. Socialism claims to have brought forward a type of industrial organisation which can best continue and promote the ethical and social progress of mankind. The competitive system is the latest form of the struggle for existence, and socialism is the latest theory for its regulation.

Social War. See ROME, Vol. VIII. p. 790.

Societies are associations of individuals for the promotion or accomplishment of some particular object, such as the promotion and investigation of almost every well recognised branch of science, art, and literature; the diffusion of knowledge, religion, and morality; intercourse between those of the same profession or trade; the removal of legal grievances; mutual aid in case of distress; and an abundance of other aims, which are either beneficial to the general public or to the members of the society alone. The great scientific, literary, and art associations are many of them separately treated in this work (see ROYAL SOCIETY, ROYAL ACADEMY, &c.). So are many special institutions like the Humane Society (q.v.), the S.P.C.K. (see CHRISTIAN KNOWLEDGE). Others are dealt with in the articles on the subjects with which they concern themselves (LIFEBOAT, TEMPERANCE, BROWNING, &c.). In Britain the term academy is usually reserved for art associations; but on the Continent the great national literary and scientific organisations are usually styled academies, and are treated at the article ACADEMY. So with many American learned associations. See also MISSIONS, BOOK-CLUBS, SECRET SOCIETIES.

The following is a list of the best-known British societies, associations, and institutions in order of date, fuller information as to which may be sought in the *Year-book of the Scientific and Learned Societies of Great Britain and Ireland* (published annually since 1884). It should be noted that in some cases the society arose out of a minor and older organisation; was itself founded under a somewhat different name; or received its charter of incorporation years after its foundation.

Royal Society (London)	1660
Royal Dublin Society	1684
Christian Knowledge	1698
Society of Antiquaries	1707
Society of Dilettanti	1734
Society of Arts	1753
Manchester Lit and Phil.	1781
Royal Soc. of Edinburgh	1783
Highland and Agricultural	1784
Royal Irish Academy	1786
Soc. of Antiquaries of Scot.	1780
Linnean	1788
Royal Institution	1799

Of American learned associations, whether calling themselves Academy (q.v.) or not, the following are among the more important of several thousand.

American Philosophical Society	1743
American Academy of Arts and Sciences, Boston	1780
Connecticut Academy of Arts and Sciences	1799
New York Historical Society	1804
Academy of Natural Sciences, Philadelphia	1812
New York Academy of Sciences	1818
Boston Society of Natural History	1830
Smithsonian Institution	1846
American Association for the Advancement of Science	1847
American Geographical Society	1852
National Academy	1863
Social Science Association	1865
Numismatic and Archæological Society	1866
American Folklore Society	1888

Society Islands. See TAHITI.

Socinus, the name of two celebrated heresiarchs, uncle and nephew, who have given name to a sect of Christians, the Socinians, whose doctrines, though by no means identical, are to a large extent those of the modern Unitarians.—Lælius Socinus, or Lelio Sozzini, was born in 1525 at Sienna in Tuscany, of a family long distinguished for its cultivation of literature and science. His father, Marianus Socinus, was an able lawyer, and designed his son for the same profession. But Lælius soon displayed a strong preference for theological inquiry, and in order to better prosecute his biblical studies he made himself familiar with Greek, Hebrew, and Arabic. The only result of his legal training that one can discern is an obstinate aversion to believe anything 'unreasonable.' The principles of the Reformation had slowly found their way into Italy, and in 1546 a secret society of forty distinguished men was formed at Vicenza for the discussion of religious questions. The conclusions at which they arrived were unfavourable to the dogma of the Trinity, which they held to have been borrowed by the early church from the speculations of Greek philosophers. The purpose of their meetings together having been discovered, the society broke up. Some of the members were arrested and put to death, others sought safety in flight. Among the latter was Socinus, who travelled in France, England, Holland, Germany, and Poland, making the acquaintance, and acquiring the esteem, of many transalpine scholars, and finally settled in Zurich, where he died in 1562, when only thirty-seven years of age. Lælius Socinus, unlike most heretics, was a modest and reticent man. He united in altogether unexampled degree the warmest piety with complete freedom in theological speculation.—See Illgen's *Vita Lælii Socini* (Leip. 1814), and *Symbolæ ad Vitam et Doctrinam Lælii Socini* (Leip. 1826).

Faustus Socinus, or Fausto Sozzini, nephew of the preceding, was born at Sienna, 5th December 1539. He lost his parents while still young, hence his education was neglected; but this rather helped than hindered him to become a heretic before he was out of his teens. At twenty-two he repaired to Lyons, where he was when he got news of his uncle's death. He immediately proceeded to Zurich to take charge of his papers, next entered the service of the Grand duke of Tuscany's sister, and during twelve years seemed to forget, amid the cares of office and the dissipations of society, the thorny questions of theology. In 1575 he retired to Basel, to prosecute his studies more closely, and in November 1578 he set out for Klausenburg, at the request of George Blandrata, whence next year he went to Poland. Anti-Trinitarianism was even stronger here than in Transylvania, and Socinus soon obtained great influence. He preached and disputed and wrote with a zeal that his successors never displayed. His position in relation to the Reformers was that Luther and Calvin had rendered great services to the cause of religion, but that they had not gone far enough, that the only solid basis on which Protestantism could rest was human reason, that everything that contradicted it should be rejected as false and incredible, and that dogmas that were absurd should not be allowed to shelter themselves from criticism because their defenders chose to call them mysteries. The Protestants were alarmed, and the ablest among them undertook publicly to confute Socinus. A disputation was held in the college of Posna, which ended in Socinus reducing all his opponents to silence; but they retaliated after the unscrupulous fashion of the times by trumping up against their vanquisher a charge of sedition, which, although ridiculously groundless, made it necessary for Socinus to withdraw from Cracow. While living in retirement on the estate of a Polish noble, Christopher Morsztyn, he married the daughter of his protector. She seems to have been a tender and affectionate wife; and when Socinus lost her in 1587 he almost broke his heart through grief. About this period his property in Italy was confiscated; but he had powerful and wealthy friends in Poland, who proved generous to him in his needs. In 1588 he took part in the synod of Brest (on the borders of Lithuania), and combated all the principal dogmas of the church—the divinity of Christ, propitiatory sacrifice, original sin, human depravity, the doctrine of necessity, and justification by faith. In 1598, on the publication of his *De Jesu Christo Servatore*, his enemies stirred up the populace of Cracow against him; and Socinus was torn from a sick-bed and nearly murdered. Soon after he left the city and found a refuge with one of his friends in the village of Luclawice, where he died, 3d March 1604. The works are no longer read; but his opinions have never wanted advocates in any Protestant country. He and his uncle may be regarded as precursors of that spirit of Rationalism which has rooted itself so deeply in the thought of the modern world.

See Przypkowski's Life, prefixed to a collection of the works of Socinus in the *Bib. Frat. Polonorum* (Amst. 1636; Eng. trans. 1653); Bayle's article in the *Dictionnaire*; Toulmin's *Memoirs* (Lond. 1777); a Life by Wallace (1850). See also Fock, *Der Socinianismus* (1847), and the article Unitarianism.

Sociology, a hybrid word brought into currency by Comte with the meaning of 'social politics,' deals with man as a social being (Aristotle's *zōon politikon*), and so has for its subject the origin, organisation, and development of human society and human culture, especially on the side of social and political institutions. The field of Anthropology (q.v.) is usually restricted to the discussion of the earlier stages of social development and survivals from that stage into the present. Speculation on the subjects included in the wide field of sociology is as old as literature; and the names of Plato, Aristotle, Hobbes, Vico, Herder occur as prominent amongst those who have dealt with its problems. But it was Comte who may be said to have made the first serious attempt to make sociology a science, and a sketch of his views will be found at Positivism. The methods of modern sociology are, however, especially identified with the work of Herbert Spencer, who makes the science a series of generalisations on the correspondences and contrasts between individual organisms and communities or societies as social organisms, with their structures and functions, their periods of growth and decay. The forms of government—civil, ecclesiastical, military, industrial, ceremonial—are the structures of communities; sentiments, ideas, industrial processes, fine arts may be regarded as functions. See the article Spencer; Spencer's *Principles of Sociology*; the articles Anthropology, Evolution, Family, Feudalism, Government, Marriage, Political Economy, Politics, Poor-laws, Prisons, Socialism, Woman's Rights, and the works cited under these heads.

The name of Social Science has in Britain been specially given to the study of all that relates to the social improvement of the community. A society, called 'The National Association for the Promotion of Social Science,' was organised at a meeting held under Lord Brougham's auspices in July 1857, to consider the best means of uniting together all those interested in social improvement; and till 1884 held annual congresses in large towns throughout the United Kingdom. At the last congress the Association comprised five sections—(1) Jurisprudence and Amendment of the Law (sub-section, Repression of Crime); (2) Education; (3) Health; (4) Economy and Trade; (5) Art.

Socotra, an island in the Indian Ocean, 150 miles E. by N. from Cape Guardafui, and 220 from the southern coast of Arabia. Seventy miles long by twenty broad, it has an area of 1380 sq. m. The interior embraces numerous barren plateaus (1500 to 2000 feet), with several well-wooded mountains, rising to 4500 feet; there are fertile valleys between the ranges and belts of rich soil along the coasts. The climate is moist and warm, but healthy. Aloes and dragon's blood are the chief commercial products. The inhabitants, about 10,000 in all, live on dates and the produce of their sheep, goats, and cows. They belong to two distinct types—one with a comparatively light-coloured skin and straight hair, the other darker with curly hair. But all alike speak the same peculiar language, which has certain affinities with the South Arabian dialect of Mahra. The people show traces of intermixture with Negro, Arab, and Indian tribes; and in ancient times the inhabitants of Socotra were believed to have been acquainted with Greek civilisation and later to have been Nestorian Christians. From the 16th century at least they owed some sort of allegiance to the sultan of Keshin on the Arabian coast. After being occupied by Britain in 1835–39, the island was taken under British protection in 1876 and formally annexed in 1886. The chief town is Tamarida on the north coast. The Royal Society and the British Association sent out in 1880 a commission of scientific men to investigate the botany and zoology of the island; and a German expedition (Drs Riebeck, Schweinfurth, and others) followed them the year after.

See Yule's *Marco Polo* (vol. ii.); Wellsted in *Jour. Roy. Geog. Soc.* (1835); and *Nature* (1880, 1881).

Socrates, the Athenian philosopher, was the son of Sophroniscus, a sculptor, and Phænaretē, a midwife. As he was at least seventy years old at his death, he cannot have been born later than 469 B.C. He is said, though only by late writers, to have followed his father's profession for a time; and, in the days of the traveller Pausanias (about 160 A.D.), a statue of the Graces, standing at the entrance to the Acropolis, was ascribed to him—with what amount of truth it is impossible to say. He received the usual education of an Athenian youth, and learned also geometry and astronomy. He was acquainted with the philosophy of Anaxagoras (q.v.), probably only through reading his books, and with other speculations about the physical universe. But he came to consider such inquiries fruitless and disappointing. 'To know one's self' was a more pressing task than to know about nature. The most important influence on his mental development was his intercourse with the various Sophists (q.v.) who frequented Athens. Plato (*Meno* 96 D) makes him speak as if he had been a pupil of Prodicus; but he was in no sense a disciple of that sophist. Though in Xenophon's *Memorabilia* (ii. 1) he reproduces Prodicus' moral tale of 'The Choice of Hercules' with approval, he apologises, with obvious irony, for not adorning it with the fine language employed by the sophist, who, we know from Plato's *Protagoras*, was fond of pedantic verbal distinctions. With the other famous sophists of the time (Protagoras, Gorgias, Hippias, &c.) Socrates stood only in the relation of a controversial disputant, though it is clear from the caricature of him by Aristophanes in the *Clouds* (423 B.C.) that ordinary Athenian opinion regarded Socrates as a typical sophist. It may be noted also that Aristophanes, following the vulgar conception of a philosopher, represents his sophist Socrates as engaged in physical researches, though many of the sophists, like Socrates himself, occupied themselves not with nature but with questions of direct practical human interest. Socrates, in bringing down philosophy from heaven to the common life of men (as Cicero puts it), was only carrying out in a conspicuous and earnest way one of the new intellectual tendencies of his age. Socrates, we might say, was the greatest of the sophists, and therefore more than a sophist. Euripides, the poet of the new ideas, is said to have been intimate with Socrates; and the comic poets alleged that Socrates helped him with his tragedies. Whether Socrates really met Parmenides (q.v.), as represented by Plato, we have no means of saying.

Socrates took part in three campaigns: he served at Potidæa between 432 and 429, at Delium in 424, and at Amphipolis in 422. His bravery, his extraordinary physical vigour and indifference to fatigue, or cold, or heat, became known to his comrades during these campaigns. He was a good citizen, obedient on principle to the laws of his city; and he did not hesitate to face the anger of the people or of tyrants when duty required. The only political office he ever held was when in 406 he was one of the senate of Five Hundred, and then, whilst he was one of the presiding tribe, he alone refused, at great personal risk, to put to the vote the illegal proposal to try in a body (instead of individually) the generals who had deserted the disabled vessels and left the dead unburied at Arginusæ. And, again, during the usurpation of 'The Thirty' he dared to disobey an illegal order. He held aloof from politics, restrained by what he believed to be a divine warning, and considering that he had received a call to the pursuit of philosophy and could serve his country best in that way. Socrates wrote no books. He set up no regular school of philosophy. He simply lived constantly in public, frequenting the gymnasia and the market-place. He did not care to go outside the city walls; 'the trees had nothing to teach him' (as he says in Plato's *Phædrus*). It was from men and about men, men of all sorts and conditions, that he desired to learn, wiser than others only in being conscious of his own ignorance. It was in this sense that he interpreted the Delphic oracle, which had said that no one was wiser than Socrates. Out of his wide circle of acquaintances some came to be attached to him more closely by ties of affection and admiration; yet there was no formal bond of discipleship. We should rather speak of the young friends or the companions than of the disciples of Socrates. From two of these, Xenophon and Plato, we learn all we can know with certainty about his strange personality and his way of thinking. Yet there is this difficulty, that, while Plato often makes Socrates the mouthpiece of ideas that were in all probability not held by him, Xenophon, a soldier and by no means a philosopher, makes Socrates a very much more commonplace person than he must have been. And it must be remembered that Xenophon wrote expressly to justify Socrates to the average Athenian. If we were dependent on Xenophon alone, it would be unintelligible how Socrates could have been the initiator of a great movement in philosophy, and how the Athenians could have been suspicious of so safe and conservative a moralist. Though Plato is apparently not bound by any rigid considerations of historical accuracy in his dialogues, we may yet accept the picture he gives us of the habits and conversation of Socrates as a true portrait—a portrait painted by a great imaginative artist. Aristotle, though of course he could only know about Socrates through Plato and others, sometimes supplies us with a valuable test to discriminate the genuinely Socratic from the purely Platonic elements in the dialogues. Xenophon becomes a useful authority when read in the light of what we know from Plato. Many sayings of Socrates convey profounder meanings to the readers of Plato than they probably did to Xenophon himself. Where Xenophon sees only a prudential maxim, Plato finds the germ of a philosophical principle.

In personal appearance Socrates was odd and even ugly, conspicuously so among a handsome race. He had a flat nose, thick lips, prominent eyes. Alcibiades (in Plato's *Symposium*) compares him to a figure of Silenus. His robust constitution has already been referred to. He always went barefooted, even during a Thracian winter, and wore the same homely clothing all the year round. He was indifferent to luxury and even to ordinary comfort; but he was by no means an ascetic. Habitually abstemious and simple, and possessing perfect control over all his appetites, he could at a banquet drink more than any one else without being overcome. He delighted in the society of youths, especially if they had fair minds in fair bodies. From a modern point of view, he might seem to pay too little regard to the duties of family life. But we must remember that, though above his age in many ways, he was still of it, an Athenian living almost entirely in a society of men. The well-known gossip about his wife Xanthippe comes to us mostly from late sources. Xenophon only tells us that she had a shrewish temper, which Socrates bore patiently, admonishing his eldest son Lamprocles of the duty of gratitude to his mother (*Mem.* ii. 2). It is easy to believe that a man who had a mission, who was willingly poor, and lived very much in public may have been a trying husband, even to an Athenian wife.

There has been much discussion about the 'divine sign' (*daimonion*) of which Socrates used to speak as a supernatural voice which guided him every now and then, according to Xenophon telling him to act or not to act, according to Plato only restraining him from action, never instigating. Later writers, especially in Christian times, speak of it as a dæmon, genius, or attendant spirit. For this there is no authority whatever in Plato and Xenophon. On the other hand, we cannot, with some modern writers, identify it with the voice of conscience. Socrates speaks of it as a peculiarity of his own, and it had not to do with the moral quality of actions in general: it was an occasional inward oracle about the future. Socrates, not disbelieving in oracles and divinations (though very likely laying less stress on them than the pious Xenophon would have us suppose), seems to have had certain vivid presentiments which he took for special divine monitions; and it is possible, as has been suggested, that he was subject to occasional hallucinations of hearing, such as may occur even in quite sane and healthy persons. Socrates was eccentric in some ways, and we know that he occasionally became so absorbed in meditation as to become insensible of the outer world. Alcibiades (Plato, *Symp.* 220) relates that Socrates once stood still for twenty-four hours continuously, entranced in thought. It has also been suggested that in some of his allusions to the divine sign there is a trace of irony, and that he may be indirectly satirising the prevalent belief in divination, claiming to have an oracle of his own.

In any case the average Athenian thought there was something blasphemous in the attitude of Socrates to religion. He was charged in 399, under the restored democracy, (1) with neglecting the gods of the state and introducing new divinities (*daimonia*), and (2) with corrupting the morals of the young. These were very much the same charges which had been made against him as the typical sophist by Aristophanes twenty-four years before. They were now made the subject of a legal prosecution by Melētus, Anytus, and Lyco. The Athenian people, though generally tolerant, were liable to outbursts of fanaticism; and it must be remembered that the religion of a Greek state was an integral part of its social and political institutions. Furthermore, among the companions of Socrates had been several of the leading men in the oligarchical faction, such as Critias, Charmides, &c.; and he had also been associated with Alcibiades, who had done so much injury to Athens. A mixture of democratic indignation with that bigoted religious and moral conservatism which is not incompatible with democracy must account for the prosecution and its issues. Plato's *Apology* probably gives the substance of the actual defence made by Socrates—a bold vindication of his whole life, and not such as would be likely to conciliate an Athenian popular jury. Yet the vote of condemnation was carried only by a very small majority (six out of, probably, 500). The punishment had still to be decided on. Socrates himself declared that, if he were treated as his life deserved, he should be maintained at the public expense in the Prytaneum. But at length, yielding to the pressure of his friends, who were trying to save him, he agreed to pay a fine of thirty minæ (i.e. about £120), for which his friends undertook to be his sureties. Provoked by what doubtless seemed to them obstinacy and insolence in the old man, the judges voted the penalty of 'death,' which Melētus had proposed in the indictment: according to Diogenes Laertius (q.v.), this was carried by eighty more votes than the original condemnation. The execution of the sentence was delayed for thirty days because of a sacred embassy to Delos. His friends, who had free access to him, planned his escape from prison; but he refused to break the laws of the state. His last day was spent with his friends, as described in Plato's *Phædo*; and in the evening he drank the hemlock. 'Such was the end,' Plato makes Phædo say, 'of our friend, whom I may truly call the wisest and justest and best of all the men whom I have ever known.' Later writers tell how the Athenians repented and punished his accusers; but there is no evidence for this in the writers of the 4th century B.C.

The life and philosophy of Socrates are inseparably connected. Yet he must not be thought of as simply a good man who tried to influence others for good. He sought to base conduct on knowledge. He went about convincing men not so much of sin as of ignorance. What is called the 'irony' of Socrates is his manner of affecting ignorance in the presence of the seeming wise, in order to draw from them an admission of the confusions and contradictions resulting from their opinions. But his conclusion was not mere scepticism or despair of knowledge. He claimed to follow, in the intellectual sphere, his mother's profession, and to help those in labour with new ideas to bring them to the birth: this is his 'maieutic,' i.e. obstetric art. For this reason he always adopted the method of question and answer—the 'dialectic' method in its literal sense. Aristotle (*Met.* xiii. 4) says that Socrates introduced the method of *induction* and the search for *general definitions*. This is a somewhat technical and formal description of the manner and aim of the conversations of Socrates. The Socratic 'induction' consists in going to particular instances. Socrates was laughed at for the homeliness of his illustrations: he was always talking about carpenters and weavers and shoemakers.

Ethics was the only part of philosophy with which Socrates cared to occupy himself, and in ethics his main doctrine may be summed up in the formula 'Virtue is knowledge; vice is ignorance.' (Bentham's saying, 'Vice is miscalculation,' is a somewhat mean-looking version of this.) It follows from this fundamental principle that virtue is one, the excellence of each good quality just consisting in the *knowing* what ought or ought not to be done. It follows also that no one can know (in the truest sense) what is right and yet do what is wrong. In Xenophon we do not find Socrates maintaining any of these opinions in quite so explicit and paradoxical a form. In Plato they are carried out to their logical consequences (see PLATO). We find, e.g., that Xenophon makes Socrates say that rulers should be those who *know* the art of ruling. This sounds commonplace enough. But we cannot say that Socrates did not go on to propound Plato's paradox that the perfect state would therefore be one in which the rulers were philosophers.

Xenophon represents Socrates as using the argument from design to prove the existence of the gods. But we cannot say with certainty how far his opinions about the gods differed from those of the popular religion. We may fairly suppose that they approached more nearly to those of Plato than to those of the average Athenian. On the other hand, from the language of Plato's *Apology*, it seems pretty clear that Socrates did not hold the definite views about the immortality of the soul which are maintained in the *Phædo*, but left the question of a future life quite uncertain.

Socrates founded no special school of philosophy, but gave their starting-point to several distinct schools. Euclides of Megara (not to be confounded with the great mathematician of Alexandria who lived a century later) took up the Socratic dialectic as his main object of study, and, combining Socratic with Eleatic influences, became the founder of the Megaric or 'Eristic' (i.e. disputatious) school. On the other hand, Antisthenes (q.v.) the 'Cynic,' who taught that virtue was the sole end of life, and Aristippus (q.v.) of Cyrene, who taught that pleasure was the end, neglected the intellectual and logical aspects of the Socratic teaching and took a narrowly practical view of the object of philosophy, each maintaining an opposite extreme in his view of goodness. These are often called the 'one-sided' or imperfect Socratics. Plato alone inherited his master's spirit in its fullness.

The part of Zeller's *History of Greek Philosophy* dealing with Socrates is published separately in the English translation. The materials for the life and teaching of Socrates are Xenophon's *Memorabilia* and *Symposium* (the *Apology* ascribed to Xenophon is probably spurious), and Plato, *Apology* (most strictly historical of his writings), *Crito*, the narrative parts of the *Phædo*, *Symposium*. For further references, see XENOPHON, PLATO; see also article on 'the dæmon of Socrates,' by H. Jackson, in *Journal of Philology*, vol. v.

Socrates, a church historian, born and brought up at Constantinople about the end of the 4th century A.D. Little is known of his life save that he followed the profession of an advocate. His *Ecclesiastikē Historia* covers the period from 306 to 439, and was most probably written about 440. As history its chief value lies in its transparent honesty, for the writer's grasp of the subject was feeble and his knowledge small. He borrowed from Eusebius, Rufinus, Athanasius, besides eye-witness and oral tradition, mainly from the members of the Novatian party at Constantinople. He had a profound reverence for Origen, and a high regard for Greek culture; and while he himself maintains an easy orthodoxy, he is indifferent to dogmatic definitions and tolerant of erroneous opinion when not noisy. Editions are by Hussey (1853) and W. Bright, with Introduction (1878); there is an English translation in Bohn's Library (1851), another by Professor A. C. Zenos in Schaff's 'Select Library of Nicene and Post-Nicene Fathers' (2d series, vol. ii., New York, 1891).

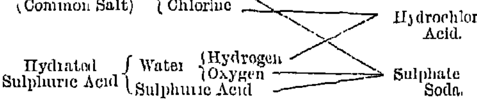
Soda. In its widest sense the manufacture of soda embraces a chain of operations which includes the making of Sulphuric Acid (q.v.), sulphate of soda, Hydrochloric Acid (q.v.), Bleaching Powder (q.v.), caustic soda, soda ash (alkali), and crystals of soda (washing-soda). From some of these processes valuable by-products are also obtained, such as iron, copper, and even silver from the pyrites, after the latter is burned to yield the sulphur required to make the sulphuric acid. This sulphur is now recovered on a very large scale from exhausted black-ash by Chance's process.

Copyright 1892 in U S by J B Lippincott Company

Formerly most of the soda of commerce was extracted along with other products from the ashes of certain seashore plants (see BARILLA, and KELP). Natural carbonates of soda (sodium carbonates) are found in different parts of the world, and in some places are worked for use. See SODIUM. The quantity of soda obtained from all other sources is, however, now quite insignificant in comparison with that produced by the decomposition of common salt (chloride of sodium). This manufacture occupies the chief place among British chemical industries, and is conducted on a gigantic scale. Two processes are employed for obtaining soda, one of these being known as Leblanc's and the other, which is of comparatively recent date, as the Ammonia soda process.

Leblanc's process was first made known to the world by a commission of the French republic in 1794, although dating some years earlier. It has been one of the most valuable discoveries in the entire range of chemical manufactures, and has been practised for a century without any important alteration. The author of this invention reaped no benefit from it himself, but spent the last of his days in an hospital, 'a wreck in fortune, health, and hope.' Owing partly to the war between France and England, and partly also to the existence of a duty of £30 per ton on common salt, which continued for eight years after the close of the war, Leblanc's process was not adopted in Great Britain except on a very limited scale till 1823. After the repeal of the tax in that year Mr James Muspratt erected his celebrated works at Liverpool, adopted the process in its entirety, and succeeded, after overcoming many difficulties, in establishing this great industry in Great Britain. The object of the process is (1) to convert common salt by the action of sulphuric acid into sulphate of soda (sodium sulphate); (2) to reduce this sulphate to the sulphide of sodium by the abstraction of oxygen; and (3) by certain reactions, in which carbonate of lime (calcium carbonate) takes part, to produce either carbonate of soda (sodium carbonate) or caustic-soda. The several stages are as follows.

Production of Salt-cake or Sulphate of Soda (*Sodium Sulphate*).—The decomposition of common salt is effected by treating it with sulphuric acid, which converts it into sulphate of soda and hydrochloric acid, thus:



The reaction is represented by the equation

$$2NaCl + H_2SO_4 = 2HCl + Na_2SO_4.$$

This operation was long conducted in a reverberatory furnace, which allowed the gaseous hydrochloric acid produced to escape into the air, to the destruction of all vegetation in the neighbourhood. Fig. 1 will serve as a diagram to explain the nature of the salt-cake furnace, called a *blind roaster* or *muffle-furnace*, for making salt-cake. A is the iron pan in which the charge of common salt and sulphuric acid is first placed, and B is the muffle in which the calcination of the half-finished sulphate is completed, the charge being raked from A into B. The fire (C) heating

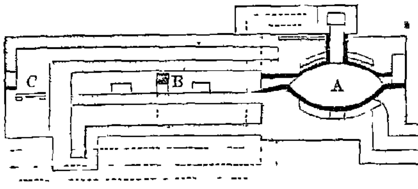


Fig. 1.—Vertical Section of Furnace for making Sulphate of Soda.

the muffle is so placed that the fire gases do not get inside, but heat it by external flues. Usually the pan is heated by a separate fire, but in some instances by the waste heat from the muffle fire. The gaseous hydrochloric acid evolved during the time the reaction between the salt and the sulphuric acid is going on in the pan is sometimes led away to a separate condenser; but if a comparatively pure acid is not required then the gases from both pan and muffle go into the same condenser.

In the case of the *open roaster*, an older kind still used, there is a direct opening from the fire into the bed of the furnace, which is then of an ordinary reverberatory type (see COPPER, fig. 1, and LEAD, fig. 1), with the pan placed at the end as in the blind-roaster; but in this case the pan has always a separate fire. Coke is generally used for fuel in the open roaster, and with it the pan gas is usually separately condensed. Each of these kinds of furnaces has its advantages and disadvantages. The usual charge for open roasters is about 9 cwt. of common salt, and for close roasters one-half more. With the equivalent quantity of sulphuric acid 100 parts by weight of pure chloride of sodium would theoretically yield 121·45 parts of sulphate of soda, but in practice only about 110 are obtained, owing to the presence of moisture in the common salt. The specific gravity of the sulphuric acid employed varies from 1·700 to 1·720.

Rotating furnaces for making sulphate of soda have been introduced in recent years, the one patented in 1875 by Jones and Walsh being the first which came into actual operation. It has since been improved by the patentees and others, and is now in use at several large alkali-works. Fig. 2 is a diagram of this furnace. It consists of a rotating iron pan, 16 feet and upwards in diameter, placed in a chamber arched over with firebrick. From the fireplace at one side the fire gases pass over the surface of the charge to the flue at the other side. The salt is admitted by a hopper closed by a balanced cone, and there are lead-pipes for admitting the sulphuric acid at the edge of the pan. Fixed stirrers or ploughs are used for turning over the charge, which, in the largest sized pans, is now sometimes as much as 25 tons of common salt, and this with 20 tons of sulphuric acid gives 27 tons of sulphate of soda every twelve hours. Gas from a producer is sometimes used to heat the furnace, and a self-acting method of emptying the pan was patented by the inventors in 1880. There is a great saving of manual labour by the use of this furnace. Sulphate of soda, although chiefly consumed as an intermediate product in alkali making, is used by itself in glass-making, in the manufacture of ultramarine, for cold-producing mixtures, and for making various chemicals.

From any of these salt-cake furnaces the hydrochloric acid gas is led away by pipes or flues to *condensing towers sometimes 100 feet high, and* filled with pieces of coke. The acid vapour enters at the bottom of the tower, and in ascending through the piled coke meets with a descending stream of water from the cistern on the top by which it is absorbed, and flows away as liquid acid through a pipe at the base of the tower to stock-cisterns. Strong hydrochloric acid, which is chiefly used in the manufacture of Bleaching Powder (q.v.), is easily obtained by good condensing appliances either from the rotatory pan furnace or *from the pan of a stationary furnace*, but the acid from the roaster gas is usually weak. The Alkali Acts of 1863 and 1874 make the condensation of nearly the whole of the gaseous hydrochloric acid produced at soda-works imperative.

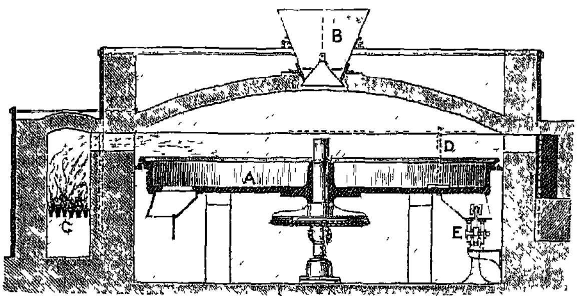

Fig. 2.—Rotating Furnace for making Sulphate of Soda: A, iron pan for containing charge; B, hopper, with balanced cone for charging; C, fireplace; D, one of the stirrers; E, self-acting arrangement for discharging pan.

Conversion of the Sulphate of Soda into Black-ash.—The sulphate of soda is roasted with coal and limestone to produce crude carbonate of soda. In this operation the oxygen of the sulphate combines with carbon furnished *by the coal to form* carbonic oxide, which escapes into the air. The remaining sodium sulphide interchanges combinations with the carbonate of lime (limestone), forming carbonate of soda, easily soluble in water, and calcium sulphide, which is insoluble. The action of the carbon in reducing the sulphate of soda to the sulphide is shown by the equation

$$Na_2SO_4 + C_4 = Na_2S + 4CO.$$

The further change which occurs is thus represented:

$$Na_2S + CaCO_3 = Na_2CO_3 + CaS.$$

The proportions of the materials as now used are the same as those first recommended by Leblanc—viz. sulphate of soda, 100 parts; carbonate of lime (limestone), 100 parts; carbon (charcoal), 55 parts. But as coal is employed in England instead of charcoal, the quantity used is generally 75 to 100 of each of the other two ingredients. The 'balling furnace' used in this operation is shown in fig. 3. It has two beds, the one being raised a few inches above the other. F is the fireplace, the waste heat from which is usually employed in boiling down the tank liquor or soda-lye as indicated in the section. The charge of about 8 cwt. of the above mixture is thrown into the bed, A, of the balling furnace, after it has been raised to a bright red heat, and remains till it becomes sufficiently heated throughout the whole mass. It is then transferred to the *fluxing bed*, B, which is next the fire, and exposed to a higher heat, when it shortly begins to soften and flux into a mass like dough. In about fifty minutes the charge is withdrawn in a red-hot state by the working door, and received into iron barrows, where it solidifies into blocks of crude soda, termed ball soda or black-ash.

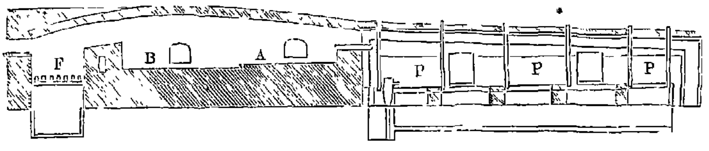

Fig. 3.—Section of Balling Furnace, showing an evaporating pan, P, P, for Soda-liquor in connection with it.

Black-ash is now extensively made in a revolving furnace, which does away with the arduous manual labour required in a stationary furnace, and which was first patented in 1853, though many difficulties had to be overcome before it became a success. Mr J. C. Stevenson, of the Jarrow Chemical Works, after much labour succeeded about 1870 in establishing its superiority over the older kinds of balling furnaces. A longitudinal section of this furnace is shown in fig. 4. It is either cylindrical or barrel-shaped, about 18 feet long and 10 feet in diameter, lined with firebrick. The furnace is driven by steam and the necessary gearing, a spur-wheel being placed round and fixed to the cylinder, which turns on friction rollers. At one end it is furnished with a large fireplace, the fire gases from which pass through the 'barrel,' and onwards to heat the boiling-down pans, which are placed at the opposite end and arranged much in the same way as in the stationary furnace. The larger-sized revolving furnaces produce 30 tons of black-ash in twenty-four hours.

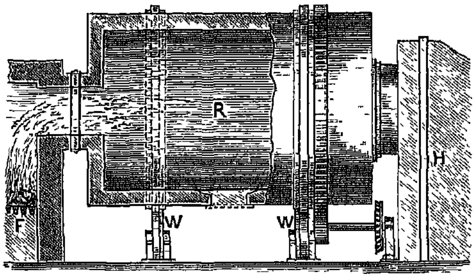

Fig. 4.—Revolving Black-ash Furnace, partly in section: F, fire; R, revolving cylinder; W, friction wheels; H, tanks, &c., for evaporating soda-lye by waste heat of furnace.

Lixiviation of the Black-ash.—The crude soda so named requires to be porous, so that water will easily penetrate the broken lumps of it when placed in iron tanks. Formerly a series, say of four of these, was placed in a step-like arrangement in which the lowest contained the fresh black-ash and the highest that which was nearly exhausted of its soda. Fresh water flowed in at the top, and, as it dissolved out the soda, became gradually stronger in descending from tank to tank, till it reached its full strength in the lowest one. A more recent plan is to have the tanks all on a level and communicating with each other by tubes; but the exhaustion of the black-ash takes place in a similar way. Weak soda liquor is present in the tank with the nearly exhausted ash, and strong liquor in the one containing fresh black-ash, while the other two have liquors of intermediate but unequal strengths. The level of the liquor differs in each, being highest where weakest and lowest where strongest. When communication is opened between these tanks circulation is caused by hydrostatic pressure. The soda liquor from the black-ash is treated differently, according to whether soda-ash or caustic-soda is to be made from it.

Caustic-soda.—As the tank liquor consists of a strong solution of carbonate of soda, it requires to be diluted before it can be causticised with lime. Long iron cylinders contain this diluted liquor, into which lime is placed, and at the same time it is heated and agitated. After being allowed to settle, the clear liquor is drawn off and pumped into liquor-settlers, the lime mud in these being saved and used in the black-ash furnace. Several iron concentrating cisterns are successively used with the aid of heat to bring up by degrees the causticised soda liquor to the required strength. From the last of these cisterns (boat-pans) the liquor, having a specific gravity of 1·550, is run into cast-iron pots, each of a capacity of 10 tons, which are heated by strong fires, and here the concentration of the liquor is completed, and the caustic-soda ladled into sheet-iron 'drums' containing 6 cwt. each. On cooling it solidifies into a white mass of sodium hydrate or caustic-soda, NaOH, which is now manufactured in large quantities, containing as much as 77 per cent. of sodium monoxide, Na_2O. During the concentration nitrate of soda is used to decompose any sodium sulphide present in the liquor. Caustic-soda is most largely used in soap-making and paper-making, but also in the manufacture of some coal-tar dyes and oxalic acid.

Soda-ash.—When this substance (carbonate of soda) and not caustic soda is to be made, the black-ash liquor is differently treated. In referring to the black-ash furnaces (see figs. 3, 4) it has been stated that their waste heat is used to boil down the black-ash liquor. As the concentration of the liquor proceeds granular crystals of soda are deposited and scraped out into drainers. When heated these crystals yield soda-ash; but impure soda remains in the boiling-down vessel. This soda, which is mostly carbonate but also contains caustic-soda and sodium sulphide, is mixed with some sawdust and evaporated to dryness. The black-salt, as this residual substance is called, is then heated in a carbonating oven in which the burning off of the sawdust generates carbonic acid, and this converts the caustic-soda and sodium sulphide present into carbonate, and soda-ash is the result. The composition of commercial soda-ash is very variable, but it frequently contains about 80 per cent. of the carbonate, the remainder consisting of other compounds of sodium and small quantities of other substances. None of these, however, interfere with its use for the purposes for which it is usually employed. When it is sold the available percentage of soda (sodium oxide or Na_2O) is quoted. For certain purposes soda-ash is refined by dissolving, settling, evaporating, and calcining. It is then called *refined* or *white alkali*, which should be free of caustic-soda and contain no trace of sodium sulphide, sodium sulphite, or of iron.

Crystals of Soda, Washing-soda, $Na_2CO_3, 10H_2O$.—The soda-ash used for making soda-crystals is previously calcined and dissolved in hot water in iron vessels, the solution being then allowed to cool.

From this solution large crystals of almost pure carbonate of soda separate. Ordinary washing-soda consists of these crystals, which are of uniform composition and easily dissolved. They contain ten molecules of water—that is to say, they are composed of 37 per cent. of carbonate of soda and 63 per cent. of water. Crystal soda being quite free from caustic-soda and other compounds acting on the skin, the hands of washerwomen suffer less from it than from other kinds of alkali.

Bicarbonate of Soda, $2NaHCO_3$.—As will be presently explained, this salt is now prepared on a large scale as a stage in the ammonia-soda process. See SODIUM.

Sulphur Recovery.—The recovery of sulphur from the exhausted black-ash, which forms the waste heaps of the alkali-maker, is now, after many unsuccessful attempts to do so economically, practised on a large scale by Chance's process patented so recently as 1888. This residue, as has been stated, is essentially calcium sulphide, which when brought into contact with carbonic acid in the presence of water is converted into carbonate of lime, and sulphuretted hydrogen is liberated. The practical difficulty had long been the getting of hydrogen sulphide in a sufficiently concentrated state. Mr Chance's process is as follows: The vat mud (black-ash waste) has the coarser extraneous pieces removed by a sifting process, and is then made into a creamy consistency with water. In this state it is distributed into a series of cylindrical iron vessels for the purpose of having carbonic acid passed through it. These cylinders have three main pipes passing over them, with branches to each. By one pipe the carbonic acid is introduced at the bottom of the liquid, and the other two lead the gases away from the top of the cylinder.

The carbonic acid is produced in a limekiln, and passes, unavoidably mixed with nitrogen, into the cylinders, which successively become richer in sulphur compounds. The result is that for a time little else than nitrogen comes away from the last cylinder. But when the reactions in the cylinders are completed the final vessel of the series gives off gas rich in sulphuretted hydrogen. By means of stopcocks one of the pipes at the top of each cylinder conveys the nearly unmixed nitrogen to an open chimney, and the other takes the rich mixture of nitrogen and sulphuretted hydrogen to a gasholder. When the carbonic acid from the limekiln passes into the first cylinder containing the black-ash waste, carbonate of lime is produced with evolution of sulphuretted hydrogen, H_2S. The latter passes on with the excess of nitrogen into the second cylinder, where there is formed sulphydrate of calcium, CaH_2S_2, which is a compound of H_2S and CaS. In this way we have the sulphur concentrating from first to last in the series of cylindrical vessels until it is finally expelled as sulphuretted hydrogen gas. In the process the carbonic acid combines with the calcium of the sulphydrate, giving off the two atoms of sulphur as H_2S, so that for a given amount of carbonic acid used we get a double quantity of sulphur. All the time the vessels at the beginning of the series remain unsaturated, the nitrogen, amounting to about 70 per cent. of the gases pumped in, passes away in pipes, and is allowed to escape. It contains little or no sulphur; but by-and-by the gas in the vessels consists of from 30 to 35 per cent. of sulphuretted hydrogen and from 1 to 2 per cent. of carbonic acid, the remainder being nitrogen. This mixed gas is collected in a gasholder to enable it to be treated as required. The carbonated mud left in the vessels is drained, and used in place of limestone in the black-ash furnaces, so that any soda this dried mud contains is recovered.

The sulphur is obtained from the gas in the gasholder in a very pure state in cakes and flowers of sulphur by this operation. A definite mixture of the sulphuretted hydrogen (present in this gas) and air is passed through a layer of anhydrous oxide of iron in a Claus kiln, the oxygen present being only enough to unite with the hydrogen (of the H_2S) to form water, the sulphur being set free. Iron oxide has the power of producing the combination without itself suffering change, the bed of this material becoming (without the use of fuel) sufficiently hot, by the chemical change which goes on, to volatilise the sulphur vapour along with the steam produced. The change is represented by the formula $H_2S + O = H_2O + S$. But the sulphuretted hydrogen may also be itself burned to make vitriol, which is obtained of the same purity as when made from sulphur.

The Ammonia-soda process has within the last few years come into competition with and threatens to supersede that of Leblanc. It is based on the mutual reaction which takes place at ordinary temperatures between common salt and bicarbonate of ammonia in strong aqueous solutions. The sodium of the salt combines with the carbonic acid and the chlorine with the ammonia, giving bicarbonate of soda, which is insoluble, and chloride of ammonium, which remains dissolved in the liquid, thus:

$$NaCl + (NH_4)\,HCO_3 = NH_4Cl + NaHCO_3.$$

The ammonia is recovered from the chloride and one-half of the carbonic acid from the bicarbonate for future use. Where possible natural brine is used, and this is brought to a specific gravity of nearly 1200, either by the addition of salt if too weak or by adding water if too strong. Ammonia in the free gaseous state is now passed into the brine until the required quantity is present, which is known by the amount of increase in the volume of the liquid. The ammonia enters a mixing tank under a perforated diaphragm, and the liquid is kept in agitation. A great rise of temperature is caused by the condensation of the gaseous ammonia, and this necessitates the running of a stream of water through a coil of piping inside the mixer to keep the heat as low as possible. The brine in running off passes through a filter to retain solid impurities, and then through another worm of piping surrounded by cold water. To form the bicarbonate of soda the ammoniacal brine requires to be saturated with carbonic acid. Air-pumps draw the carbonic acid from a limekiln and force it (after being properly cooled) at a pressure of nearly two atmospheres in at the bottom of a tower 50 feet high, which is kept nearly full of the liquid. This tower has perforated plates at every three feet of height to make sure that the gaseous bubbles are spread equally through the liquid. Every half-hour some of the pasty mixture in the tower is run off at the bottom. This is full of the small crystals of bicarbonate of soda, and these are separated by running the mass over a wire-gauze filter covered by a cloth, a vacuum being maintained below. The bicarbonate of soda on the filter is nearly pure, and the liquid which passes through is ammonium chloride. The bicarbonate thus obtained is washed with water and carefully dried in apparatus of which there are various forms. As there is a comparatively limited demand for this kind of soda, it is afterwards heated in close vessels in which half of its carbonic acid is given off, thereby reducing it to the normal or common carbonate of soda (soda-ash). The gas given off is pumped back to the tower and used along with the kiln gas for carbonating fresh material. To expel any ammoniacal salts adhering to the carbonate of soda and render it denser for packing, the heat is continued until fusion takes place. The ammonia is recovered from the liquid filtered from the bicarbonate of soda by heating it with lime. After the ammonia is driven off by heat the remaining liquid is calcium chloride, which is generally run to waste.

See Lunge's *Treatise on the Manufacture of Sulphuric Acid and Alkali* (1880); Diagram, with Key of the Leblanc Soda Process, by J. J. Miller, 1891 (for students); *Journal of Chemical Industry* (vol. for 1888), containing a paper by Mr Chance on Sulphur Recovery.

Soda Water. See AERATED WATERS.

Söderhamn, a seaport of Sweden, on a bay of the Gulf of Bothnia, 13 miles N. of Gefle, exports some 250,000 tons of iron and timber (in 600 vessels) annually. It has been frequently burned down, the last time in 1865. Pop. 9044.

Sodium (sym. Na; equiv. 22·29; sp. grav. 0·973) is one of the metals of the alkalies, its oxide being soda. Its properties closely resemble those of the allied metal potassium. It is of a bluish-white colour, is somewhat more volatile than potassium, and further differs from that metal in having a higher fusing-point—about 208° (97° C.), a greater specific gravity, and in not catching fire when dropped in water (unless the water is heated), although, like potassium under similar conditions, it partially decomposes it and liberates hydrogen, and at the same time communicates a strong alkaline reaction to the solution. If, however, a piece of unsized paper is placed on the surface of cold water, and the sodium is placed on the paper, the metal takes fire and burns with a deep yellow flame. Strictly speaking, it is the liberated hydrogen rather than the metal which burns; but a little sodium, volatilised by the heat, burns with the hydrogen. When heated in the air it burns with its characteristic yellow flame, and is converted into soda. When exposed *in vacuo* to a red heat it assumes the form of vapour, and admits of distillation. Like potassium, it must be kept immersed in naphtha, so as to exclude the oxidising action of the air. As a reducing agent it is little inferior to potassium; and as its combining power is lower, and it is obtained much more cheaply, it may usually be advantageously substituted for potassium in reducing operations. Sodium does not occur in the metallic form in nature, but its compounds are very widely distributed. It is found by far the most abundantly in the form of chloride of sodium (or common salt), but it likewise occurs as albite or soda felspar, cryolite (the double fluoride of sodium and aluminium), borax (the biborate of soda), trona (the sesquicarbonate of soda), and Chili saltpetre (nitrate of soda). Duhamel in 1736 discovered that potash and soda (now known to be the oxides of potassium and sodium) were distinct bodies. Sir H. Davy first obtained the metal *Sodium* in 1807. The symbol of this metal, Na, is the abbreviation of *Natrium*, which is derived from *Natron*, one of the old names of native carbonate of soda.

The methods of obtaining sodium are similar to those already described for obtaining potassium. Intimately mix 30 parts of common soda-ash with 13 parts of small coal and 3 parts of chalk, knead them into a stiff paste with oil, heat them in a covered iron pot till the oil is decomposed, and finally distil them in an iron retort with the precautions which are noticed in describing the preparation of potassium. The object of adding the chalk is to prevent the separation of the charcoal from the carbonate of soda when the latter fuses. This mixture ought to yield nearly one-seventh of its weight of sodium.

Sodium combines with all the elementary gaseous bodies, and two of these combinations, those with oxygen and chlorine, are of extreme importance and value. With *oxygen* sodium forms two compounds—an oxide, Na_2O, and a peroxide, Na_2O_2. The latter is of no practical value. The oxide (soda) was formerly known as *fossil* or *mineral alkali*, to distinguish it from potash, which, from the source from which it was procured, was termed *vegetable alkali*. Anhydrous soda, Na_2O, is procured by burning the metal in dry air; it is of a yellowish-white colour, powerfully attracts moisture, and retains the water so firmly that it cannot be expelled by heat. Hydrated or caustic soda, $NaHO$, closely resembles, both in its properties and in the mode of procuring it, the corresponding potash compound. It is, however, not so fusible as the latter, and is gradually converted, by exposure to the air, into carbonate of soda, which is also an infusible salt in its anhydrous state. Solution of hydrate of soda (or soda lye) is largely employed in the arts. It is prepared by boiling a tolerably strong solution of carbonate of soda in milk of lime until a portion of the filtrate ceases to effervesce on the addition of an acid. The solid hydrate has a specific gravity of 2·13, and the quantity of anhydrous soda in any solution may be closely approximated to by determining the specific gravity of the fluid and referring to a table indicating the strength corresponding to the specific gravity.

Many of the combinations of the oxide of sodium (soda) with acids—constituting soda-salts—are of great importance. Carbonic acid forms three salts with soda—a normal carbonate, a sesquicarbonate, and a bicarbonate of soda.

Carbonate of Soda, $Na_2CO_3 + 10H_2O$, the *Soda* of commerce, is a colourless, inodorous salt, with a nauseous alkaline taste. It crystallises in large transparent rhomboidal prisms, which contain nearly 63 per cent. of water, but it readily parts with all this water on the application of heat. The crystals also lose the greater part of their water on mere exposure to the air, when they effloresce, and fall to powder. Water at 60° (15° C.) dissolves half its weight of the crystals, and boiling water considerably more, the solution acting like an alkali on vegetable colours. This salt, the *natron* of commerce, occurs native in the natron-lakes of Hungary, Armenia, &c., in association with sulphate of soda and chloride of sodium. In other regions it appears in an efflorescent form on the surface of the earth. It is now, however, almost entirely manufactured from sea-salt. For its manufacture, see SODA.

Sesquicarbonate of Soda, $Na_2CO_3 + 2NaHCO_3 + 3H_2O$, occurs native in the form of large, hard, non-efflorescent prisms, in Hungary, Egypt, Mexico, &c., under the name of *Trona*. When strongly heated it loses one-third of its carbonic acid, and becomes converted into the preceding salt.

Bicarbonate of Soda, $NaHCO_3$, may be formed by passing a current of carbonic acid through a strong solution of carbonate of soda, till saturation takes place, and allowing the mixture to crystallise; or it may be produced on a large scale by exposing crystals of carbonate of soda to a prolonged current of carbonic acid. Most of the bicarbonate in commerce is now, however, prepared by the ammonia-soda process (see SODA). In this a current of carbonic acid gas is passed through a solution of salt in aqueous ammonia, when chloride of ammonium and bicarbonate of soda are produced. The bicarbonate crystallises in four-sided prisms, which require 10 parts of water at an ordinary temperature for their solution. This salt is used largely in medicine. See AERATED WATERS.

Sulphuric acid forms with soda a normal and an acid sulphate. The normal *Sulphate of Soda*,

$Na_2SO_4 + 10H_2O$, has been already described under its synonym of *Glauber's Salt* (q.v.). The acid salt, or *bisulphate* of soda, $NaHSO_4$, is of no special interest.

The *Hyposulphite of Soda*, $Na_2S_2O_3 5H_2O$, occurs *in large colourless, striated, rhombic prisms, of a* cooling and sweet taste. When strongly heated in the air it burns with a blue flame. It dissolves readily in water, depositing sulphur if the solution be kept in a closed vessel. It may be obtained by digesting a solution of sulphite of soda with powdered sulphur. The sulphur is gradually dissolved, *and forms a colourless solution*, which, *on evaporation*, yields crystals of hyposulphite of soda. This salt is largely employed in photography, and is occasionally prescribed medicinally. Sulphurous acid forms two salts with soda—viz. a sulphite and a bisulphite. The *Sulphite of Soda*, $NaHSO_3 + 7H_2O$, is obtained by passing sulphurous acid over carbonate of soda, *dissolving the resulting mass* in water, and crystallising; when the salt is obtained in efflorescent oblique prisms, which are soluble in 4 parts of cold water, the solution having a slightly alkaline reaction and a sulphurous taste. This compound was at one time commercially known as *Antichlore*, and was largely used in paper-manufactories for the purpose of removing the last trace of chlorine from the bleached rag-pulp. The term is now applied only to the hyposulphite, which is both cheaper and more efficacious. The *Bisulphite* is of no importance. *Nitrate of Soda*, $NaNO_3$, known also as *Cubic Nitre* or *Chili Saltpetre*, occurs as a natural product on the surface of the soil of certain South American districts. In most of its properties, excepting its crystalline form, and further in its being deliquescent, it resembles nitrate of potash. It is used as a Manure (q.v.). The *Phosphates of Soda* are comparatively numerous. *Hypo-chlorite of Soda*, $NaClO$, is at present known only in solution, in which it occurs as a yellowish-green fluid, evolving a smell of chlorine; it has strong bleaching power, and when boiled becomes decolorised, and evolves chlorine freely. It is formed by passing a stream of chlorine gas through a solution of carbonate of soda, the resulting solution containing the hypochlorite, together with undecomposed carbonate of soda and chloride of sodium. This solution is useful as a bleaching agent, as an oxidising agent in analytical chemistry, and as a disinfectant agent. There are two *Borates of Soda*, of which the only important one, the *Biborate*, is already described under its ordinary name of *Borax* (q.v.). Various *Silicates of Soda* have been formed (see SILICON, GLASS, SLAGS).

The *Haloid Salts* of sodium resemble, in their general characters, the corresponding salts of potash. Of these by far the most important is *Chloride of Sodium* or *Common Salt*, formerly known as *Muriate of Soda*, $NaCl$. It occurs naturally *in far greater quantity* than any other soluble salt, and is fully described at SALT. The other haloid salts—the iodide, bromide, and fluoride of sodium—require no notice.

Sodium has been recently found to enter into various groups of organic bodies—the sodium-alcohols for example. When sodium or potassium *is gradually added to anhydrous alcohol the temperature* rapidly rises, the metal is dissolved, hydrogen is evolved, and a fusible deliquescent compound is formed, which has received the name of *Sodium-alcohol* (or potassium-alcohol), or of *ethylate of soda* (or potash), its composition being such that it may be regarded as alcohol in which one atom of hydrogen is replaced *by one of the metal.*

The *tests* for the salts of sodium are not very satisfactory, because the metal forms scarcely any insoluble compounds. A salt of sodium is usually concluded to be present when, the absence of all other bases having been proved, a saline residue remains, which, with bichloride of platinum, yields yellow striated prisms by spontaneous evaporation. Before the blowpipe the salts of sodium are known by *the intense yellow which they communicate to* the outer flame, and if a weak alcoholic solution of one of the salts is burned a similar yellow tint is communicated to the flame. Spectrum analysis is too delicate to be of much practical use.

The *medicinal uses* of the sodium compounds may be considered alphabetically. *Acetate of Soda is a mild diuretic, similar in operation to* acetate of potash, for which it may be substituted. *Arseniate of Soda* is serviceable in periodic affections, chronic skin diseases, and the cases in which arsenic is generally employed in medicine. Paper impregnated with a solution of arseniate of soda sweetened with sugar is sold as a poison for flies. *Biborate of Soda*, or *Borax*, *is employed principally* as a topical astringent, and is used with advantage in aphthous eruptions of the mouth and throat. *Bicarbonate of Soda* is a most popular remedy in cases of dyspepsia, but its use is highly injurious when there are phosphatic deposits in the urine. *Carbonate of Soda* is not employed as an antacid so *frequently* as the *bicarbonate, in consequence of its* disagreeable taste; but in the dried state, when deprived by heat of its water of crystallisation, it is much used as an alterative. In dyspepsia attended with acidity a combination of the dried carbonate with blue pill and rhubarb pill is often extremely useful. As it has a very acrid taste, *it should be combined, if given in powder, with* some bland substance, such as Compound Tragacanth Powder. A solution of *Chlorinated Soda* is preferable to hypochlorite of lime in destroying noxious effluvia, as the salt which is left does not deliquesce. *Phosphate of Soda*, known also as Tasteless Purging Salt, is a mild saline purgative, with a far less unpleasant taste than sulphate of magnesia. *Sulphate of Soda* and *Tartrate of Soda and Potash* have been already described under their ordinary names of Glauber's Salt (q.v.) and Rochelle Salt (q.v.).

Sodom, APPLE OF, the name given to the *fruit of a species of Solanum* (q.v.). *But it is* possible that the true Apple of Sodom, or Mad Apple, of the shores of the Dead Sea, mentioned by Strabo, Tacitus, and Josephus, and described as beautiful to the eye, but filling the mouth with bitter ashes if tasted, is a kind of gall growing on dwarf oaks, and produced by a species of gall-insect.

Sodom and **Gomorrah**, two ancient cities, almost invariably spoken of in conjunction in the Bible, and forming with Admah, Zeboiim, and other towns the 'cities of the plain,' which, on account of the enormous wickedness of their inhabitants (the nature of which is indicated in the term Sodomy), are said to have been overthrown—not submerged—by some terrible convulsion of nature. Modern writers on sacred topography are not agreed as to the site to be assigned to these cities. It used to be generally held that they stood on the southern shore of the Dead Sea, near *the salt ridge of Usdom (a form of the word* 'Sodom'). Conder believes, however, that he can fix the site of Zoar, at least, at the foot of the mountains of Moab, to the north-east of the Dead Sea (q.v.). The popular belief that the cities were miraculously overwhelmed by the waters of the Dead Sea, and that their remains may still be *seen at the bottom, is an idle tale of superstitious* travellers, uncountenanced either by fact or by the terms employed by Scripture to describe the catastrophe.

Sodomy, an unnatural crime, is punishable with penal servitude for life, or any term not less than ten years, and the attempt to commit it is punishable with penal servitude from three to ten years. In Scotland it was till 1887 nominally a capital offence, though not punished except by penal servitude and imprisonment.

Sodor and Man. See HEBRIDES, and MAN.

Soest, a town of Westphalia, 37 miles SE. of Münster by rail, was during the middle ages one of the most important of the Hanse towns, and a free imperial city, with a population of 30,000. Now it is a place of little importance, with only 14,846 inhabitants. The principal survival of its ancient splendours is the Gothic 'Meadow Church,' built in 1314, but restored in 1846. There is also a Roman Catholic cathedral. The municipal law of Soest, the *Jus Susatense*, served as the model for Lübeck, Hamburg, &c. In 1180 the Archbishop of Cologne seized the sovereignty of the town; but in 1441 the people rose against the archbishop's rule and put themselves under the protection of the Duke of Cleves. This gave rise to the 'Feud of Soest,' in the course of which the town was closely besieged and heroically defended, the women especially distinguishing themselves.

Sofala, the name given to that portion of the south-east coast of Africa which extends from the Zambesi as far south as Delagoa Bay. The inland region at the back of the coast district, now occupied by the Transvaal Boers towards the south and by the Matabele to the north, formed the celebrated though mythical empire of Monomotapa. Sofala was described by the old geographers as a very rich, gold-producing country, and was judged by some to be the Ophir of Solomon, an idea afterwards long discredited, but lately revived since Mauch discovered the disused mine-workings around Zimbabwe (q.v.), and interest was aroused in them through the British South Africa Company penetrating into that region. Sofala belongs to the Portuguese, who established themselves here in 1505. Their headquarters, the town of Sofala, once a large commercial town, is now a wretched place of 1000 inhabitants.

Sofia, the capital since 1878 of the principality of Bulgaria, stands in a broad valley of the Balkans, beside the railway connecting Constantinople with Belgrade and Vienna. The city since 1891 has undergone thorough reconstruction, most of the crooked dirty streets, with their tumble-down houses and ruinous mosques, of the old Turkish city being demolished to make way for broad tree-planted boulevards, with paved sidewalks and electric-light posts, new French-looking houses, shops and hotels, and large public buildings (baths, national library, banks, post-office, &c.). The principal streets converge upon the new government palace. For centuries the place has been renowned for its hot mineral springs (117° F.). Sofia is the seat of a metropolitan of the Greek Church, and of the national university. There is a considerable trade in hides, spirits, maize, and wheat. Pop. (1870) 19,000; (1888) 30,428, of whom two-thirds were Bulgarians, and about 5000 Jews (originally emigrants from Spain). Sofia is the *Serdica* of the Romans, and was the seat of a famous church council in 343. Attila plundered it; and it was in the possession of the Bulgarians from the beginning of the 9th century until its capture by the Turks in 1382. Both Hunyady and the Albanian chief Mustapha Pasha (in 1829) utterly devastated the place, and it was occupied by the Russians under General Gourko in January 1878. See *Contemporary*, April 1891.

Softa, a student of Mohammedan theology and sacred law.

Soft-grass (*Holcus*), a genus of Grasses (q.v.).

Sogdiana, anciently a province of the empire of Persia in the time of the Achæmenians, corresponded to the modern districts of Samarcand and Bokhara and the valley of Zerafshan. Under the Greeks, after its conquest by Alexander the Great, it was united with Bactria. The Arab geographers describe its fertility and beauty in terms of exaggerated eulogy.

Soham, a small market-town of Cambridgeshire, with a fine church, 5 miles SE. of Ely. Pop. of parish, 3980.

Sohar, a seaport of Oman in Arabia, stands on the Gulf of Oman, 130 miles NW. of Muscat, and is a well-built place with town-walls and a castle, some weaving and working of metals, a good harbour, and an active trade. It was a famous trading-town in the end of the 10th century, but not long after its commerce fell away entirely. The Portuguese occupied it from 1508 to 1650. Pop. probably 5000.

Soignies, a town of the Belgian province of Hainault, 22 miles by rail S. by W. of Brussels. The church of St Vincent dates from the 12th century, though it was first founded in 650. Pop. 8683. Near here the French defeated the Netherlanders on 10th July 1794.

Soils. Soils are generally said to be derived from our primitive rocks by that disintegrating process called weathering (see DENUDATION). The doctrine that commonly obtains is that lichens, the first occupants of the thin initial layer so formed, contributed by their life and death in turn to soil formation, and thereby made life possible for the mosses. These in like manner yielded their increase, and rendered it possible for plants of a still higher order to grow and flourish, and so on, until perfect soils were produced in which all plants might luxuriate. It is perhaps convenient to adopt the lichens as the starting-point; but it would probably be more accurate to presume that these were preceded by other forms, for the origin of soils may indeed have been the origin of life itself, and until we can clearly define the one there must of necessity be indefiniteness about the other. Recent experiments go to show that sterilised soils are infertile soils; and if that be an unassailable doctrine, then it follows that micro-organisms aided in the formation of that soil which was sufficient for the growth of the lichen. The origin of soil organisms must be left to the bacteriologist to discuss, but it may not be out of place to state here that the growing, sowing, and feeding of the desirable soil germs is of as much importance to the agriculturist of to-day as is the sowing of seeds, or the growing and feeding—by manuring—of plants; indeed, it may almost be asserted that manures applied to soils do not always act—as they do in water-culture experiments—as direct plant-food, but rather as food for those soil bacteroids which are the great agricultural workers, or preparers of food for plants. It may be affirmed that it is quite as necessary for the agriculturist to have certain conditions of soil—physical and chemical—which are essential to the growth and working of the desirable germs, and accordingly essential for the growth of good crops, as it is for the brewer to have those more or less definite physical and chemical conditions which are essential to the growth and working of the yeast plant in the production of good beer. Moreover, what is universally stated in text-books as being due to a 'selective power' of plants is entirely ascribable to the biological condition of the soil; and far from its being a power of selection or instinct possessed by plants, these have no choice in the matter.

Popularly speaking, the breaking down of rocks—by weathering—results in the building up of soils, and the composition of soils so formed must vary in proportion to the kind and number of minerals employed in the process. The principal minerals so employed are felspar, quartz, mica, talc, limestones (including chalks, marls, &c.), hornblende (amphibole, augite, olivine, &c.), clays, and zeolites. Soils formed from the rocks underlying them are designated *sedimentary*, while *transported* soils are those derived from rocks at higher levels: thus, if carried down by glaciers they are termed *drift soils*, if carried by running water they are known as *alluvial soils*, and the combination of these two agents results in *co-alluvial soils*. Anderson classified soils according to 'their general physical characters, and the ordinary mode followed in practice of dividing them into clays, loams, &c.' They are also frequently classed thus: siliceous or sandy, calcareous, argillaceous, and vegetable or peaty, while a somewhat elaborate subdivision of these is given in Schubler's classification.

Generally speaking, a mixed soil will possess important advantages over clay, chalk, or siliceous soils, and this mixing is performed by nature herself, as already described, where there is a dual outcropping of rocks; while the art of man effects what is practically the same thing by claying, liming, marling, &c. The chemical composition and physical conditions of soils have until quite recently been about the only features which received consideration, but it is now beyond doubt that the biological condition is of at least equal importance, for, in regard to a well-drained soil, *sterility* and *infertility* are synonymous terms. This new doctrine solves at once the problems which for many generations have been insurmountable—in such cases, for instance, as two soils having the same *chemical* composition, and one being fertile and the other barren. Another highly important consideration is that sterile soils are practically *non-retentive;* and if that be so, all the hitherto obtaining doctrines which have ascribed to silicates, oxides, &c. such unerring precision in forming new and definite but purely chemical relationships with added substances, such as phosphates, potash and ammonia salts, &c., must fall. It has been (and is still) customary for exponents of agricultural science to remark that it was a curious thing that the valuable nitrates were *not retained* by soils—were indeed easily washed out, and were more or less always to be found in drainage waters, while phosphoric acid, potash, or ammonia was rarely if ever so; but according to the germ theory there is nothing curious about it, and it could not be otherwise in a fertile soil. It is evident that many of the heretofore established certainties of soil science and of agriculture are destined to be overthrown. Capillarity, for instance, is doomed; for fertility of soil is incompatible with that condition, and it is scarcely compatible with drains operating at the lower end of the capillary tubes. Drainage dogmas also require modification, in so far, at least, as they declare the removal of water—which is surely antithetic to capillarity—and the opening up of a path for the entrance of atmospheric air to be the chief functions of drains. Plants can live in water, but not in an atmosphere of carbon dioxide; a fertile soil is as prolific a source of this gas as the brewer's fermenting tun, and but for the presence of drains—i.e. the removing *per descensum* of carbonic acid—no plant could grow. It is also maintained that the entrance of carbon dioxide is essential because of its function as a soil solvent; but from what has been said it is evident there is something wrong with the theories. Free entrance of oxygen to soils is necessary for root life, and that is the reason why removal of the over-abundant carbonic acid becomes imperative; but it is not the case that it is necessary to nitrification, and the leguminosæ can grow robustly in what is practically an atmosphere of carburetted hydrogen, so long as calcium carbonate is maintained in the surface soil. Strange as this may seem, it has been demonstrated on fields in Midlothian; and the fact goes to show that the nitrifying organisms in soils can produce from calcium carbonate all the oxygen required by them for their life and work. This, indeed, is one of the great functions of lime in soils. Lime cannot be replaced by magnesia in soils, nor magnesia by lime: thus in fruit formation lime cannot perform the functions of magnesia, while lime—in addition to its all-importance as a salifiable base—becomes the great carrier of food-stuffs into the plant, where again it is of paramount importance as a fixer of the acid product of the oxalic fermentation, in which rôle magnesia is useless.

An article on soil formation would be incomplete if reference were not made to the important part played by earthworms (*Lumbricus terrestris* especially; see EARTHWORMS); but while they bring up much valuable material from the subsoil, they are great robbers of lime from the surface soil.

The views above stated are more fully treated in a work on the subject by the present writer and Mr A. N. M'Alpine (1892). There are also works by Scott Burn, Fream, Scott and Morton, Johnson, Munro and Wrightson, Brannt, &c. See also AGRICULTURE, MANURES, NITRIFICATION, &c.

Soissons, a town and fortress of France, dept. Aisne, stands on the river Aisne, 65 miles NE. of Paris by rail. Soissons is the key of Paris for an army invading France from the Netherlands, and is the meeting-point of several military roads. The principal building is the cathedral, founded in the 12th century, the library of which contains many rare MSS. There are also some remains of the great castellated abbey of St Jean des Vignes (1076), where Thomas à Becket found refuge when in exile. The church of St Peter (Romanesque) dates from the 12th century; there are slight remains of the once celebrated abbey of Notre Dame (founded 660) and of the abbey church of St Léger (1139). Quite near to Soissons is an institute for deaf and dumb, which occupies the site of the famous abbey (560) of St Médard, where Clothaire and Siegbert were buried. The civil buildings embrace a college and a museum of antiquities. Pop. 11,850, who carry on varied industries. Soissons is one of the oldest towns in France, and was celebrated even in the time of the Romans, when it bore the name first of *Noviodunum*, and afterwards of *Augusta Suessionum;* hence its modern name of Soissons. It was the second capital of Gallia Belgica, and subsequently the most important town of the Romans in northern Gaul. Near to it Clovis overthrew Syagrius, the Roman commander, in 486. The same prince made Soissons the seat of the Frankish monarchy of Neustria. Here Pepin was crowned king, and Louis the Pious imprisoned. It was the gathering-place of more than one important council and has been repeatedly captured and sacked in war—e.g. six times during the Hundred Years' War, by the Armagnac party in 1414, by Charles V. (1544), the Huguenots (1565), three times in 1814, and by the Germans in 1870.

Soke, a form of the word *Soc*, meant in old English times both the privilege of holding a court and the territory in which such privilege was exercised, or a district held by tenure of Socage (q.v.).

Sokoto, an independent kingdom of Central Africa, having the Soudan on the north, and the river Benue along the greater part of its southern boundary; while on the east and west it has the native kingdoms of Bornu and Gandu respectively.

The area is stated to be nearly 200,000 sq. m. The country is generally level, but rises to 10,000 feet in the province of Adamawa; and it is well watered by the Benue and its tributaries. There are large deposits of good iron. The inhabitants number 10 or 12 millions. The ruling race are the Fulahs (q.v.); their subjects Haussa (q.v.) and various Negro tribes. In 1885 the sultan of Sokoto put his kingdom under the protectorate of Britain, and granted to the Royal Niger Company a monopoly of the trade. The *town* of Sokoto, in the north-west corner of the kingdom, shares with Wurnu, 18 miles east, the rank of capital. Near it Clapperton died (1837); and Sokoto has also been visited by Barth (1853), Rohlfs (1866), Flegel (1880), and J. Thomson (1885).

Solanaceæ, or SOLANEÆ, a natural order of exogenous plants, mainly herbaceous plants and shrubs, but including a few tropical trees. The leaves are mostly alternate, undivided or lobed, without stipules. The flowers are regular, or nearly so; the calyx and corolla generally five-cleft; the stamens generally five. The fruit is either a capsule or a berry, usually two-celled. The plants of this order are mostly natives of tropical countries, a small number extending into the temperate climates; in the coldest regions they are entirely wanting. They are mostly distinguished by an offensive smell and by containing a narcotic, poisonous substance, usually associated with a pungent principle, and some of them are amongst the most active poisons. Sometimes the narcotic substance predominates, as in Mandrake (q.v.) and Henbane (q.v.); sometimes the pungent substance predominates, or is alone present, as in Cayenne Pepper (Capsicum); sometimes both are present in more or less equal proportion, as in Tobacco, Thorn-apple, and Belladonna. The fruit is generally poisonous; but that of a considerable number of species, in which acids and mucilage predominate, is eatable—e.g. the berries of the Winter Cherry and other species of Physalis, of the Egg-plant (q.v.) and some other species of Solanum, and of the Tomato (q.v.). The tubers, which occur in a few species, contain much starch, and serve for food, the Potato being the chief example. The seeds of all contain a fixed oil, which in the south of Germany is expressed from the seeds of the Belladonna itself.

Solan Goose. See GANNET.

Sola'num, a genus of plants of the natural order Solanaceæ, containing a great number of species, distributed all over the world, but particularly abundant in South America and the West Indies. Some are herbaceous, others shrubs; some unarmed, and some spiny; many covered with a down of starlike hairs. The flowers are in false umbels, or almost in panicles; seldom in racemes or solitary. The anthers open by two holes at the top. The berries are two-celled, and contain many smooth seeds. The species of this genus almost always contain in all their parts a poisonous alkaloid, *Solanine*, sometimes so much that the leaves or berries cannot be eaten without danger, whilst in a few species the quantity present is so small that these parts are eaten freely, being agreeable and harmless. By far the most important of all the species is the Potato (q.v.), in which, however, solanine is found in considerable quantity, so that not only the herbage, but the juice of the raw tubers, is unwholesome. Of the species with eatable fruit the principal is the Egg-plant (q.v.). The only British species are the Bitter-sweet (q.v.) and Common Night-shade (q.v.), both of which possess poisonous and medicinal qualities. The berries, leaves, bark, and roots of various species are employed for different medicinal uses in warm countries. The berries of *S. saponaceum* are used as a substitute for soap. The fruit of *S. sodomeum*, Apple of Sodom, a native of North Africa, contains a greenish pulp when ripe, which if eaten causes headache, madness, and death. *S. quitoense* yields a wholesome fruit resembling an orange in appearance and somewhat also in flavour. The fruit of *S. muricatum* is eaten in Peru and has the flavour of a melon. The Kangaroo-apple of Australia is the fruit of *S. laciniatum*, which is wholesome when ripe, but poisonous when unripe. The berries of *S. coagulans* are employed in Egypt to curdle milk.

Solar Microscope is an apparatus for projecting upon a screen by means of sunlight an enlarged view of any object. It is essentially the same as the combination of lenses used in the Magic Lantern (q.v.) taken in conjunction with a heliostat. A heliostat is a plane reflecting mirror which by means of clockwork follows the sun's apparent motion so as always to throw its rays in the direction in which they are first adjusted. By this instrument the rays are thrown horizontally into the solar microscope, and are concentrated first by a large lens and then by a small lens upon the small object that is to be projected. As they diverge the rays are collected by an adjustable system of lenses and focussed sharply on a screen. Uncertainty of sunlight very much circumscribes the usefulness of the apparatus. For solar cycle, solar engine, see CYCLE, AIR-ENGINE.

Solar Myth, a myth allegorising the course of the sun; by some mythologists constantly invoked to explain the problems of Mythology (q.v.).

Solar System, the planets and comets which circle round the sun; also called *planetary* system. No change of much magnitude can take place in the elements of the planets without having effect on the earth and its inhabitants, on account of the mutual attractions of the planets for each other; in fact, they appear as members of one family, bound together by common ties, which could not be ruptured in the case of one individual without communicating a general shock to the others. The various members of the solar system, and their motions, are noticed under PLANETS, COMET, SUN, MOON, SATELLITES, METEORS, GRAVITATION, CENTRE, PRECESSION, ECLIPSE, &c., so that it only remains here to tabulate the more interesting numerical facts connected with them.

Name.	Diameter in Miles.	Density, Earth's being = 1.	Mass, Sun's being = 1.	Distance from Sun in Millions of Miles.	Period of Revolution, in Days.	Velocity in Orbit—Miles per Hour.	Velocity of Rotation at Equator—Miles per Hour.	Force of Gravity on Surface (Earth = 1).

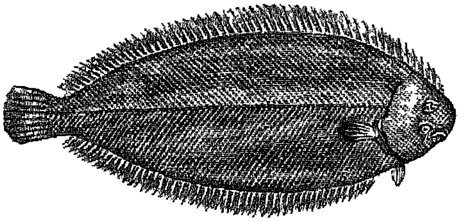
Solder, a fusible alloy used for joining metals. For some of these there are two classes of solders, called hard and soft. Under the head BRAZING the composition of hard solders for brass and copper is given. Common brass makes a solder for iron. 'Silver solders,' which melt at a lower temperature than ordinary hard solders, are used for brass, copper, and sometimes even for iron. One kind is composed of equal parts of silver and brass; another variety consists of these two metals and zinc in equal proportions. These solders are a little costly, but when they can be used they give much satisfaction. The solder used by silversmiths is usually made of two of silver and one of brass. Goldsmith's solder varies with the fineness of gold to be joined, the coarsest kind being formed of three of gold, two of silver, and nearly two of copper; but the proportion of gold is much higher for fine work. Soft solders for brass consist of two of tin and one of antimony, and of lead and tin in equal or nearly equal proportions. The latter is also used for lead, but plumbers use besides a mixture of one of tin to two of lead. For pewter a little bismuth is added to these two metals. A solder of two of tin and one of lead does for zinc. Suitable solders for the above metals can be purchased already prepared. The fluxes usually employed are borax or sal ammoniac for hard solders, and resin, muriatic acid, or Baker's mixture for soft solders.

Soldier. See ARMY, ENLISTMENT, MARTIAL LAW, TACTICS, WAR.—SOLDIER BEETLE is a name given to coleopterous insects of the genus Telephorus, from their red colour and combativeness. —SOLDIER BIRD is an Australian Honey-Eater (*Meliphaga sanguinolenta*), named from the male's crimson plumage. For Soldier-crab, see HERMIT-CRAB.

Soldo. See SOLIDUS.

Sole (*Solea*), a genus of flat-fishes (Pleuronectidæ), distinguished by the following characters: mouth rather small and not terminal, its lips curved on each side towards the ventral edge of the head; teeth present only on the lower or left side, where also the jaws are larger and stronger than on the right; eyes small and not prominent, on the right side, the dorsal anterior to the ventral; scales small, ctenoid—i.e. fringed with spines posteriorly; lateral line straight on the body, but with an anterior dorsal curve on the head; tactile filaments on the lower side of the snout. Paired fins may be rudimentary or absent. The dorsal fin commences on the snout, and is not continuous with the caudal. The shape of the fish is oval, the outline of the snout being semicircular, and projecting somewhat beyond the mouth. The Common Sole (*S. vulgaris*) is a fish of high value in the market, and its price has risen greatly of late years: in 1890 it was over £6 per cwt. at the place of landing. It is captured in the North Sea from Yorkshire southwards, in the English Channel and Irish Channel, and off the south coast of Ireland. Off the Scottish coasts it occurs only in small numbers. Beyond Britain it ranges along the west coast of Europe and throughout the Mediterranean. The largest supply of soles comes from the North Sea, nearly four times as many being landed on the east coast as on the south coast of England, while the west coast produces about the same quantity as the south, the produce of the Irish grounds being included in the former. The Common Sole is the largest of the British species; it is distinguished by the following characters: pectoral fins well developed on both sides, nostrils on the two sides similar, filaments of the lower side of the snout crowded without arrangement. The colour of the upper side consists of longitudinal series of black blotches on a yellowish-brown ground. The sole has been known to reach a length of 26 inches and a weight of 9 lb., but its usual size varies between 10 and 20 inches and its weight from ½ to 2 lb. It spawns in March and April chiefly, but some individuals may shed their ova in May. It breeds on the grounds where it lives, and its ova are small and buoyant. The young, at a very early stage after they have metamorphosed, are occasionally found in tidal pools, but after about 1 inch in length they are probably to be found in deep water. The adults are frequently taken in estuaries in summer time, and have been said to thrive in fresh water, though that is doubtful: they certainly do not breed in fresh water.



Common Sole (*Solea vulgaris*).

The Sand Sole, sometimes called Lemon Sole (*S. lascaris*), is distinguished from the common sole by having specks instead of blotches on its coloured side, and a dilated nostril on the lower side. Its habits are similar to those of the common sole, and it is sent to market with it without distinction, but it is very scarce. The Thickback (*S. variegata*) is found only on the south coasts of England and Ireland, extending thence to the Mediterranean. It is smaller than the two previous species, seldom exceeding 9 inches in length. It is distinguished by its rudimentary pectoral fins, and its markings of dark transverse bands on a reddish ground. The Solenette (*S. lutea*) is the smallest British species; it has rudimentary pectorals, and markings like the common sole, with the addition of a black line along every fourth or fifth fin-ray in the dorsal and ventral fins. It is common both in the North Sea and on the south coasts; it does not exceed 5 inches in length. There are a large number of species of Solea in temperate and tropical seas all over the world, but no others are of value as food. There are no soles of any value on the Atlantic coast of the United States. There are numerous closely allied genera. Synaptura is distinguished by the continuity of the longitudinal fins with the caudal; it includes the curiously marked East Indian *Synaptura zebra* mentioned by Cuvier, which is reddish olive, with twelve pairs of transverse brown bands. In some species of Solea and allied genera the pectorals are absent altogether. See *A Treatise on the Common Sole*, by the present writer, J. T. Cunningham (1890).

Solebay. See SOUTHWOLD.

Solecism. A solecism is the term applied to any violation of the grammar or idiom of a language, or of the usages of society. The word (Gr. *Soloikismos*) is derived from the city of Soli in Cilicia, whose inhabitants spoke very bad Greek, in consequence of their intercourse with the Cilician natives, and provoked the fastidious Athenians to coin the epithet.

Solen. See RAZOR-FISH.

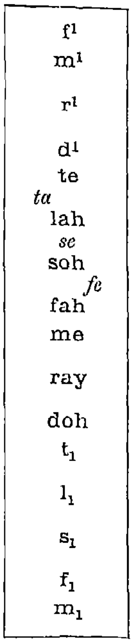
Solenhofen Stone. See ARCHÆOPTERYX, LITHOGRAPHY.

Solenoid. See MAGNETISM, Vol. VI. p. 798.

Solent, the western portion of the strait that intervenes between the Isle of Wight and the mainland of England. It is 17 miles long, and about 3 in average breadth, but contracts to ¼ mile at Hurst Castle (1535), built by Henry VIII. to guard its entrance on the south-west; and here the tide flows with a rapidity which at certain times no boat can stem.

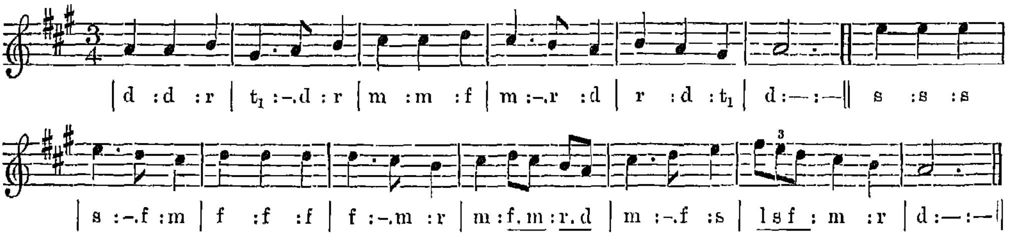
Soleure (Ger. *Solothurn*), a canton in the north of Switzerland, bounded on the W. and S. by Bern, and on the N. and E. by Basel and Aargau. Area, 306 sq. m.; pop. (1880) 80,424; (1888) 85,621, mostly Roman Catholics and speakers of German. The greater portion of the canton is fertile and well cultivated, especially in the valley of the Aar. But it also embraces outlying ranges of the Alpine and Jura systems. Besides grain, the principal products are fruit, timber, cherry-brandy, cheese, cotton, paper, iron, hose, clocks, &c. The canton consists of the territories acquired by the town of Soleure. The legislative council is elected by the people, and that body chooses the executive (5 members), both for four years. But both bodies are subject to the immediate control of the people, as well as every act they do, by means of the referendum.—The *town* of Soleure, the capital of the canton, is situated on both sides of the Aar, 18 miles NNE. of Bern by rail. The most notable building is the cathedral of St Ursus, built in 1762-63 on the site of an older church (1050), with a cupola and façade of Corinthian columns. There are also a curious old clock tower, an arsenal with a museum of ancient trophies of war, and collections of antiquities. The principal objects of industry are cotton, clocks, and cement. Pop. 8305. Soleure (*Salodurum*) was a place of some consequence in Roman times, was made a free city of the empire (1218), joined the Swiss Confederation in 1481, and in 1828 was chosen the bishop's see for the diocese of Basel. Close by are the baths of Weissenstein, with a celebrated 'whey-cure' that is very much frequented.

Sol-fa System. Attempts have been made at various times to introduce a musical notation in which the staff with its lines and spaces is dispensed with. Jean Jacques Rousseau suggested, but afterwards discarded, a notation where the notes of the scale were indicated by the Arabic numerals—a principle which is the chief feature of the Chevé system, now largely used in France. A system similar to Rousseau's in its leading features, called the Tonic Sol-fa, has been brought into use in many singing-schools in Britain and America—its chief promoter being the Rev. John Curwen (q.v.), who obtained his main principles about 1840 from Miss Glover, a teacher at Norwich. It is believed that now a million and a half of children are learning to sing on this method in British primary schools. The system proceeds on the principle of giving the chief prominence to the fact that there is in reality but one scale in music, which is raised or lowered according to the pitch of the key. The seven notes of the diatonic scale are represented by the Solfeggio (q.v.) syllables, or rather Miss Glover's modification of them—*Doh*, *Ray*, *Me*, *Fah*, *Soh*, *Lah*, *Te*; *Doh* standing for the keynote in whatever key the music is written. In the early exercises the pupils are accustomed to a scale or diagram, called the Modulator, representing pictorially the exact intervals of a key, with the semitones in their proper places. In written music only the initial letters of the solfeggio syllables are used—d, r, m, f, s, l, t; the higher octaves of a given note being distinguished by a ^{1} above, as d^1, r^1; and the lower by a $_1$ or $_2$ below, m_1, m_2. The name of the key is prefixed to a tune as its signature, as 'Key A,' 'Key B flat'—the keynote being, in all the major keys, *doh*. To indicate rhythm a perpendicular line | precedes the stronger or louder accent, a colon : the softer accent, and, where necessary, a shorter perpendicular line | the accent of medium force. A note immediately following an accent mark is supposed to occupy the time from that accent to the next. A horizontal line indicates the continuance of the previous note through another pulse or beat. A dot divides a pulse into equal subdivisions. A dot after a mark of continuance indicates that the previous note is to be continued through half that pulse. A comma indicates that the note preceding it fills a quarter of the time from one accent to the next; a dot and comma together three-quarters. An inverted comma ‚ is used to denote that the note preceding it fills one-third of the time from one accent to the next. An unfilled space indicates a rest or pause of the voice. A line below two or more notes signifies that they are to be sung to the same syllable. We subjoin an example of the tonic sol-fa shown alongside of the ordinary notation, and illustrating most of the features named:



Modulator.

KEY A. GOD SAVE THE QUEEN.



| d :d :r | t_1 :–.d :r | m :m :f | m :–.r :d | r :d :t_1 | d :— :—‖ s :s :s

| s :–.f :m | f :f :f | f :–.m :r | m :f.m :r.d | m :–.f :s | l s f : m :r | d :— :—‖

In modulating into a new key the note through which the transition is taken is indicated by a combination of the syllabic name which it has in the old key with that which it has in the new—*me lah*, for example, being conjoined into *m'lah*; and in writing this note (termed a bridge note) the initial letter of its syllable, as a member of the old key, is placed in small size before and above the initial of the syllable of the new, as ml, ds. In the case, however, of an accidental, where the transition is but momentary, a sharpened note changes its syllabic vowel into *e*, and a flattened note into *aw*, spelled *a*, as *fah*, *fe*; *soh*, *se*; *te*, *ta*. In the minor mode *lah* is the keynote; the sharp sixth is called *bah*, and the sharp seventh *se*. The signature of the key of A minor is 'Key C, minor mode.' The time-names of the French Chevé system have lately been adopted. The method of teaching, based on a wide experience, is of equal importance with the notation itself.

For a full explanation of this system, see Curwen's *Course of Lessons and Exercises in Tonic Sol-fa.* Its advocates maintain that it possesses advantages over the common system in the facility of its acquisition; the distinctness with which it indicates the keynote and the position of the semitones; the cheapness with which it is printed; and the manner in which, they say, it explains the proper mental effects of notes in harmony and key-relationship, and employs them in teaching. It has, however, been objected to by others, from its withdrawal of the direct indication of both absolute and relative pitch to the eye which exists in the common notation, from its limited applicability to instrumental music, and from its acquirement not being, like that of the ordinary notation, an introduction to the world of musical literature. It presents, however, no barrier, but rather a road to the acquisition of the older notation; and its widespread use and the testimony of the general body of practical teachers are eloquent arguments in its favour. Of the children in English primary schools who can sing from notes 80 per cent. learn on this system, which has practically ousted the 'Fixed Do' system of Hullah, its rival in earlier days. The Tonic Sol-fa College, founded in 1869, with its system of examinations, carries on a vast amount of useful work.

Solfata'ra (Fr. *Soufrière*, Ger. *Schwefelgrube* or *Schwefelsee*), the Italian names for such volcanoes as, having ceased to be violently active, emit from crevices gases, steam, and chemical vapours, chiefly of sulphurous origin. The most notable are found in Italy, in the Antilles, in Mexico, in the interior of Asia, and in Java. Probably the best known are those between Rome and Tivoli, and that at Pozzuoli (q.v.), near Naples. This last is an irregular plain almost surrounded by the walls of an ancient crater. From the crevices rise steam and gases, chiefly sulphuretted hydrogen, mixed with minute quantities of muriatic acid and muriate of ammonia. The cracks and fissures of the rocks abound with sulphur, alum, and sulphate of iron. The vapours exhaled are used as medicinal baths, which are taken in wooden huts on the spot. The Soufrière of the island of St Vincent, West Indies, about 3 miles in circuit and over 500 feet in depth, was in active eruption in 1880.

Solfeggio, in Music, a vocal exercise, in which the syllables Ut (or Do), Re, Mi, Fa, Sol, La, Si—corresponding to C, D, E, F, G, A, B—are employed in lieu of words. Their use as a method of nomenclature originated, as far as the first six are concerned, in the 11th century with Guido Aretinus (q.v.), who substituted his hexachord system for the old Greek tetrachords. Observing in the melody of an ancient hymn for the festival of St John the Baptist, beginning

Ut queant laxis *Re*sonare fibris
*Mi*ra gestorum *Fa*muli tuorum
*Sol*ve polluti *La*bii reatum
Sancte Ioannes,

that the notes on which the successive phrases began were identical in order with the sounds of the hexachord, he adopted the syllables to which they were allied in the above stanza as names to represent the degrees of his new scale. When, early in the 17th century, the octave was completed by the seventh or 'leading note,' the syllable Si, formed of the initials of 'Sancte Ioannes,' was added; while Do generally took the place of Ut, as being more easily sung. The art of thus illustrating the construction of the musical scale by the use of syllables is called *solmisation*.

Solferino, a village of Northern Italy, 19 miles NW. of Mantua, stands on a hill, and has a tower, called the Spy of Italy, from which the whole plain of Lombardy may be seen. There, on June 24, 1859, the Austrians were defeated by the allied French and Piedmontese—the first named losing 20,000 men, and the allies 18,000. Pop. 1284.

Soli. See SOLCIUM.

Solicitor-general, the name given to one of the law-officers of the crown appointed by patent. The Solicitor general of England has powers similar to those of the Attorney-general (q.v.), after whom he ranks and to whom he gives aid in discharging his functions. His tenure of office in practice terminates with the fall of the ministry of which he is a member. He receives on appointment the honour of knighthood.

The Solicitor-general for Scotland is one of the crown counsel, next in dignity to the Lord Advocate (see ADVOCATE, LORD), and exercising all his functions along with him, but he does so as his deputy and not of original right. An act, however, of 1887 provides that, if the office of Lord Advocate be vacant, indictments may be raised in the name of the Solicitor-general. Like the Lord Advocate, he has the privilege of pleading within the bar. This right was recognised by the court as early as 1662, though it was afterwards lost for some time.
